Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

SUPPLEMENT TO "THE ELECTRICAL ENGINEER," JUNE 29, 1894.

THE

ELECTRICAL ENGINEER.

A WEEKLY JOURNAL OF ELECTRICAL ENGINEERING,

WITH WHICH IS INCORPORATED

"ELECTRIC LIGHT."

VOL. XIII. (NEW SERIES.)

FROM JANUARY 5, 1894, TO JUNE 29, 1894.

LONDON:

Printed and Published for the Proprietors by BIGGS & Co., at "THE ELECTRICAL ENGINEER" Offices, 139-140, Salisbury-court, Fleet-street, E.C.

1894.

Digitized by Google

INDEX TO VOL. XIII. (New Series.)

NOTE.—General Articles, Correspondence, and Companies' Meetings are indicated by heavier type (thus, 290) than the Notes and Business Notes, references to which are shown by light type (thus, 290).

A.

Abatement of Smoke Experiment at Glasgow, 338
A B C, Electrical Students', **464**
Aberdeen Central Station, 216, 246
Accidents, 141, 393
Accumulator, The Fulmen, 657
Accumulators and Government Inspection, 365
Accumulator Cars in Sydney, **751**
Acoustic Synchroniser for Alternators, **263**
Action in Connection with the Niagara Falls Scheme, 130
Action of the Electric Arc on the Diamond, etc., 187
Advice to Young Electrical Engineers, 5
Advertising Dodge, An, 714, 741
Aetna Blow Lamp, 681
African Transcontinental Telegraph, 423
After-Glow in Exhausted Bulbs, 132
Agencies, 333, **334**, 362, 506
Aix-la-Chapelle Central Station, 338
Alarming Intelligence, 741
All British (Leading Article), **260**
All Rights Reserved, 658
Alternate-Current Electrolysis, 632
Alternate-Current Motors, 646
Alternate-Current Rectifiers, 216
Alternating Current and the Low-Tension Distributing Network, E. Parry, **283**
Alternating-Current Transformers, Efficiency of, **638**
Alternators, Acoustic Synchroniser for, **263**
Alternators, Running of, in Parallel, **261**, **293**, **321**
Altona Central Station, 279, 741
Aluminium, Notice of Paper by Mr. Sample on, 129
Amalgamation of Engineering Works, 28
American Institute of Electrical Engineers, 395, 573
A New Danger (Leading Article), **78**
Anglo-American Cable, New, 630
Annual Show of the Royal Agricultural Society, **754**
Another Belt Case, 157
Antwerp Exhibition, 65, 129, 130, 215, 337, 477, 685
Antwerp Hydro-Electric Installation, 339
Any Lessons (Leading Article), **112**
Apparatus for the Measurement of Coefficients of Self-Induction, and the Investigation of the Phenomena of Alternating Currents, F. A. Laws, **693**
Applications for Provisional Orders, List of, **26**
Appointments, 306, 421, 451, 653, 657, 760
Appointments Vacant, 58, 59, **93**, 95, 181, 209, 277, 311, **334**, 416, 506, 538, 568, 569, 598, 625, 655, 680, 736, 737, 738, 759, 760
Arc and Incandescent Lamps, M. A. Bainville on, 577
Arc Lamp for Lantern Exhibition, 98
Arc Horses "Peculiarly Susceptible to Electric Shock," 248
Arsenical Telegraph Batteries, 510
Arts and Crafts Society for Ireland, 573
Ashford Electrical Exhibition, 654
A Silver Lining (Leading Article), **406**
Assessment of City of London Company's Works, 391
Association of Municipal Engineers, **745**
Atlas Carbon Company and Leclanche Batteries, 363
Atmosphere, The Potential of, 97
Atmospheric Electricity, Utilisation of, 541
Aurora and the Telegraph Wire, 395
Australia-New Caledonia Cable, 1
Automatic Cut-out for Large Currents, **325**
Automatic Electric Signals, I. A. Timmis, **634**
Automatic Regulator for Dynamos, 544
Awards, 473, 601

B.

Babolna, Electric Power Pumping Station at, 601
Balruddery, Electric Organ, 680
Barnes, Mr., On Electric Railways, F. B. Lea, **609**
Battersea Polytechnic, 2, 157, 247
Beaumont, W. W., Paper on Vibration at the Society of Arts, 160
Bete Noire of Electric Supply Companies, 479
Bicycle Electric Railway, 277
Bill for Exempting Tenants' Machinery from Rating, 509, 541
Birmingham and Midland Institute, Conversazione at, 29, 63, 68
Blackpool Central Station, J. Hesketh, **199**
Blackpool Tramways (Leading Article), **142**
Bluffing and Hedging, (Leading Article), **586**
Board of Trade and Electric Traction, **134**, **270**
Board of Trade's Proposed Regulation for Electric Railways, **359**
Board of Trade Report for 1893 on Electric Light Provisional Orders and Tramway Orders and Bills, **385**
Board of Trade and Electric Tramways and Railways, Official Regulations for Tramways, **358**
Board of Trade and High Pressure, 97
Bockenheim Central Station, 341
Boiler Incrustations and Deposits, 35, 686
Bonneau and Desrozier's Electric Locomotive, **578**
Book of the Fair (Chicago), 246
Books Received, 65, 158, 245, 309, 311, 511
Bournemouth Accident, 35, 186, **196**, 274, 275, 391
Bournemouth and the Hermite System, 213
Bradford Corporation Electricity Supply, **330**, **745**
Bradford County Council Scholarships, 658
Bradford Scientific Society, Conversazione of, 97
Branding Bacon by Electricity, 538
Breaking up of City Streets, 58
Bridgend Chamber of Commerce and Cost of Provisional Order, 393
Bridgman, Mr., and St. Pancras *v.* City Lighting, 599
Brighton Demand Indicator (Wright's), 422
Brighton Sea-shore Railway Company, 27
Brilliantly Lighted Avenue, A, **458**
Bristol Electric Time Check, 574
British Association, 158, 512, 630, 715
Brush Discharges in Gases, Some Notes on, 278
Brussels Exhibition, 393
Brussels Municipal Electric Light Station, **379**
Budapest, Electric Exhibition at, 393, 421, 742
Budget Item, 449
Burglar Alarm, Siemens, **701**
Burton-on-Trent Electric Light Station, **663**
Business Changes, Partnerships, etc., 27, 241, 274, 446, 598, 681, 759, 760
Business During 1893, **18**, **49**

C.

Cable, A New, 1
Cable Interruptions and Restorations of Lines, 632

THE

ELECTRICAL ENGINEER.

No. 1, Vol. XIII. LONDON, JANUARY 5, 1894. PRICE 3D.

NOTES.

English-Made Carbons.—It is noteworthy that electric light carbons are now being made in England.

Gainsborough.—The suite of rooms erected for the purposes of art and science classes are lighted throughout with the electric light.

The Shipley Tramways.—The Board of Trade has held an enquiry as to the application of the Shipley Local Board to acquire the tramways.

A New Cable.—The Eastern Extension Telegraph Company is reported to be on the point of laying a cable between Hong-Kong, Labuan, and Singapore.

Patents.—During the past year applications for the grant of British patents for inventions were more numerous than in any previous year, the number being 25,102.

Lighting of Baths.—The Newington Vestry, who propose to erect baths and wash-houses in Manor-place, Walworth, intend to spend £500 on lighting the buildings by electricity.

Central London Railway.—The extensions of time desired by the Central London Railway Company are respectively two and three years beyond the time originally granted by Parliament.

Those Tickers Again.—It is stated that the Stock Exchange Committee has confirmed the recommendation of the sub-committee, that the use of tape prices should be under the committee's control.

Lighting of St. Paul's.—The authorities of St. Paul's Cathedral, it is stated, have definitely decided to introduce the electric light. In Easter week an appeal will be made to the citizens to defray the expense.

The "Proper Position" of Gas.—Lord Ernest Hamilton states that "gas as a lighting agent is being gradually superseded by electricity, and will ultimately be relegated to its proper position as a simple heating agent."

Australia-New Caledonia Cable.—It is stated that during the first three weeks' operation of this cable only 45 telegrams were sent through it, each way, at 1f. 10c. per word. A correspondent submits that this can hardly be regarded as a lucrative business.

The Institution.—An ordinary general meeting of the Institution of Electrical Engineers will take place at 25, Great George-street, Westminster, on Thursday next, the 11th inst., when the president, Mr. Alexander Siemens, M.I.C.E., will deliver his inaugural address.

The "Medical Battory Company," Limited.—At the Marlborough-street Police Court, on Wednesday, Mr. Hannay resumed the hearing of the charges of conspiracy to defraud brought against Mr. Harness, Mr. McCully, and Mr. Hollier. Further evidence was adduced and the hearing again adjourned.

Dust Collectors.—A Boston firm suggests that early every morning large cars should be sent over all the lines of the electric railways, and that garbage and refuse gathered along the way should be shoveled into them. Large watering cars would follow these dust collectors.

"Indian Engineers' Diary."—The publishers of the *Indian Engineer* have forwarded us a copy of the "Indian Engineers' Diary and Reference Book for 1894." A lot of useful information is given in the book, which is specially intended for those connected with engineering in India.

Personal.—Mr. Haydn T. Harrison has resigned his position of manager of the testing and standardising department of the Electrical Standardising, Testing, and Training Institution, Faraday House, Charing Cross-road, to enter into partnership with Mr. N. F. Nalder to carry on the business of electrical engineers.

New Year Honours.—Mr. W. H. Preece, F.R.S., engineer-in-chief to the General Post Office, and Mr. J. Norman Lockyer, F.R.S., professor of astronomy in the Royal College of Science, have been appointed Knight Commanders of the Bath. Mr. R. Hunter, the solicitor to the Post Office, has been created a knight.

"Calvert's Mechanics' Almanack."—We have received a copy of "Calvert's Mechanics' Almanack and Workshop Companion for 1894." The almanack, which has now reached its twenty-first year of publication, contains practical and technical information useful to artisan and handicrafts and those generally engaged in mechanical, engineering, building, and constructive trades. It published by Messrs. J. Heywood, of Manchester and London.

Cylindrical Copper Conductor Resistance for Alternating Currents.—With reference to the article published in our last issue, page 613, M. Hospitalier writes making some corrections. He states that in the nineteenth line of the second column the words "frequency in seconds" should read "frequency in periods per second." In the fourteenth line of the same column the words "product diameter by frequency" should read "product of the square of diameter by frequency."

Traction at Hull.—The Electric Lighting Committee of the Corporation have had presented to them a report on the application of electricity as a motive power for the tramways. It was decided to appoint a sub-committee to watch the employment of electricity in this direction, and a resolution was passed requesting the town clerk to insert a clause in any agreement with a new tramway company, binding such company to use the current supplied by the Corporation for operating the cars.

Another Gas Explosion.—Judging from the explosions which have recently occurred, the gas in Glasgow seems to be very partial to the electric lighting mains. We recorded one explosion last week, and another has since taken place, this being last Friday. It appears that three men were

Digitized by Google

working at a manhole in West George-street repairing one of the mains at a point where there was an accumulation of gas, and a light being used an explosion resulted. Two of the men working at the time are reported to have been severely injured about the head and hands, and the third man was slightly burned.

Charing Cross-Hampstead Railway.— The Charing Cross, Euston, and Hampstead Railway Company, which was incorporated last year with powers to construct an underground electric railway from Charing Cross to Hampstead, with a branch line to Euston, have deposited a Bill for next session of Parliament, under which the company seek for powers to acquire, in addition to that authorised last year, important properties situated in the Strand, Villiers-street, Buckingham-street, Oxford-street, High-street, Camden-road, Kentish Town-road, Melton-street, Drummond-street, and Cardington-street.

Bequest.—The sum of £600 per annum has been bequeathed to the trustees of Mason College, Birmingham, by the late Mr. Aubrey Bowen, of Melbourne. The testator stipulates that the trustees shall, within a reasonable time, undertake to apply the sum in founding six scholarships of £100 a year each in connection with the college, to be called respectively the First, Second, and Third Bowen Scholarships, for the promotion of the study of metallurgy, and civil, mechanical, and electrical engineering; and the First, Second, and Third Priestley Scholarships, for the promotion of the study of chemistry.

A New Electrical Vehicle.—A new electrically-propelled carriage, according to *Industries*, is being introduced by M. Paul Pouchain, of Armentières, France. The carriage will carry six persons. The electrical energy is supplied by a battery of 54 Dujardin accumulators. The motor is of the Rechniewski type, with an output of 2,000 watts. It is fixed in the centre of the vehicle, and transmits its power by chain gearing to the driving wheel. According to the inventor, the total weight of the carriage and equipment is about $1\frac{1}{3}$ tons. One charge of the accumulators is sufficient for a journey of about 44 miles at a speed of 10 miles per hour.

Electric Traction at Budapest.—It is announced that the company which owns all the tramways in Budapest, having altogether a length of about 56 miles, has resolved to adopt electricity as the motive power over the entire system. The conversion of the system, it is computed, will take three years to complete. The total cost of the change is estimated at £1,000,000. Whilst the Government and Municipality there are vying with each other in such improvements in the means of transport, the authorities in Vienna, remarks a correspondent, treat that important interest with strange indifference. There are whole districts, especially in the suburbs of this capital, which are still without the convenience of a tramway, or have only partial and very insufficient accommodation of that kind. The populous outer suburbs of Vienna were incorporated with the city three years ago, yet up to the present moment nothing has been done to unite them actually by means of tramways.

Electric Traction in Dublin.—The Dublin Southern Tramways Company have obtained sanction to introduce electricity as a motive power, and this means, according to a local paper, that passengers will be carried to Dalkey for sixpence in 40 or 50 minutes. The additional capital required to carry out the scheme for running the cars by electricity is estimated at from £100,000 to £150,000, and as the project is a local one, and calculated to benefit a large section of the population of the city and suburbs, it is looked forward to with hopeful anticipations. Some time since a bold proposal was made, which, now that so much has been said about a railway for Clontarf, is well worth considering. The plan was to construct a cable line from Howth to Dollymount, and then to have electric cars to the city. The cars, descending from an elevated point at Howth, would by gravity derive sufficient motion to reach Dollymount and to pull the cars from Dollymount up to the point of starting at Howth. This would shorten the journey very considerably between the city and this splendid outlet.

The Battersea Polytechnic.—The doors of this polytechnic were to be thrown open for the reception of students yesterday evening. The formal inauguration of the institute by the Prince of Wales will take place in the course of this or next month. Many of the classes will prepare for the examinations of the Science and Art Department and the City and Guilds of London Institute, and special courses have been arranged applicable to various trades and industries, the institute offering certain scholarships and prizes open only to students attending such courses. The institute contains nearly 100 classrooms and other apartments, chief among which are well-equipped laboratories for chemistry, physics, mechanics, and electrical engineering. In addition, there are well-fitted workshops for woodwork, ironwork, brickwork, and masonry, and the engineers' workshop contains examples of all ordinary machines and tools, and a small smithy. A steam-engine of 100 h.p., a gas-engine of 20 h.p., and two dynamos, with accumulators and other appliances, are also available for teaching purposes.

The Hermite Process at Worthing.—As mentioned in our issue of the 22nd ult., the Hermite system of treating sewage with electrolysed sea-water is about to be experimented with at Worthing. A yard in West-street, near the sea, has been placed at the disposal of the Corporation for this purpose. Two alternative schemes have been sketched out for the treatment of the borough sewage should these tests work satisfactorily. The first is to convey sea-water into the new main sewer at the west end of the town, and the other is the supply of the water through mains to every house in the town in lieu of fresh water *viâ* the flushing-cisterns. For the purposes of the trial temporary closets will be erected in the West-street yard, here also the plant and machinery will be placed and the sewage at once dealt with. M. Hermite has undertaken to carry out the trials, which will extend for a month, for £200. In addition to the temporary closets to be erected, it is proposed to disconnect four houses from the sewer, and the discharge, after being conducted to receiving-tanks, will be treated in full view.

Liverpool Overhead Electric Railway.—It is satisfactory to note that this railway, which was started for traffic in March last, has now been taken over from the contractors, the Electric Construction Company, Limited. The contractors were under an obligation to work the line for two years from the date of opening at a fixed rate of 4d. per train mile, but the working has been so satisfactory that the railway company have decided to take over the line as from the 1st inst., and the electrical company are relieved from all responsibility of the working and maintenance. The railway company contemplate putting into execution the powers they have of creating four new stations at the north end of the line. Two of the new stations will be opposite the Trafalgar and Nelson Docks respectively, a third at Sandhills-lane, and the fourth at Langton-street. The company are also proceeding with the extension of the line to Seaforth, where a very fine station is to be be built, of the Pierhead type, but completely roofed in. Several improved carriages are to be constructed of the most modern type.

Digitized by Google

Long-Distance Telephony.—Some time ago an arrangement was come to between the Postmaster-General and the National Telephone Company whereby Dundee subscribers to the company's system could have the advantage of telephonic communication with the company's subscribers in Belfast and Dublin *vid* the Post Office trunk wires between Belfast and Glasgow. Several firms in Glasgow have already availed themselves of the arrangement, whilst one firm in Dundee has followed the example. The Post Office charge for a three minutes' use of the trunk wire between Glasgow and Belfast is 3s. Thus, should a subscriber in Dundee desire to communicate with Belfast he may do so on payment of 3s. 9d., the additional 9d. being the charge for the use of the company's trunk wire between Dundee and Glasgow. Dublin may be communicated with on payment of an extra shilling, while communication may also be established with several other towns in the North-East of Ireland. With a view of still further improving the service, the telephone company have decided upon entirely reconstructing the switchboards in their Dundee exchange.

Society of Arts.—The ordinary meetings will recommence on Wednesday evening, the 17th inst., when Mr. A. P. Laurie will read a paper on "White-Lead Substitutes." The arrangements for the succeeding Wednesdays are as follows: January 24, "American Carriages," by Mr. G. Herbert Thrupp; January 31, "Californian Wines," by Mr. Charles P. Oldham; February 7, "Reproduction of Colours by Photography," by Captain Abney, C.B., F.R.S.; February 14, "The St. Pancras Electric Light Installation," by Mr. Henry Robinson, M.I.C.E.; February 21, "Electric Signalling Without Wires," by Mr. W. H. Preece, C.B., F.R.S. The next course of Cantor lectures will be delivered on Monday evenings, January 22, 29, and February 5, 12, by Prof. Frank Clowes, D.Sc., the subject being "The Detection and Measurement of Inflammable Gas and Vapour in the Air." Mr. Hugh Stannus, F.R.I.B.A., will give a course of Cantor lectures on "The Decorative Treatment of Traditional Foliage" on February 19, 26, and March 5, 12. Further Cantor lectures will be delivered by Captain Abney on "Photometry," and by Mr. H. C. Jenkins on "Typewriting Machines."

Electric Lamps on the District Railway.—In our last issue appeared a note on train-lighting, in which it was stated that "The intention was that the light should only fall on the book or newspaper of the person who dropped in the penny; but the apparatus is said to be so placed that when the compartment is full the light neither benefits the person sitting next the window nor his next neighbour, but falls between the two." Mr. J. Tourtel, managing engineer to the Railway Automatic Electric Light Syndicate, Limited, of 37, Walbrook, E.C., has written to correct this statement. He says: "This is quite incorrect, as our reflectors being movable, a man is able to direct the light upon his paper in any desired position. Some people prefer to operate by a method of their own, totally regardless of directions: some press the knob without inserting a coin; some insert the coin and omit to press; while some, who succeed in obtaining a light, omit to adjust it to suit their convenience, and occasionally, through the Press, they unconsciously proclaim their deficiency in intelligence. Fortunately, however, such people are rare."

Electrical Communication with Lightships.—The necessity for a method of communication between lightships and the shore is becoming manifest in the United States, as has been the case in this country. Included in the recent estimates submitted to Congress is £10,000 for establishing electrical communication in this direction. Appended to the estimate is a note stating that: "The House of Representatives Committee on International and Foreign Commerce on December 6, 1892, asked the views of the Treasury Department as to the Bill appropriating £10,000 to provide communication from lightships and outlying lighthouses to the shore. Favourable reply was made on December 8, 1892. Since then the Lighthouse Board has experimented, and is now satisfied that it can establish electric communication between lightships and shore. It is proposed to commence with an important lightship quite near shore, then take a more important one more distant, and then, if need be, another still further away, and thus acquire by successive efforts the experience needed to successfully lay an electric cable to connect with the shore the most distant and important lightship—that on the New South Shoals, some 30 miles off Nantucket, Mass."

Prize for an Essay on Wind Power.—The Netherland Society for the Promotion of Industry, the secretary of which is Mr. F. W. van Eeden, of Haarlem, Holland, offers its prize for 1894 for papers indicating the method of obtaining energy by means of windmills, to accumulate this energy electrically, and to transmit it or make it portable. An answer to the following questions is more particularly desired: (1) What is the average energy a common windmill is able to produce, per day of 24 hours, in combination with an electric accumulator; what would be the installation most suitable to this effect, and what would be the cost of one horse-power hour? (2) Is it possible, from an economical point of view, to apply the new aerial motors on an extensive scale for the accumulation and the utilisation of this energy? If so, what mechanical appliances would be required for this purpose? The project of a supposed application of the system by which a factory is provided with light and power, is wanted as an illustration. The drawings belonging to the answers must be made on white paper on a scale of ¼in. to the foot. The prize comprises the gold medal of the society and the sum of £30. The papers are to be sent before July 1, with the author's name in a closed envelope, to Mr. F. W. van Eeden, of above-mentioned address.

Railway Rates.—Sir Albert K. Rollit presided at a meeting of the London Chamber of Commerce on Wednesday, when the report of the Select Committee on Railway Rates was discussed. The Chairman said the report was not all that the traders might have wished, but it contained much which, through Parliament, might be made beneficial and useful. It certainly was material for legislation, and their chief object should now be to press as rapidly as possible before the House of Commons the recommendations of the committee. Mr. Edgar Howell moved, "That this meeting, having considered the report of the Select Committee on Railway Rates, expresses satisfaction with the recognition, to a great extent, of the contentions of traders therein contained, and of the recommendations made, so far as they recognise the necessity of providing means for a speedy determination of what is and what is not a reasonable actual rate." The resolution was seconded by Mr. S. B. Boulton, supported by Mr. Burnie, M.P., and carried unanimously. On the motion of Mr. Thomas Blackwell, seconded by Mr. Rosenfeld, it was decided to recommend traders to communicate without delay to the Board of Trade, through the London Chamber of Commerce, the amount of their claims against the railway companies, whether in respect of deductions made from railway accounts or charges actually paid.

A Handsome Electric Light Column.—Recently the huge wooden casing in front of Wanamaker's, in Philadelphia, was taken down, and there stood revealed a

Digitized by Google

handsome column of incandescent bulbs, with broad spiral stripes, each of a different colour—white, blue, purple, orange, green, yellow, and crimson predominating. The column is about 25ft. high, and from it extend four long arms lined with rows of glass bulbs of different colours, two of the arms in the side aisles terminating in 25 bulbs each, and two in revolving balls of 266 bulbs each, all handsomely coloured. At intervals of a few seconds, each stripe flashes with light, one brilliant colour swiftly following another until the top of the column is reached, when the varying light is diffused along each of the arms until the two large bulbs are reached, where the flashing continues until all the colours are shown. Meanwhile the two large balls are kept revolving, and flash continuously with varying lights and colours. The whole affair, whose effect is very pretty, is ingeniously managed from a switchboard in the basement under the column. As the lights change from one colour to another they go out completely, leaving no lingering glow in the carbons to spoil the effect, as would be the case were it not that this has been guarded against by a current of air being ingeniously injected automatically by the machine. The arrangement was a part of the famous electrical display at the World's Fair.

Electro-Tanning.—In a recent issue we mentioned that Mr. L. A. Groth had gone to Orbe, Switzerland, to establish his system of tanning in Mr. Rod's tannery there. The place intended for the new tannery is being obtained by blasting away the rocks facing the River Orbe, and this work was commenced last July. The first part of the buildings is estimated to be finished at the end of this month, when the tanning, we are informed, will commence with 300 hides per week, whilst the whole tannery, when finished, is estimated for a turn-out of 1,000 hides per week. The machinery for finishing the tanned hides into the various kinds of leather has already been ordered. The motive power required will be obtained from a waterfall of about 3,000 h.p., situated nearly two miles distant. There are installed two turbines, each of 300 h.p., acting upon dynamos from which the power is electrically transmitted into the town of Orbe, partly for lighting, which commenced on the 1st inst., and partly to be used as motive power for the large flour mill and tannery, both belonging to Mr. Rod. The electric railway from Orbe to Chavarnay railway station is also driven by the same power. The quality of the leather tanned by the Groth process is shown by Prof. Unwin's tests, the last one, dated October 26, 1893, being as follows: "Marked; Leather tanned in five weeks by Groth's system, Orbe, Switzerland, October 20, 1893, Jules Rod. Dimensions, 3·85in. wide by 0·2in. thick and 16in. long. Maximum load, 1·795 tons. Breaking stress, 2·3 tons per square inch of section, or 1,044lb. per inch of width. It stretched permanently 6 per cent. in 10in. The leather is rather above the average strength of good leather belting."

Repairing Edison Lamps is an Infringement.—The United States Circuit Court of Massachusetts has granted an injunction against the Davis Electrical Works, of Springfield, Mass., restraining the latter from repairing lamps under the Edison patent by substituting a new filament. The Court states that the process of repairing consists in first breaking off the tip of the glass bulb of the lamp and reaming out a hole about ½in. in diameter. The broken filament is then removed. The new filament, having its ends cemented into platinum sleeves, is then inserted into the glass chamber, the sleeves being pushed down over the two platinum leading-in wires and compressed upon them. A tube of glass made into the shape of a funnel is heated and placed over the hole in the lamp chamber. This tube is fused into the open end of the bulb, which brings it into the condition of the ordinary lamp bulb just prior to exhaustion. The air is then exhausted and the bulb sealed. It is evident, the Court decides, that this operation covers many of the constructive features of the ordinary lamp, whose claim consists of four elements: a carbon filament, a receiver made entirely of glass, conductors passing through the glass, and a receiver from which the air is exhausted. The Court decides that it is apparent that the defendants by substituting a new filament, making over the glass receiver, and exhausting the air from such receiver, produce a lamp in which all the elements but one (the leading-in wires) of the patented combination are used either in a new or reconstructed form. The lamp thus produced is substantially a new lamp, and its voltage may be higher or lower than the old one. From the very nature of the Edison invention, the Court does not see how the glass bulb can be opened and a new filament inserted without making essentially a new lamp.

Signalling Between Trains in Motion.—Some time ago we referred to a system of automatic railway signalling by electricity invented by Mr. Martin Perls, and it was mentioned that this system was about to be tried on some of the military lines in Germany. The trials took place on the 23rd of October last, and a report upon them has been read before the Verein für Eisenbahnkunde by Herr Bormann. The apparatus consists of a battery carried by each locomotive and connected, by means of metallic brushes, with a series of conductors laid parallel to the metals. The circuits are so contrived that two trains travelling upon the same metals, whether in the same or opposite directions, are warned of each other's position by the ringing of a bell on each locomotive, while, at the same time, the two drivers are brought into telephonic communication. The same thing occurs if one of the trains be stationary, so that drivers receive notice of any breakdown upon the line in front of them. The breaking away of a carriage or carriages from the rear of a train is also notified both to the driver and to the station which the train has last passed through; and the distances at which all these warnings are given and received can be varied in such a manner as to provide either long or short "blocks" according to the requirements of the traffic. The experiments described by Herr Bormann were conducted on the military line, 4·34 miles in length, between Mahlow and Marienfelde; and he sums up the results by saying that the apparatus has fully answered all expectations. A train entering a station was warned of an obstacle on the line. Two locomotives approaching each other on the same track were warned. Two trains proceeding in the same direction, the second at greater speed than the first, received warning. Lastly, a train which was entering Mahlow Station received notice that points were in a wrong position. In all these cases the notice was given in ample time to prevent danger, and to render a collision impossible.

The Cost of Electricity on the Canals.—Mr. E. T. Birdsall, in the columns of the New York *Electrical Engineer*, deals with this subject. He submits that from the editorial published in that journal of December 6th, "it would seem that the state engineer, Mr. Martin Schenck, does not take the same view of the problem of propelling canal boats with electricity that the enthusiasts at the trial did. Having gone over the possibilities of this matter some three years ago somewhat thoroughly, I am inclined to endorse his view. At the time mentioned I controlled a water power situated in the Mohawk Valley, only half a mile from the canal and about one-third of the distance from one of its termini. This power has a minimum of 5,000 h.p. at all seasons of the year, and can be developed at a

Digitized by Google

minimum of outlay, yet we could not figure out a saving to the canal boatmen by the use of electric motors in place of the present engines. The enemy of all power transmission schemes is cheap coal, and in this case coal at 2·50dol. and 3·00dol. per ton gave the enterprise its death-blow. I grant that the size of this plant would have been miscroscopic compared with the Niagara power plant, but until reliable figures as to the cost of the power per horse-power at the Falls, and the cost of erection and maintenance of the trolley line on the canal are given, I shall continue to be doubtful as to the commercial success of the plan. I do not question that boats can be propelled by electricity delivered from a pole line, or that they can lessen the time of transit, but the question is, will it pay a divident on the investment? This is the whole problem. Again, is the automobile canal boat the best solution of the problem? I think not. This granted, we have either the locomotive on the towpath or a similar motor placed overhead. The mechanical difficulties of both the latter methods multiply rapidly as we proceed to work out the details of the system, and while I cannot yet see daylight through the problem, I think that either of these plans will give a much lower cost per ton-mile than the one tried. If it is suggested that electric tugs would be a solution of Mr. Schenck's objections, there again comes the question, Would not steam-tugs do the work cheaper? Small compound condensing engines do not use much fuel, and the interest on a pole line the length of the canal will buy a large amount of coal. Unfortunately I did not preserve the data and figures that I made on the cost of electric towing at the time mentioned, as I was certain it could not be made a commercial success at that time. While high pressures and multiphase motors may help the matter some day, yet the difference to be overcome is so great that in the absence of more reliable information and data, I think it will be well to restrain our enthusiasm until we have something more tangible to enthuse over."

Advice to Young Electrical Engineers. — A brief but interesting report of an interview with Mr. L. S. M. Pyke is contained in the December issue of the *University College School Magazine*. The interviewer, "C. L. T. G.," paid a visit to the works in New Tothill-street, first to see and learn what he could about Mr. Pyke's researches, then to find out what the latter thought of the future of high-tension work, and to obtain some advice for those who were thinking of taking up electrical engineering as a profession. "C. L. T. G." was shown over the works, and in reply to a question regarding alternators, Mr. Pyke said: "I have here an alternating-current dynamo whose beauty lies in having but one moving part, and the whole is extremely strong and rigid, and possesses no moving conductors. A large block of wrought iron almost cylindrical, 15in. in diameter and 12in. deep, has a groove turned in it, leaving the centre and a thick outside rim. This is wound so that one pole is north and the other south. Laminated iron projections and bobbins then concentrate the magnetic force in radial lines across the open space. Through the centre of the block a hole is bored which serves as a bearing for the shaft which carries the driving pulley on one side and on the other, iron bars in the shape of an L turned over so that the end turns in and revolves between the coils mentioned and induces alternating currents in them. This machine would light 120 8-c.p. incandescent lamps at the safe and ordinary pressure of 100 volts." Transformers next came under notice, after which the interviewer asked for some advice to the young engineer. To this Mr. Pyke said: "On leaving school I went direct to the works of George Wailes and Co., Euston-road, for I hold that the electrical engineer should have a thorough knowledge of the ordinary mechanical and constructive work—turning, filing, fitting, erecting, etc. It was there that I began my first work in the high-tension line. We had some of Ferranti's earliest alternators to construct, and in the trouble and woe surrounding the first few dozens of these machines it was necessarily possible to gain much experience, at the same time reading and learning all I could in my spare time about the then almost unexplored field which is now my speciality. When I had served my time at Wailes's, I started for myself with my partner, Mr. Harris, in building small dynamos, working a great deal with and for Sir David Salomons, until now our work has so grown that we pay about £50 a week in wages. Electrical engineering is as overcrowded as all other professions, and the man who wishes to make his way must be a hard worker in the first place, and if he has not capital at his back, he must either have a speciality, or must be a genius or something like it."

An Improved Method of Traction Desired.— The Metropolitan Traction Company sent a letter to the New York Board of Railroad Commissioners in November last, offering a prize of £10,000 for the invention of a system of street railway propulsion superior to the cable and the trolley. In this letter the officers of the company say: "On streets where the lines are straight and the business is heavy the cable system is the most economical yet invented. For general use in a city, winding about through the streets following the routes of travel which the public wish to pursue, it is impracticable. You require straight routes for cable roads. We have in addition to the lines upon which the cable will be laid over 80 miles of street railroads now operated with horses, al below the Central Park. It is to these lines in particular that we now desire to direct your attention. Up to the present time the only system whose practicability has been demonstrated is the overhead trolley. We are well aware, however, that its application in the streets of New York would not meet with the approval of the community. What we most desire now is to hasten the development and perfection of a better system. We therefore submit the following proposition: First, we will set aside the sum of 50,000dol. to be awarded as a prize to any person who shall, before March 1, 1894, submit to your honourable Board an actual working system of motive power for street railway cars demonstrated to be superior or equal to the overhead trolley. Second, the qualities necessary to meet this requirement shall be left to your decision; but with the present state of the art, a system to win the award must necessarily approximate the trolley as a standard of economy in operation, but should be without the features objectionable to the public that are in it. Third, we shall exact no rights in the invention in return for the 50,000dol., and shall have nothing whatever to do with the making of the award further than to pay any expenses which your honourable Board may deem it necessary or wise to incur, either in the employment of experts, the giving of hearings, or the conduct of experiments—this in order that no effort may be spared to achieve the desired result." In answer to this proposition, Mr. S. H. Beardsley, on behalf of the Railroad Commissioners, sent a letter to President John D. Crimmins undertaking to co-operate with the company with certain limitations. Mr. John D. Crimmins states that the offer of the company was made for the best interests both of the company and of the city. He was sure the overhead trolley would never be introduced into New York. The general idea was to encourage the invention of some sort of underground trolley system which would be free from the disadvantage of liability to kill horses and men in the streets above it.

A PLEASURABLE NEW YEAR'S VISIT AND DISCOURSE.

Immediately after entering the office of a celebrated firm in Queen Victoria-street a few days ago, I heard a muffled voice exclaim, "A happy New Year to you," and on looking round I beheld a full-sized figure of a jolly Jack Tar standing at "salute." Feeling sure that the good wish emanated from the wax model, I replied, "Same to you old fellow, and to all associated with electric science," and thus commenced an amusing, interesting, and instructive visit. The figure contained a loud-speaking telephone receiver and a well-designed carbon transmitter in communication with similar apparatus in an adjoining room. My next surprise was equally amusing, for after surveying the beautiful display of electric fittings which adorned the showroom, I caught sight of an excellent piano, and was irresistibly tempted to try its musical powers; but judge my surprise when about half-way through that pretty song "You Promised Me," the instrument struck up on its own accord, "Jack's Come Home Again"! The contrast was comical indeed, and as the automatic system (a punctured cardboard band rotated in a drawer under the keyboard by an electric motor) totally eclipsed my feeble attempt at playing, I at once retired to a back seat, pressed an electric cigar-lighter to my "weed," and then listened to some inspiriting tunes as they were evolved by the wily "skeleton in the cupboard."

Frying-pan? Yes, certainly. Just put it on that stand for two minutes; now touch the bottom. I did so, and quickly withdrew my overheated fingers to avoid unpleasant frizzling. "Where is the flame?" I asked. No flame; simply an electric current passing through a wire in the stand. A steak was soon afterwards hissing in the place where my now reddened finger tips had been, and its juicy quality, combined with scrupulous cleanliness, was enough to satisfy a prince and promote the beginning of a life of pleasure for the new year. What with electric kettles, saucepans, tureens, flatirons, curling-tongs, and other heating apparatus, to say nothing of the latest electric novelty (which I was jokingly assured would make a good impression on any uncovered back), a "bacon-marker." I stood amazed at the various contrivances actuated by electricity. Lamps of numerous shapes, ranging in size from a pea (as now used for gun-sighters in the navy) to globes 6in. in diameter capable of yielding 600 c.p.; night-lights for watch stands; arc lamps, some of which were inverted to project the light on the ceiling; all kinds of appliances for theatrical effects; step-up transformers from 100 to 2,000 volts for advertising in Geissler tubes; electric clocks; a variety of models, such as workshops, toy motors, railways, and other essential objects for instructing the young aspirants to electrical engineering pursuits; telephones and shop fittings galore; even electric horse-clippers, helped one and all to make the uninitiated mind more confounded. When we seriously reflect on the advancement of science and its practical applications during the reign of our Most Gracious Queen it seems almost incredible that her subjects could have so fully developed their researches within such a short period. The foregoing details form but a very minute portion of one branch of science, and although much can now be done with electricity and magnetism, yet much more remains to be done. Electricity can produce sound, light, and heat, and, conversely, the three latter agents can generate electricity; but notwithstanding these facts we cannot instantaneously "see by electricity." Some unknown genius may yet, however, accomplish this much-desired end. Following the grand law of conservation of energy we may reason—though not quite true—that an electric lamp reproduces sunlight which illuminated the earth's surface thousands of years ago. For example, trees absorbed heat from the sun and many years afterwards became coal; coal when raised to its proper igniting temperature again liberates the occluded heat; a small proportion of the heat if set free in the fire-box of a steam-boiler enters the water, and then the steam; the steam works an engine and thereby converts a portion of its heat energy into mechanical energy; the engine drives a dynamo, and thus produces electricity; the electricity is suitably conveyed to an electric lamp, where its easy flow is strongly resisted by a carbon filament; this obstruction regenerates heat at a high temperature, and, in consequence, light is again made visible. An old adage says "Wonders will never cease"; but I think the climax will be attained if the bold prophesy comes true—namely, that because electricity can dissolve copper at one end of a wire and precipitate the metal from a blue vitriol solution at the other end of the wire, it may happen, in the distant future, that physicists will be able to decompose a man in London, and by aid of the same current through the Atlantic cable build him up again in New York! P.

ON CERTAIN DEVICES TO UTILISE INDUCTIVE ACTION IN THE CONSTRUCTION OF LONG SUBMARINE CABLES.

BY DESMOND G. FITZ-GERALD.

Considerable interest has been excited, both across the Channel and the other side of the Atlantic, by the statement that the great scientific firm of Siemens and Halske have devised a method whereby they can obtain on a line of which the length is expressed by 3 the same rate of speed in signalling as would ordinarily be obtained on a line of which the length is expressed by 2. In other words, admitting, in accordance with what is known as the law of the inverse square of the distance, that the increase of length from 2 to 3 would ordinarily reduce the speed of signalling to 44·4 per cent. of its original value, they increase the speed of signalling through the given cable just *two and a quarter times*.

If this be correct—and, in the absence of any disclaimer on the part of the eminent firm above mentioned, we may assume it to be the fact—a great step has been made in submarine telegraphy, a splendid achievement in science would appear to have been practically carried into effect. And we may here expect to find consummate skill both in the application of abstract scientific principles and in the mechanical construction of the apparatus, whereby the progress has been realised. In many points of detail—each one essential to success—novelty and originality will no doubt be conspicuous. But, in justice to probably more than one patient worker in the past, we must point out that the device which has been adopted by Messrs. Siemens and Halske, and which is not claimed as new in theory, was not only suggested but was experimentally elaborated to some extent—though not conclusively demonstrated—some 14 years ago. In one particular case, we know that experiments were carried out under many difficulties and discouragements, and that a very high authority was reported to have stated in regard to them that "if the experimenter had been an electrician, he would have known that no increase of speed could be obtained by such means."

The device in question is simply to divide the cable into two or more sections, and at each division to connect the severed portions to earth respectively through the two wires of an induction coil, these two wires being of equal length and resistance, and alternately primary and secondary according to the direction of the transmission.

Supposing the cable to be divided into two, the speed of signalling through each section is theoretically increased fourfold. Assuming the through signals to be strictly consecutive, the signalling capacity of the whole cable would thus be doubled. But in practice no doubt the signals would to some extent overlap—that is to say, signal 2 would be passing through section 1 *before* signal 1 had passed through station 2. On the other hand, the effect of what used to be called electromagnetic resistance, or what is now termed inductance, has to be considered and allowed for. And it should be borne in mind that the electro-dynamic induction effects which are in this case utilised tend to disappear when the inducing current is insufficiently *sudden—i.e.*, when the variable period which precedes its normal passage is unduly prolonged.

Digitized by Google

Analogous to the above device, but containing in far less degree the elements of practicability, is the plan of utilising—or attempting to utilise—electrostatic instead of electro-dynamic induction by connecting the severed portions of the conductor respectively to the two coatings of a condenser insulated from earth. Here the difficulty is encountered of obtaining, by means of two copper bands sufficiently insulated from each other, a condenser of sufficiently considerable capacity as compared with that of the cable itself, which is about one-third of a microfarad per knot. The *inducteous* charge—that of the same sign as the inducing or *inductric* charge—is, so to speak, *lost* in the inductive circuit of the cable, becoming too much reduced in potential to be capable of producing a signal.

The question as to how far the law of the inverse squares of the distances becomes in its effect modified by certain conditions of practice, is—as well as the law itself—of great interest to practical electricians. We look forward to a period when such questions may be studied upon an artificial cable similar to that devised by the late C. F. Varley, but free from the economical makeshifts which had the effect of bringing its artificiality *en evidence*. Such an apparatus would be of national importance, and would probably need to be provided by the nation.

HIGH-SPEED ELECTRIC RAILWAYS.

BY FRANK B. LEA.

When one comes to think of it, the idea of enlarging upon the principles—not to say details—involved in a high-speed electric railway is rather absurd, if not visionary, seeing that the number of lines operated in this country by electric power at any kind of a speed may be reckoned on one's fingers. However, there has been some considerable "talk" upon the subject during the past year; and no less an authority on electric traction than Dr. Edward Hopkinson appears to have regarded the matter as of sufficient importance to merit discussion before distinguished and learned audiences. His treatment of the subject has, of course, been purely general; the absence of practical facts makes it almost impossible to enter in any way upon details, and until railway speeds of 120, 150, or 200 miles per hour can be attained in some fashion, even experimentally or by models, no one ought to predicate the conditions or laws under which such results are to be reached.

Take, for instance, the question of atmospheric resistance, which is dealt with by Dr. Hopkinson in a theoretical manner to show that with a train 200ft. long and travelling at a speed of 200 miles per hour, the energy required to overcome such air resistance alone would be as much as 1,700 h.p. A train of this length may be considered, from the analogy of rolling-stock upon the Liverpool Overhead Railway, to be made up of four cars, each about 50ft. long, and weighing perhaps 60 tons inclusive of motors. A speed of 200 miles per hour is equivalent to one of 17,600ft. per minute, so that on the level, and allowing a traction coefficient of only 10lb. per ton, the power required to maintain this speed with such a train $= \frac{250 \times 10 \times 17{,}600}{33{,}000}$, or over 1,300 h.p. Added to the 1,700 h.p. which Dr. Hopkinson estimates as being necessary to overcome the air resistance, then we have a total of 3,000 h.p. This is equivalent to a total horizontal effort of 5,625lb.; and deducting from this the amount due to traction resistance—viz., 2,500lb.—there remain 3,125lb. as the value of the total air resistance. If this be considered to act wholly in a direction parallel to the line of travel with close-coupled cars having an end area equal to that, say, of the Liverpool Overhead Railway cars—viz., 8ft. 9in. by 11ft. (to rail-level), or, approximately, 96 square feet—the air resistance per square foot of area works out very nearly to 33lb., an extremely high allowance, to judge from the results obtained by Mr. O. T. Crosby a year or two ago, when experimenting upon high speeds and the values of air-resistance coefficients.

"Atmospheric resistance," says Mr. Crosby, "at 150 miles per hour would be taken (in the proposed case) at 15lb. per square foot of cross-section, a wedge or parabolic-shaped head being employed for the car. *This value is 50 per cent. in excess of that indicated by our experiments.* (The italics are mine.—F. B. L.)

Of course, one cannot say that either of these two conflicting *estimates* (for they are nothing more) is correct or incorrect. Actual working will alone show the laws that govern high-speed transit, not only with regard to the atmospheric resistance, but also as to a fair allowance to be made for tonnage coefficient of traction. Of course, the permanent way at such velocities would be of very special character and design; and therefore every care might be taken to reduce the rolling resistance. But even then the allowance of 10lb. per ton might prove too little, although it is well within the mark for speeds of 70 or 80 miles per hour on a first-class track of ordinary construction.

This point brings me to at least one other subject in this connection which is of interest at the moment to those who watch the developments of high-speed transit. I refer to the proposals that have been made with a view to attaining velocities of 150 miles an hour and over, on an elevated single-rail track of the type devised by M. Lartigue, and already used in one or two instances for short local lines at slow speeds.

There seems not to be the least doubt that any such velocities as those mentioned will only be attained by changing altogether the type of roadway adopted; at any rate, the cost of easing curves and grades on a surface line of modern form, in order to run trains at double or treble the present speeds, would be quite prohibitive. In this respect, therefore, the Lartigue system may prove to be the forerunner of a permanent roadway just suitable to high speeds. Personally, I think it goes in the right direction by reducing to some extent the bearing points between trains and rails.

With the powers involved by such high speeds, and the concentration, as it were, of destructive energy along one line, it becomes, however, a matter of supreme importance to increase the strength of the permanent way. I should feel inclined to doubt whether any ordinary girder work on a foundation which is more or less shallow would serve the purpose. The strains in a superstructure of this kind would be enormous, and would necessitate special designs—*e.g.*, each line being adapted for service in one direction only.

This is hardly the place or time to attempt a detailed criticism, however; later on, when actual work is attempted, the particulars may come up for review. At present, therefore, it is enough to say that the scheme, as enunciated, requires considerable modification before it could be put into practice. Take, for instance, the advantage claimed for it of utilising the present railway embankments instead of buying fresh land or rights of way at enormous cost. Surely it is not thought seriously that embankments are to be found along the whole course of our railways! Probably they do not constitute anything like 30 per cent. of the total length of line, and even then would be found to change from embankment to cutting, and *vice versâ*, in a space short enough to prove rather embarrassing to the levels of the single-track system. However, this is a small detail: it is only mentioned to show the necessity of a little wholesome revision on certain points. Generally speaking, the system has decidedly interesting and useful features.

STANDARD CELLS.

BY E. C. RIMINGTON.

It is, I think, not generally known that a Clark standard cell is perfectly unharmed by being circuited through resistances of the order of 1,000 ohms. Some years ago the writer made a long series of experiments with various patterns of this cell, employing a variety of different pastes, etc., and, among others, tried the rate of recovery from polarisation due to circuiting. Two identical cells, made according to Lord Rayleigh's instructions, in test-tubes about ¾in. in diameter, were used, the ratio between their E.M.F.'s compared, and was found to be 1·00027. The

Digitized by Google

cell of higher E.M.F. was then circuited through 1,000 ohms for 17 minutes. It internal resistance was afterwards measured by Mance's method, and found to be about 130 ohms, so that the total resistance of the circuit was 1,130 ohms, and the current given about 1·27 milliamperes. The circuit was then broken, and its rate of recovery noted by comparing its E.M.F. at definite intervals with that of the other cell. The second column in the subjoined table gives the ratio of the E.M.F. of the cell that has been circuited to that of the uncircuited one.

Time reckoned from instant of breaking circuit.	Ratio of E.M.F.'s
2½ minutes	·9999
4 ,,	1·00007
9 ,,	1·00020
31 ,,	1·00021
1 hour 20 ,,	1·00027

So that in one hour twenty minutes it has completely recovered, while in nine minutes its recovery is enough for all practical purposes.

In the above cell the surface of mercury would be about ·44 square inch; as a matter of fact it was less than this, as a glass tube containing the platinum wire dipped into it, and this would reduce it to about ·4 square inch. This gives a current density of about 3·2 milliamperes per square inch of mercury surface. A larger cell would, of course, have a greater surface of mercury, and would bear circuiting through a lower resistance for the same amount of polarisation.

THE EXPENSE OF RUNNING ELECTRICAL ENGINEERING BUSINESSES.

BY SYDNEY F. WALKER.

Probably few electrical engineers, except those who have been in business for a number of years, appreciate how very heavily all electrical engineering work is handicapped by the dead expenses involved in carrying on the work. The remark is true of all engineering businesses, but particularly of electrical engineering. Even the rapid advances of which all electrical engineers are so proud, add considerably to the cost of working. Some new improvement is made, and not only patterns and drawings, but perhaps a lot of finished work becomes dead stock, of the value of old metal. When, too, as is constantly happening, one firm works out an improvement in some part of their apparatus, every other firm making the same class of apparatus must follow suit, no matter at what cost, or be left out in the cold when orders are given out.

It must be borne in mind too, by those who think electrical engineering businesses so many veritable Eldorados, returning enormous profits upon small outlay, that the proprietors of an electrical engineering business have to make good, not only their own slips, but those of all their employés, and often those of the employés of other firms. To be successful, you must follow your work, see it kept right, no matter what it costs or into whose hands it goes. If you do not, any breakdown is attributed, not to the apparatus being improperly looked after, but to the apparatus itself being improperly made. And unfortunately, too, electrical engineers are very much like women, in that they are rarely able to see any good in each other's work. Few electrical engineers, if called in to repair the work of another firm, can resist the temptation to condemn the rival firm's work. And so all these little things cost money, and a good deal of it. And besides all these, as every electrical engineer of experience knows, every now and then something turns up, some new development of the laws of the science that had not occurred to anyone before, that often appears at first sight to be contrary to those laws, but which always lead to one result—additional expense, more or less heavy, for the manufacturer or contractor.

And the above are in addition to the regular expenses of all properly conducted businesses. Keeping accounts so that you may know what you are owed, and what you owe, and what your expenses really are, is an important and often a very heavy item in proportion to the business done. Even the correspondence of electrical engineers in business is heavier and more costly than that of other businesses. The thing is new, and buyers often require to be very sure of their ground. Misunderstandings are more likely to arise over work that is quite new to one of the parties concerned than where both are familiar with the principal details. And this necessitates the treasuring up of every letter that one has written or received for years after.

Securing orders is also, if one may judge by what one sees in other lines of business, a far more expensive matter in electrical engineering than elsewhere. Electrical engineers themselves are, perhaps, to blame for a large part of this. No sooner is it known that an order is in the market than the representatives of several firms rush for it, each bent on belittling all his rivals. Tenders, too, are a constant source of expense, and the writer believes affect electrical engineers more severely than other business. People do not scruple, apparently, on the plea of asking for a tender, to put several firms to heavy expense often without the slightest intention of employing any of them; sometimes even merely with a view to obtaining information.

All of these things, and many others, cost money, and, unfortunately, the sum of them, when added up, bears a very heavy proportion to the amount of business done. With limited companies the proportion is usually even higher.

The writer's object in penning this article is to endeavour to deter those who are engaged in electrical engineering businesses from the stupid practice of cutting prices. If your business is to continue, and if you are to make a moderate profit out of your business, you must have a certain average rate of profit on your transactions, such that the sum it furnishes in the year will cover your expenses and leave you your modest profit. If you attempt to cut below this figure, whatever it may be, you will lose money and your business. If you attempt to cut your coat to your cloth, or, in other words, to make a profit by inferior work or materials, you will lose your business as soon as the results of your work have had time to show themselves. If you simply take the loss, carrying out the work as it should be done, you will lose your capital.

If anyone will look round at the firms that are now in existence that were in existence 10 or 20 years ago, he will find two characteristics invariably present. The work of these firms has been invariably good, and their prices have been high in comparison with those of other firms since deceased. These firms—those that are still standing—have marched well abreast of the times. Research and practical work have always gone together, and the research has been paid for, as it should be, out of the profits made on the practical work—that is to say, by the purchaser, for whose benefit the research was undertaken.

Young engineers, too, often fancy that they have a heaven-born genius for conducting business. No special knowledge is supposed to be required, no training, for what is perhaps the most difficult work that one can put one's hand to. Often the youngster thinks he will make up for the want of experience, both in business and in engineering, by the exercise of the very worst quality that a business man could be cursed with—that quality of sharpness, of over-reaching, that so many mistake for the necessary business quality of shrewdness—forethought. There is no necessity for any young electrical engineer who knows his work to go into business for himself. There are plenty of openings for properly trained engineers. An electrical engineer has only to master his work, as far as it is known, to strike a line for himself, and to go on working away as hard as head and body will let him, continuously, and he will be bound to succeed in the end. This success, too, will come at a time when he will most appreciate it, when Nature begins to warn him that the pace must not be so rapid, and in consequence of his success it need not be so rapid. If he goes into business and does not succeed—and few can—he will find himself thrown out of the race, and that many whose abilities were not equal to his have passed him; just as the hare found when he raced with the tortoise. We are apt not to look upon the tortoise as an animal to be admired, nor as one whose ways we should emulate, yet the way of the tortoise in the fable is the way to success in electrical engineering. Strike a bee line, as the Americans would say, and keep on pegging away.

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

(All rights reserved.)

(Continued from page 559, Vol. XII.)

TRANSFORMERS.

From what has been stated regarding the features of high and low pressure distribution, it is at once apparent that the best way to distribute electric power over large areas with a limited loss, and also at the same time to introduce it into the consumer's premises at a low and safe voltage, is by using a combination of pressures, a high pressure being used for "distributing" purposes, and a low pressure being used on the "lamp" circuits. This can be effected in alternate-current work by the aid of what are named "transformers," and their object is to transform or convert small currents of high voltage into large currents of low voltage, and *vice versâ*; so that the electricity is sent out into the distributing mains at a high pressure, and where a tapping is made for a consumer, a transformer is connected up to the primary circuit to receive the high-pressure current while it gives out a low-pressure current, which is led into the secondary circuit, the current being thus transformed. A transformer which changes a current from a low pressure into a high pressure is termed a "step-up" transformer, and a transformer which changes a current from a high pressure into a low pressure is termed a "step-down" transformer.

Except for a small loss, the power received and the power given out are the same, so that when the pressure is decreased the current is increased; for example, a high-pressure current of 20 amperes at 2,000 volts is led into a "step-down" transformer, and if the winding on the core is such that the pressure is decreased to 200 volts then the current will be increased to 200 amperes, because $2{,}000 \times 20 = 200 \times 200 =$ watts. In its simplest form a transformer takes the form of an annular ring of iron, having a great number of turns of thin wire wound on one side and a small number of turns of coarse or thick wire wound on the opposite side—the thin wire is named the "primary" coil, and the thick wire the "secondary." The high-pressure current being led through the primary coil induces a low-pressure current in the secondary, or a low-pressure current being led through the secondary will induce a high-pressure current in the primary. These two windings are entirely distinct from each other, and well insulated from one another. Instead of the two windings being on opposite sides of the ring, one can be wound on the top of the other, in which case it is usual to wind the primary on first, the secondary being wound on top of the primary. Fig. 39 shows a ring with the primary and secondary on opposite sides, A representing the primary and B the secondary.

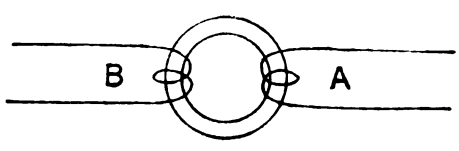

FIG. 39.

It is thus seen that an alternate-current transformer consists simply of copper and iron—copper to carry the electric current, and iron to carry the magnetic flux. The ratio between copper and iron for transformer design is a very nice point. As yet there does not seem to be sufficient practical data to warrant any decided ratio, and, in addition, this ratio would not be the same for all kinds of transformers: it would vary with the nature of the design, and also with the requirements of the transformer. Some design for high efficiency at heavy loads, others strive to produce one that will possess a high efficiency for low loads; others, again, prefer to design one that will give the best average efficiency for all loads. To give an idea, it may be assumed that a fair ratio between copper and iron is 1 : 2, and that 1lb. of copper and 2lb. of iron, or total of 3lb., will yield an output of 60 watts, or sufficient energy for one incandescent lamp of 16 c.p. This is at the rate of 20 watts per pound dead-weight, and applicable to a medium-sized transformer; one that would run, say, 100 incandescent lamps of 16 c.p., and thus have a total weight of 300lb.

It is necessary to fix transformers in a fireproof place, since they heat up very much when at work, the iron core becoming hot through "hysteresis" effects of the alternating current. This heating signifies so much loss of energy, and the greater this loss the less is the efficiency of the machine. The best modern transformers will now give an "efficiency" of between 96 and 97 per cent. at full load, and 94 per cent. at one quarter load. These figures are very satisfactory, and there does not seem to be much room for improvement as regards their efficiency at full load and half load. It is only when they are worked at light load that they become terribly wasteful, unless they are designed especially for light loads, and in that case they are not efficient with heavy loads. What is wanted is a transformer that will give a good efficiency for all loads, from full load down to a few lamps. The iron core of the transformer is always laminated, or built up, by using a number of thin sheets, as is the case in the construction of all alternate-current apparatus that contains iron, each sheet being insulated from the other by shellac, paper, etc., or some such suitable insulating material.

In high-tension alternating-current systems of distribution it is the present practice to "bank" transformers. By "banking" is meant grouping together in sub-stations. Thus there are two networks of distributing mains—(1) the high-pressure primary mains that ramify from the generating source, and (2) the low-pressure secondary mains that branch out from several determined centres, positioned at suitable places throughout the area to be supplied; it is at these centres where the sub-stations are built, each having a number of transformers, some large and some small. As the load increases, so transformers are switched into circuit, and as the load decreases they are switched out; hence it is necessary to have an attendant at each sub-station to watch the load and perform the above operations. By this device, no transformer need be at work with a light load, and by the aid of one or two small ones, to put in circuit when the load will not justify the employment of a large one, the losses are reduced considerably. It may be remarked that the core losses, or the loss of energy due to the heating of the iron, is almost independent of the load, and so when the load is light, they form much the greater part of the total loss of energy in the transformer. To protect the primary and secondary windings from an undue current, suitable fuses are inserted in the terminal-box of the transformer, a fine fuse being used for the primary and a thick one for the secondary. It is usual also, in some cases, to have the secondary coils wound in two windings, so that by the aid of a connecting strip in the terminal-box, the secondary can be at once connected up either in parallel or in series. In the former case the voltage may be, say, 50 volts, and in the latter case it would then be 100 volts, the transformer being applicable to either of the two pressures. It is not often in practice that the primary fuse "blows"; if it does, care should be taken that the primary coil be cut out of the high-pressure circuit before an attempt is made to replace the fuse. The secondary fuse is much more liable to blow, as it is direct on the lamp circuit.

Sub-stations are expensive places to build and equip with apparatus, and, in addition, the necessity of having attendants in charge makes their proper maintenance still more expensive; so that the presence of the transformer in alternate-current distribution materially reduces the saving that is gained by the employment of small conductors. Some go so far as to say that the cost of transformers comes to more than the saving that is effected in the cost of copper by employing small conductors for high-pressure currents, and however true this may be for limited areas, there seems to be no mistake about the fact that for large and extensive areas high-pressure alternating currents are preferable to three or five wire direct currents, in order to obtain a distribution of power in an economical manner and, above above all, with effective and good regulation for constant lamp pressure.

METHOD OF SUPPLY.

BY G. OFFOR.

Managers of electric supply works have always two "prominent topics" to trouble them: (1) regularity and economy of supply; (2) how to increase the number of customers.

Upon the first point I have had, perhaps, less anxiety than many of my *confrères*, as the companies with which I have been connected having adopted the storage system of supply, it has never been my experience to deal with failure of the light through accidental stoppage of the generating machinery; but indirectly I have been affected by irregularities elsewhere, which have occasioned uneasiness as to the general character of electric supply.

Take the following conversation as an illustration: Speaking to a resident of Sydenham about his adopting the electric light, he remarked:

"I am afraid of it, for it is so uncertain. During my autumn holiday at the seaside, the electric light there was constantly going out, and while dining at South Kensington a short ago we were suddenly in darkness in the middle of our dinner."

"But such a thing could not happen in Sydenham under our system of storage," I replied.

"Oh," said he, "I cannot go into the question of 'system.' I know nothing about that, and until I am sure that you electric engineers have adopted a universal system of constant supply, like the gas companies, I shall hold off from spending money on wiring and fitting my house."

Another resident instanced the supply at two towns he had visited, where the electricity was only supplied during part of the 24 hours, so that if sudden darkness came on during the morning, or a lamp were wanted in the middle of the night, there was no light available.

These imperfect systems of supply no doubt create prejudices which cause an unfavourable public opinion, even in localities like Sydenham and Upper Norwood, Notting Hill, Chelsea, Oxford, etc., where electricity is supplied throughout the 24 hours continuously and with regularity by the aid of storage batteries. Economy of supply is, of course, of the utmost importance, but efficiency is still more essential; the most perfect system is the first consideration, and until this is universally accepted the difficulties I have alluded to will remain to vex the supply companies. But is it quite clear that the least effective systems are the most economical?

I suppose that all will admit that a supply based on a reserve of stored electricity is theoretically more perfect than absolute dependence upon the moving machinery. As in the case of gas, it is obviously more perfect to deliver from gasometers than direct from the retorts.

Assuming, then, that a continuous current with storage reserves is the most perfect system, it has been argued that for scattered districts the high-pressure alternating-current system is most suitable, owing to the economy and ease with which it can be distributed and converted at sub-stations or on the owner's premises into low pressure; but by the aid of motor-dynamos and accumulators the high-pressure continuous current can also be distributed economically over large and scattered districts, with the special advantage of the storage reserve and the running of the machinery always at full loads.

Upon the second point, all the supply companies experience the same difficulty in increasing the number of customers—viz., by the deterring effect of the first cost of installing the light. When the occupiers are also owners of property the question is a simple one, but with short tenancies there is a great hesitation in spending money in improving other people's property. To some extent the obvious advantages of the electric light induce people to incur the expense, whether owners or only occupiers; but if some equitable system were introduced under which the cost of wiring and fitting was defrayed by deferred payments, or undertaken by the supply companies on a similar hire system to that adopted in the loan of gas stoves by the gas companies, a very large addition to the customers would immediately take place.

WHERE IS OUR TELEGRAPHIC PROGRESS?

There is a strange absence of stir and advancement in the telegraph world. 1893 has been absolutely barren of anything to show that the United Kingdom holds its own at the head of inventive originality and progress in connection with the applications of electricity and mechanics to this one of the most useful of arts. Years have passed since the late Sir Francis Bolton, and later on Major Law, worked at multiple type-setting telegraphs for Press work; and yet, although from time to time we hear of some new start having been made in that direction, nothing worthy of being followed up by practical telegraphists is forthcoming. It is quite possible that the low cost of Press rates, introduced in 1870 by Mr. Scudamore, very much as a sop to conciliate the Press and secure their support to his great Telegraph Bill, has been the cause of want of stimulus to enterprise in that direction. If the use of a wire for Press work, costing the newspaper proprietors about one-tenth of what is charged for private work, was not so recklessly cheap, there can be little doubt that we should ere this have had many minds directed towards the combination and practical development of the beautiful mechanisms which have already been produced for transmission and simultaneous type-setting of news messages in large quantities and at high rates of speed. As to the Press telegram question generally, there is little doubt we should but for the occupation of the wires during the time outside the busy hours of the day with unprofitable (from a revenue point of view) news work, have long ago had the question of cheap "deferred," or "second-class," messages gone into by the postal telegraph authorities. The fact that this system was brought forward in a practical way by Major (now Major-General) Webber, R.E., in the seventies, as a witness before Dr. (now Lord) Playfair's Telegraph Committee of the House of Commons, and recommended by them, would seem to have given it a blow from which it has never recovered. But the unearned increment lying hid under the application of such a principle might bring joy to the heart of the present Chancellor of the Exchequer, if he would try and understand it, and let himself be advised by others than those pledged by their former adverse reports to find no good thing in it.

M.

CRANES AND CRABS.

Let not the gentle reader imagine that the above title implies a desire on the part of the *Electrical Engineer* to follow—*longo intervallo*—the lead of an enterprising and largely-sold monthly magazine, whose "Zig-Zags at the Zoo" are as popular a feature as any in the index of contents.

The appliances to be dealt with in this article are wholly inanimate, although their names may be due to the birds and crustacea whose characteristics they to some extent were evidently supposed to resemble, when first devised and named. It is, at any rate, interesting to see how the long neck of the bird "crane" is reproduced in the fixed or swinging jib of an inanimate iron crane; and how the sideways crawl of a crab may be noted in the traverse motion of any overhead travelling crane.

Putting philology aside, some brief consideration may first be given to the principal features of hoisting appliances in general, before proceeding to look into the question of operating these by means of electricity. It will be found on examining the subject that the "winch" or geared barrel forms the base of nearly all hoisting appliances; and, for the present purpose, this may be considered absolutely the case. It is so, at any rate, in all cranes for which electric power is likely to be employed, whilst the crab—which forms so essential a feature of overhead travellers—is practically nothing but a winch on wheels.

Of course, the main purpose of cranes of all sorts is the transference of goods or heavy articles from one place to

Digitized by Google

another; and therefore the fundamental distinction between the different types may be considered to depend upon the ability of the hoisting apparatus to move bodily with the load or not. That is, roughly speaking, all cranes may be divided into two classes—locomotive and stationary. The latter would, of course, include jib or swing cranes, movable round a pivot, such as are in common use on board ship for unloading cargo, on quays, in warehouses, foundries, and workshops; whilst the former class, almost equally large, embraces cranes from railway breakdown appliances to overhead travellers, or the Titans employed on wharves and piers.

Each class, thus broadly indicated, contains a very large and varied assortment of types, and obviously, therefore, a complete description of these would take up too much time and space. A few only of the leading forms may with advantage be dealt with in order to show how far they have proved suitable for electrical working.

With regard to the class of fixed cranes, there seems to be no great economy promised from the use of electric power; in most cases the hoisting operations are carried on at intervals only, so that for small weights hand labour (with cheaper and simpler crane mechanism) serves every purpose; whilst heavy loads are lifted, as a rule, by steam power (also involving cheaper and perhaps less complex apparatus than in the case of electrical working).

Locomotive cranes, however, seem to offer a peculiarly suitable field for the employment of electric power, owing to the ease and economy with which the supply of electric energy is maintained from a source otherwise useful, say, for lighting purposes.

Any general criticism of one system as opposed to another—*e.g.*, steam or hydraulic power *v.* electricity—need, however, hardly be entered upon at this point, if at all; circumstances alter cases so much that a real comparison is by no means easily made, although efforts (more especially of late) have been put forward to reach a quantitative relation of economy between the three chief systems.

The cleanliness, ease of application, and average economy of electric working will always prove powerful factors in securing its adoption; this has already been proved by extensive use, more especially with overhead travelling cranes. We may therefore confine our attention to the latter for the present. Of course, the mechanical design and features of such appliances are practically the same as when steam applied direct, endless rope, square shaft, or other method is employed—that is, the general dimensions and speeds remain the same, even though the motive or actuating power may vary.

As instances of such may be taken the following, which are leading dimensions and particulars of a set of four electric overhead travellers recently built and installed for a locomotive works in the United States:

Building.	Maximum weight lifted.	Span.	Distance of travel longitudinally.	Speed, travel per min. Longitudinal.	Transverse.	Hoisting.
Erecting shop	40 tons	80ft.	500ft.	125-250ft.	100ft.	5-18ft.
Machine shop	10 tons	62ft.	350ft.	200ft.	100ft.	7-21ft.
Foundry	12 tons	50ft.	,,	,,	,,	,,
Boiler shop ...	20 tons	60ft.	—	,,	,,	6-12ft

It is curious, by the way, to note how extensive has been the application of electric cranes to locomotive shops, not only in the United States, but also in this country and on the Continent. The reason is obvious: very heavy weights—especially in the erecting shops—require lifting, and considerable power must therefore be exerted. The use of steam would prove costly and inconvenient: flying ropes have hitherto been preferred, but the constant waste of power involved by keeping these always in motion at high speeds proves also a serious objection. Now that so many works are being lighted by means of electricity it has become a matter of great ease to employ part of the current for operating the cranes; and thus all waste of power is avoided, as well as the care and attention required to keep in fair order the ropes and pulleys—always a source of dirt, and sometimes one of danger.

At the Crewe works of the London and North-Western Railway considerable use is now made of electric cranes their cleanliness and economy of working have given great satisfaction. Of those at work so far, the largest has a lifting power of 10 tons, and is operated (similarly to the others) by three distinct electric motors—one for each motion: lengthways, across, and lifting. This is a characteristic to which special attention may be directed, and later on the point will be discussed more fully.

The motors, which were made in the electrical department at Crewe works, are of the well-known "Manchester" type, with ring armatures running at 2,000 revolutions per minute. On each motor spindle is mounted a worm gearing into a worm wheel, so as to reduce the speeds. The cross traverse is thus worked at a speed of about 50ft. per minute, and the longitudinal about twice as fast. As a contrast to this type of crane may be mentioned one of nearly equal power now being completed by Messrs. J. G. Statter and Co., Limited, for the East and West India Docks. This is capable of lifting three tons at a speed of 20ft. per minute, or six tons at half that speed; the cross traverse of crab is made at a maximum of 60ft. per minute, and the longitudinal traverse at 80ft. per minute. A single electric motor is employed; it runs at 850 revolutions per minute, and drives the first motion shaft at 192 revolutions per minute by means of link belting of a section shaped to the rim of the pulley. A jockey pulley on the slack or under side of the belt, with double flanges, serves to tighten the belt as required to take up wear and stretch, and also helps to keep it on the pulleys in case of quickly-applied strains.

From the countershaft the motion is transferred to the three shafts operating the traverse and hoisting gears by means of friction cones. The difficulty sometimes experienced with gear clutches is therefore avoided.

(*To be continued.*)

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

SHUNTS.

SIR,—According to your contemporary *Lightning*, I have backed "H. L." in the matter of shunts, and I am further accredited with unassumed ignorance on the ground that I have criticised Kempe without understanding him. I am not, however, conscious of having backed "H. L." or affronted Kempe further than this—*i.e.*, that "H. L." is undoubtedly right in his contention that text-books tell us shunts *divert* current, and Kempe is undoubtedly wrong, as he falls into the same error. But I must admit, Sir, my ignorance and plead guilty to the charge brought against me by *Lightning*—which, however, I take it, is not forked, but a harmless form of discharge giving out light for too brief a period to have any practical value for good or ill. Your contemporary says: "His whole difficulties arise from the fact that, when Kempe is speaking of the E.M.F. in the circuit, 'Sidelight' understands him to mean that across the terminals of the galvanometer." This, Sir, reminds me of Mark Twain's account of his first interview with Bret Harte after, as no doubt you will remember, an early whisky cocktail, and my confusion is in no way inferior to his. If the E.M.F. in the circuit is not the E.M.F. across the terminals of the galvanometer, I have completely misunderstood "H. L.," and my remarks, like the galvanometer, must appear to be disconnected. Possibly the festive season is introducing a factor in our controversy, and a new reading of Ohm's law—*i.e.*, $\text{Clearness} = \frac{\text{Education}}{\text{Riotous living}}$—may explain the cross-purposes at which we now find ourselves. The main question at issue seems to me to be whether or not shunts *divert* or *split* current, and perhaps if we (I refer to your contemporary and myself) shunt cocktails for a week, and so divert the potentiality of our desire to split the harmony of—but, there, I'll say no more.—Yours, etc.,

January 3. SIDELIGHT.

Digitized by Google

SHUNTS.

SIR,—I am writing the continuation of my letter in yours of December 29, within a few short hours of seeing that none too modest lucubration in print. I am ashamed of it; and yet the "of course" was enough to madden a sane man. It is the lip service of egotism; and when a man asks for bread and gets stones, he is naturally a little bit ruffled. I started fault-finding with definitions and explanations as given in the ordinary books, and am met with a snivelling "of course"; and having probably spent more hours than this critic has spent seconds in consideration of the subject, I am justified in resenting the sneer, "of course." But no more of this writer. Let me get to other grounds. "Sidelight" refers me to Kempe, an authority to whom all of us owe a debt of gratitude for his excellent work on testing. More power to his elbow! Yet Kempe, so far as I recollect him, or can see from another hasty glance at his fourth edition, fails in the particular I want. Examine Chapter IV.—on shunts. You will find it commences to discuss the proportions of the current which go through the shunt and galvanometer respectively, the multiplying power of the shunt and compensating resistances; then we come to joint resistances, and an examination as to the value of certain shunts and compensating resistances, etc. I do not find a single reference to the "of course"—pardon me, it slipped out unawares. I mean to say, there is no reference to diminution of acting pressure. Further examine the example on pp. 83-4, par. 82, entitled "The Equal Deflection Method."

"*Equal Deflection Method.*—The theory of this method is as follows: the galvanometer whose resistance, G, is required, a resistance, ρ, and a battery, E, of very low

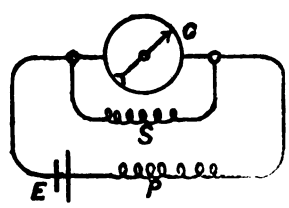

FIG. 37.

resistance, are joined up in circuit, as shown by Fig. 37, a shunt, S, being between the terminals of the galvanometer; a deflection of the galvanometer needle is produced. Let C be the current flowing out of the battery, then

$$C = \frac{E}{\rho + \frac{G S}{G + S}}.$$

This current divides into two parts—one part going through S, and the other part through the galvanometer. It does this in the inverse proportion of the resistance of those circuits; the part C_1 going through the galvanometer being

$$C_1 = \frac{E}{\rho + \frac{G S}{G + S}} \times \frac{S}{G + S} = \frac{E S}{S (G + \rho) + G \rho}.$$

"The shunt, S, is now removed; this causes the deflection of the galvanometer needle to be increased. ρ is now increased to R, so that the deflection becomes the same as it was previous to the removal of the shunt; or, in other words, so that the strength of the current passing through the galvanometer is C_1, then

$$C_1 = \frac{E}{R + G};$$

therefore

$$\frac{E S}{S (G + \rho) + G \rho} = \frac{E}{R + G}.$$

By dividing both sides by E and multiplying up, we get

$$S R + G S = G S + S \rho + G \rho;$$

therefore

$$G \rho = S R - S \rho,$$

from which

$$G = S \frac{R - \rho}{\rho}."$$

I find in these formulæ the symbol E, and ask my "of course" critic (it has slipped out again) if E in these formulæ has a variable value, or rather, if Kempe or any other author explains that it has a variable value. Perhaps I shall be told that, for simplicity's sake, writers *assume* E to be constant, while they, "of course," know it is variable. If that is so, am I not justified in calling attention to inaccuracies in the books ordinarily used, and seeking to find one which shall give me a full explanation of the subject? I am certainly not anxious to show my own ignorance, but I mean to find out where I or the books are wrong. Consider the case diagrammatically:

First.—Let A B represent an homogeneous conductor resistance, and A C the total pressure of the battery. Suppose, in the first instance, the battery to be a large secondary with many cells in parallel, so that internal resistance may fairly be neglected.

Join C B.

Then C B will represent the fall of pressure through the circuit. This fall is regular, and a perpendicular upon A B, touching C B, will show the pressure acting at that point in the circuit. Let E F be such a perpendicular at any point, E. Then E F represents the acting pressure at E, and if from F we draw F G parallel to A B, cutting A C in G, then G C shows the loss of pressure over that part of the circuit indicated by A E.

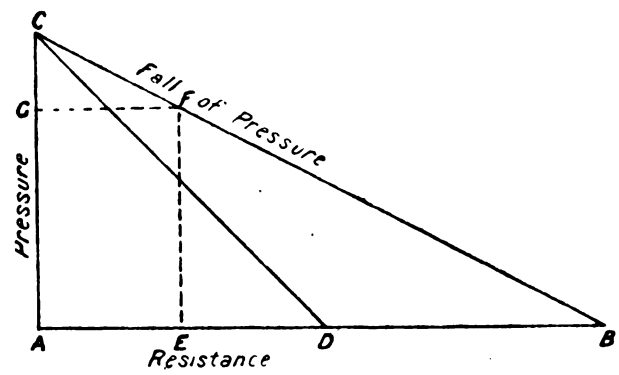

Fig 1

Suppose A B represent the galvanometer resistance.

Now put in a shunt of similar conductor and equal resistance. The total resistance of the circuit will be halved, and may be represented by A D = ½ A B.

Join C D.

In the new circuit, C D represents the fall of pressure.

By Ohm's law, current = $\frac{\text{pressure}}{\text{resistance}}$.

Let C, E, and R represent respectively current, pressure, and resistance.

In the first case $C = \frac{E}{R} = \frac{A C}{A B}$,

In the second case $C_1 = \frac{A C}{A D} = \frac{A C}{\frac{1}{2} A B}$,

whence it will be seen $C_1 = 2 C$, or current is doubled; equal parts going through shunt and galvanometer—*i.e.*, by the insertion of the shunt, no change at all has been made as to current through the galvanometer. Am I so far correct?

Secondly.—Now let us take a case where internal resistance may not be neglected, and where there are other resistances besides the galvanometer and shunt.

Let A C represent the total pressure of battery.

Let A D represent the internal resistance of battery.

Let D B represent the external homogeneous conductor resistance of circuit.

Join C B.

Then C B may represent the fall of pressure through the circuit. From D draw D E perpendicular to A B, cutting C B in E. Then D E represents the pressure acting on the external circuit, and A C − D E = loss of pressure to overcome internal resistance. Take any point

Digitized by Google

F in the external circuit. Draw F H parallel to D E. Then F H indicates the pressure acting at the point F, and D E – F H represents the loss of pressure required to overcome the resistance D F. Similarly, G N represents pressure acting at G.

From E, H, N respectively draw lines parallel to A B, cutting A C in R, P, Q respectively,

Then C R represents pressure used up by resistance A D.
R P " " " " D F.
P Q " " " " F G.
Q A " " " " G B.

Now is it true that so long as the resistances A D, D F are constant, so long will they use up pressure indicated by C R, R P, or the total C P, leaving F H or A P acting at F?

Suppose F to indicate one terminal of a galvanometer and G the other terminal.

We require pressure A Q to overcome resistance G B; so we have pressure, indicated by P Q = H O, acting on the galvanometer. The pressure, resistance, and fall of pressure, so far as the galvanometer is concerned, may be represented by H O N; where H O is the acting pressure, O N the resistance of the galvanometer, and H N the fall through the galvanometer circuit.

We have seen (Case 1) that insertion of an equal and similar resistance to the galvanometer merely causes a more rapid drop in the pressure with a corresponding increase of current.

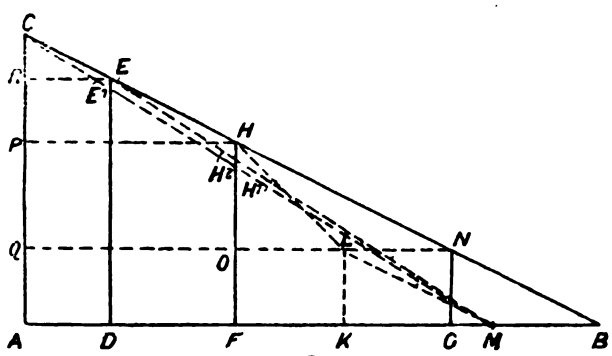

Fig. 2.

Insert such a shunt between F G. This reduces the resistance between the points F G to one-half what it was before. Let the new resistance be indicated by F K or O L.

Join H L.

Then under the new conditions, H L shows the fall of pressure. Through L draw L M parallel to N B, meeting A B in M.

Then L M indicates, as does N B, the fall of pressure due to resistance, K M = G B.

A M may be taken to represent the total resistance of the whole circuit after insertion of shunt.

Join C M, and taking the circuit as a whole, will C M show the fall of potential? If it does, we at once see that the pressures acting at the points, D, F, have lessened to D E_1 and F H_1.

But at the outset I shall probably be told, with good reason, that this is wrong, and that I should join E M, not C M; and in this case, if the argument be right, F H_2, not F H_1, is the acting pressure after the shunt is inserted.

Will some kind reader tell me am I so far correct?

Thirdly.—May we not take it that the total pressure of the battery has nothing to do with the difficulty, and that of this total pressure a constant part is absorbed by internal resistance without being affected by changes in the external resistance. So for all practical purposes of the kind discussed, all we have to consider is the pressure acting on external circuit which is a constant. I cannot for a moment see why, under any variations in the external circuit, there should be a different fall of pressure due to internal work. If I am wrong, I want to know it! Assuming I am correct, then

D E, Fig. 2, or Fig. 3, is constant.

Let D B, Fig. 3, represent the resistance of galvanometer, with no other external resistance, such as D F, G B, Fig. 2.

Can any shunting of D B interfere with current in D B, and if so, how? If the shunt be of equal resistance to the galvanometer, then D K = ½ B D represents resistance, and the current is doubled, the second half of current going through the shunt with no change in the galvanometer.

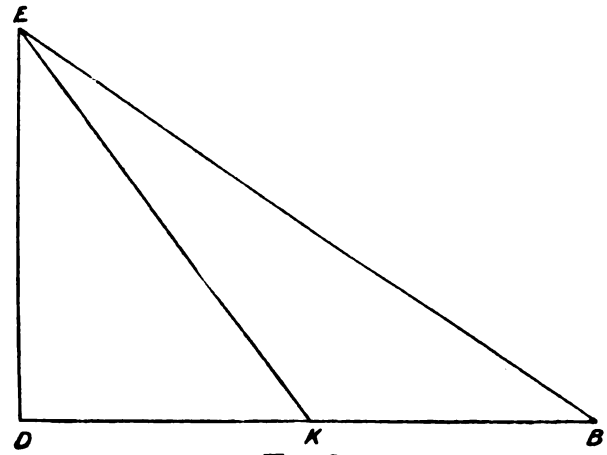

Fig. 3.

Now, Sir, your obtuse "of course" friend, I should say wilfully mistook what you said—as he must have wilfully quoted another contemporary in the same issue instead of you. Indeed, to the outsider this seeming wilful misrepresentation is puzzling to account for. "Of Course" has a chance to explain everything. You have not done much towards explanation except to agree that with "pressure constant," shunts won't affect the original circuit. So far as my reading goes, no book tells me how to get the new pressure if pressure is variable. Is it something like $\frac{D\,E}{D\,M}$ tan E M D? Fig. 2.

Fourthly.—Actually, are we not taught by our books to do something like this?

In Fig. 4, let D E = acting pressure;
D K = resistance of shunted galvanometer;
K B = resistance of compensating resistance.

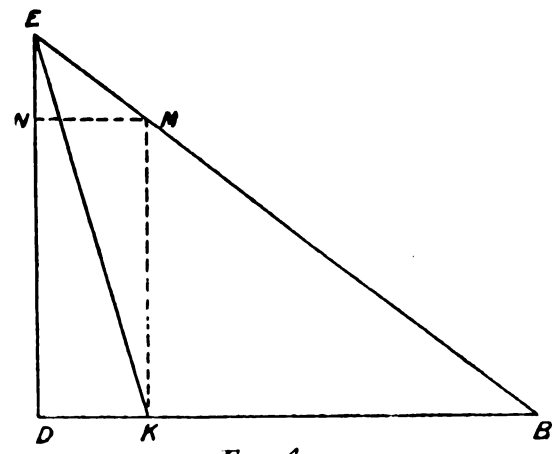

Fig 4

With shunted galvanometer alone, E K represents fall of pressure. With shunted galvanometer and compensating resistance, E B represents fall of pressure, and here E M represents fall of pressure through shunted galvanometer part of circuit, and E N shows acting pressure through galvanometer circuit.

Once more, Sir, I would like to know where to find all about these things. I started cussing books and teachers for wasted money and time—and thank Mr. Walker and "Sidelight" for their contributions to help me; but perhaps I have at last shown the maze into which I have fallen. Who will help me out?—Yours, etc., H. L.

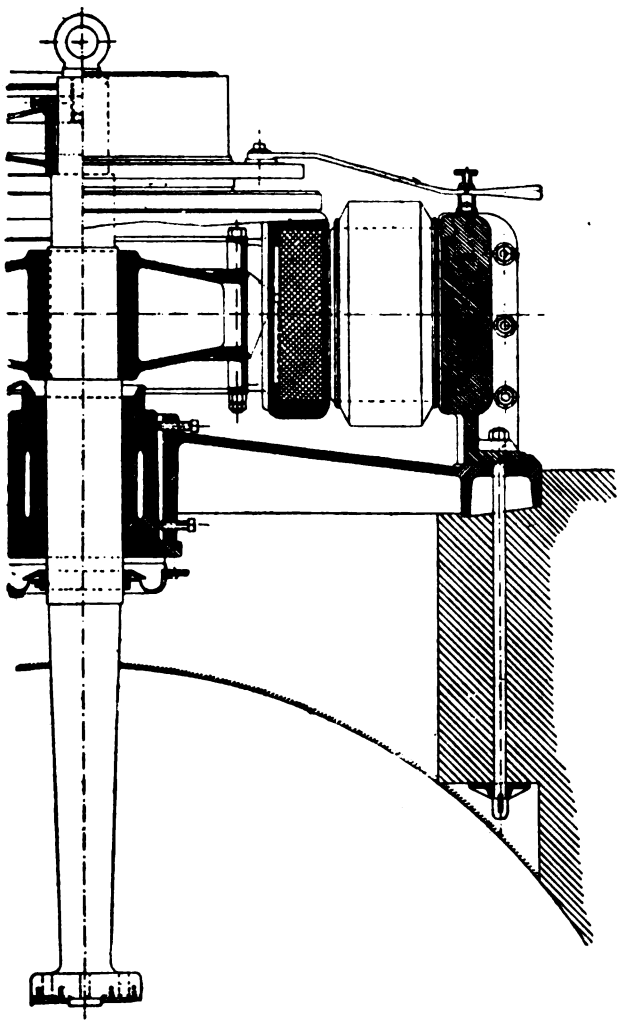
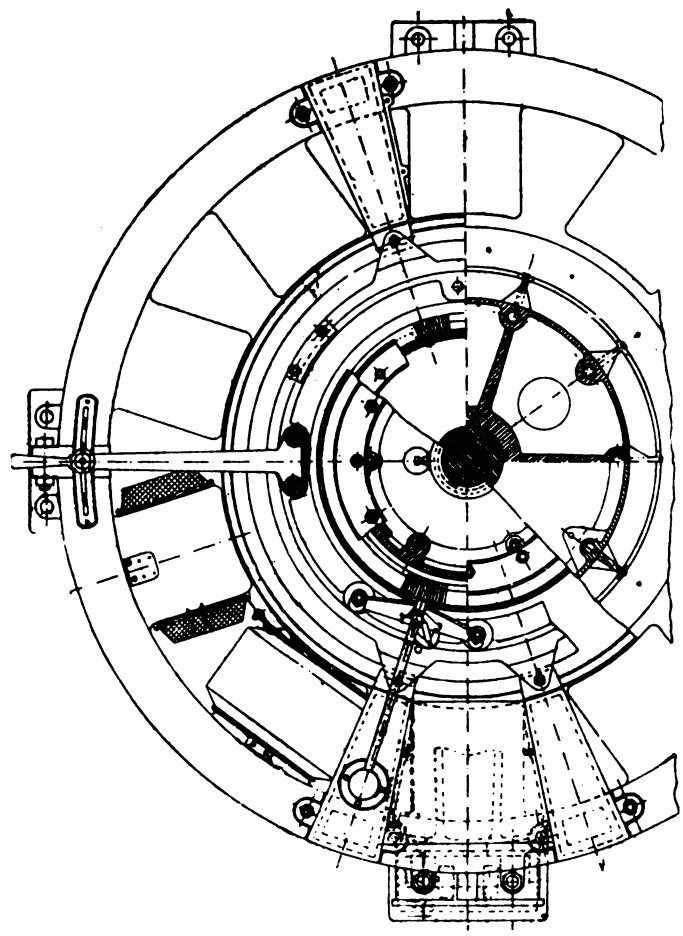
"PROF. FORBES ON HIS CRITICS."

SIR,—The letter from Prof. Forbes in your issue of the 29th ult. raises the important question, "Shall papers read before scientific societies be criticised or not?" Apparently Prof. Forbes's opinion is that only favourable criticism is permissible. He also objects to give any further information necessary for the intelligent discussion of his paper. Several speakers asked for such further information, and were duly rebuked. My own case was as follows: I found on investigation that Prof. Forbes's conduit was liable to two principal difficulties, either of which can be reduced at the expense of the other. The one is the danger of flashing across between the two conductors of the same circuit if placed on the same side of the conduit. The other is the effect of mutual induction between the two circuits if all the leads are carried on one side and all the return wires on the other side of the conduit. The mutual induction would, I found, prejudicially affect the working of the system. It was therefore necessary for me to ask Prof. Forbes which of these arrangements he had adopted, as the information was not given in the paper. He replied to my query, "I decline to answer that." I will leave your readers to decide whether this remark was justified.



Oerlikon Dynamo.—Sectional Elevation.



Oerlikon Dynamo.—Plan.

Turning to the vexed question of the general policy of the Niagara Construction Corporation, it would be to the point if Prof. Forbes would tell us a little more about the "disbursements of 90,000dol. for European professional advice." How much of this was paid to the members of the first commission held in Exhibition-road, whose report was not carried out, and how much to manufacturers? This commission consisted of many eminent men, who would require a large fee for their valuable assistance both by name and professionally. Any money paid them, although it may have been a large amount, on account of valuable information not used would not give much satisfaction to electrical firms who have spent some thousands of pounds (not dollars) in preparing schemes only good enough to be of general use to Prof. Forbes as adviser of the Cataract Construction Corporation. That he received such assistance from plans submitted is acknowledged by him in his paper, where he claims no great original work in the design of the machinery. In fact, it would be of great interest to know how many thousand dollars have been received by European manufacturers—not consulting engineers—for professional advice. Still, from what I remember, Mr. Ferranti in his condemnation of the policy of the company did not blame Prof. Forbes personally, and I consider that the personal element in the discussion was not introduced by the critics.

As regards the statement that Prof. Forbes's alternator is like a "Brown" machine, I would ask you to reproduce, if possible, the blocks given on pages 345 and 346 of Mr. Gisbert Kapp's book on "Dynamos, Alternators, and Transformers." I must confess that when I accidentally came across a "pull" from this block the other day I thought it was the Forbes machine. The electrical and magnetic parts are similar, but the mechanical details differ, as the armature of this dynamo revolves inside a fixed field. Electrically the difference is zero, but the balance in favour of the fixed field may explain Mr. C. E. L. Brown's condemnation of the Forbes design. The construction of the bearing inside the armature is the doubtful point, and the attendant who entered the space inside the armature (so much thought of by the designer) to attend to this bearing if heating, would take his life in his hands. The confined space with, say, melted white metal flying round, and 24 tons of iron travelling at 100 miles per hour all round you, would be a trifle too hot for a nervous man. The Brown machine was certainly a direct-current one, but the alteration necessary to evolve the two-phased windings is not a large matter.

I do not blame Prof. Forbes for using, as he must involuntarily do, the information obtained from the designs sent in and from the many works he visited when retained by the Niagara Construction Corporation; but we European engineers have a just right to grumble when this informa-

Digitized by Google

tion is placed at the disposal of an American firm who, we are given to understand, are afraid to work at more than 2,000 volts.

Also, was it good taste or professional etiquette to turn on Mr. W. M. Mordey as Prof. Forbes did in his reply, after having been allowed the privilege of experimenting on the Mordey alternator?—Yours, etc.,

R. W. WEEKES.

Westminster, January 3, 1894.

ELECTRIC TRACTION AND THE BOARD OF TRADE.

SIR,—Since the publication of the draft Board of Trade regulations for electric tramways, we have been expecting to find attention called in the Press to the serious bearing these regulations, if confirmed, will have on the infant industry of electric traction. But, much to our surprise, the matter seems to have escaped notice, and we, therefore, crave space for a few remarks on the subject.

In the first place, the regulations appear to us to be out of harmony with the report of the joint committee which considered the traction question last June, and which recommended that the Board of Trade should draw up rules calculated to give effect to the committee's views. The following extracts from the report clearly indicate the committee's intentions, the italics being ours: "The committee, having regard to the evidence before them, are of opinion that it is not, in the present state of electrical science, in the interest of the public to insist upon electrical tramways using an insulated return conductor, and that such insistance would retard the development of electric traction." "The undertakers shall take all reasonable and proper precautions in constructing and using their lines, circuits, and other works, so as not injuriously to interfere with the working of any wire, line, or apparatus . . . . provided always the undertakers shall be deemed to take all such reasonable and proper precautions as aforesaid, if and so long as they adopt and employ, at the option of the undertakers, either such insulated returns or such uninsulated metallic returns of low resistance, and such other means of preventing injurious interference with the electric wires, lines, and apparatus of other parties and the currents therein as the Board of Trade shall direct, and in giving such directions the Board *shall have regard to the expense involved, and to the effect thereof upon the commercial prospects of the undertaking.*" The Board of Trade are empowered by Section 3 of the report to make rules "for regulating the employment of insulated returns or of uninsulated metallic returns of low resistance, for preventing fusion or injurious electrolytic action on gas or water pipes, or other metallic pipes, structures, or substances, and for minimising *as far as is reasonably practicable*, injurious interference with the electric wires, lines, or apparatus of other parties, whether such lines do or do not use the earth as a return." In their third and fourth recommendations the committee express themselves altogether in favour of metallic circuits for telephones and railway block signals. Briefly, the committee considered that although every reasonable precaution was to be adopted in favour of earthed telephones and water-pipes, the existence of these things was not to stop nor even to hamper electric traction. The Board of Trade respond to this expressed intention by proposing their regulation No. 14: "In the disposition, connections, and working of feeders the company (undertakers) shall avoid injurious interferences with any existing wires." This was exactly the view of the National Telephone Company when they tried to stop the Leeds tramway. It was a view they could not persuade Mr. Justice Kekewich to adopt, it was a view they could not persuade the joint committee to adopt; and yet after everything that has passed, the Board of Trade calmly go back to it, and seek to make it law. There is no qualification such as the committee indicated to the proposed regulation, and its adoption will place electric traction in a worse position than ever. By regulation No. 15, "sparking at the rubbing and rolling contacts in any part" is absolutely forbidden. Is that "reasonably practicable"? We say that it is not. The indifference displayed by the electrical profession in the matter may be perhaps due to the knowledge that the Board of Trade intend to take the opinion of the Council of the Institution of Electrical Engineers on the regulations before issuing them; but a word of warning appears necessary on this point. The National Telephone Company are most influentially represented on the Council by gentlemen who are, or have been, their retained experts. No doubt it may be said that these gentlemen will not allow their conduct at the Council to be influenced by their retainers, but can they avoid insensible bias, and would it be just to their employers if they did? We would suggest that the only proper course is for the Council to exclude all such partisans, whether for or against traction or telephones, from their deliberations when the rules are under consideration. That the National Telephone Company are alive to the occasion would appear to stand confessed by the circular-letter issued from their offices on December 8 to their employés and others, suggesting that they should substitute on their ballot-papers the name of one of the company's officials for that of one of the Council's candidates, and also endeavour to influence their friends to do the same. The manœuvre did not succeed, but it is significant. It is also noteworthy that the list of Mr. Ansell's proposed representative council does not include any member for traction, whilst telegraphs and telephones are to be provided with three.—Yours, etc.,

Preston, Dec. 30, 1893. BENNETT AND DRUCE.

LIGHTING OF KINGSWOOD.—A CORRECTION.

SIR,—The directors of the Western Counties Electric Light and Power Syndicate, Limited, have had their attention called to the report contained in your issue of the 22nd ult., under the heading of "Kingswood," in which a statement occurs that at a meeting of the Local Board complaints were made as to the inferior lighting of the district, and that the answer was that the current was at fault.

I am instructed by my directors to write you at once, requesting you to be kind enough to insert a total denial of any statement as to the inferior quality of the lighting or the current being at fault. The fact is that the lighting at Kingswood will compare favourably with the electric lighting of any town in the kingdom. As a matter of fact, in some of the by-streets the lamps supplied are of only 25 c.p., that being the power required by the Kingswood Local Board, and contracted for by Messrs. Parfitt and Son, who have sold their patents and business to the syndicate. The Local Board were told at the time that lamps of only 25 c.p. would not be satisfactory; but the Local Board did not feel justified in paying for lamps giving greater light, and the contract was carried out by Messrs. Parfitt and Son in accordance with the terms required by the Local Board. There is no cause whatever for any complaint, and, indeed, the syndicate have supplied more light than that contracted for.

Some few months ago complaints were made by some of the residents that the lighting in these by-streets was not sufficient (as was anticipated would be the result by Mr. Parfitt when he warned the Local Board against having lamps of such small candle-power), and it was then arranged that the surveyor of the Local Board, with the engineer to the syndicate, should examine and test each lamp in the district. The result was that some of the lamps were found to give 31 c.p., and no lamp was found to give less than 28 c.p., so that it will be seen that in no case was there given less than 3 c.p. above that contracted for, and in many cases as much as 6 c.p. above.

My directors, therefore, consider that complaints are both unfair and improper, and I am sure you will concur with me, that inasmuch as you have unintentionally done an injustice to the syndicate by inserting the paragraph, you will at once remedy the injustice by inserting this contradiction.

I may add that in the main streets lamps of 120 c.p. are supplied, and the light is as brilliant and as good as can be found anywhere in England; indeed, the highest authority on electric lighting in the kingdom has reported in the most eulogistic terms both upon the system and the light.—Yours, etc., S. F. ANDREWS, Secretary.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XI. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

1893 PAST—1894 PRESENT.

"Hearty Good Wishes."

A review of the year naturally recalls the topics dealt with twelve months ago, to find many of them as prominent—some more so—at the present time as in last January. A constant stream of enquirers ask how best to prepare their sons for taking a good position in the electrical industry, and have to be answered in due course. We have thought it would be well if all employers of labour would print in large type, and keep conspicuously before all enquirers as to opportunities in the industry, a paragraph from one of Mark Twain's replies. We will parody the reply, in order to apply it to our particular needs, and would make it read thus:

"Electrical engineering, like all other professions and all other occupations, is cramped and hindered for want of men to do the work, not for want of work to do. When people tell you the reverse, they say what is not true. If you desire to test this, you only need hunt up a *first-class* designer, manager, foreman, or mechanic in any branch of the industry, and *try to hire him.* You will find he is already hired. He is sober, industrious, capable, and reliable, and is always in demand. He cannot get a day's holiday except by courtesy of his employer, or of his city, or as by law proclaimed. But if you need idlers, shirkers, half-instructed, unambitious, just-as-good-as-my-neighbour men, apply anywhere. There are millions of them to be had at the dropping of a handkerchief."

Is not this too true? Is there a master or a conscientious manager who is not driven almost crazy because of the lackadaisical attitude of the men he has to employ? Can he give general instructions as to the work to be done and leave his men in the sure and certain hope that the work will be well and correctly done? He can't. Half of the bad work of the present day is not because the masters and managers desire bad work, but because many of the men they employ have no spark of morality in their whole composition. One of the technical papers the other day reproduced a large number of mason's marks. These marks, if they indicate anything, indicate that the labourer took a pride in his work, and was proud to indicate to all and sundry the particular part of the building for which he would take credit. The majority of men engaged in the electrical industry would not care to specially indicate their work, and if they did indicate it, the work would not bear inspection nor win any credit. And this is towards the close of the nineteenth century—an age said to be civilised, when compulsory education holds sway, and trades unions govern the land. Well, there is plenty of work for first-class men, and for our part we would suggest that those who are satisfied to be as good as their neighbour ought to be urged to emigrate. Self-help is a lost cry nowadays, but it is useful in the long run; and though in one sense knowledge may not be power, it is a great factor in determining a man's position.

"Nil admirari, prope res est una,
Solaque, quæ possit facere et servare beatum."

Thus Horace says, and his words have been rendered:

Digitized by Google

"Not to admire, is of all means the best,
The only means, to make and keep us blest."

We certainly are amongst those who do not admire all the tactics of these days.

Mark Twain's term "first class" brings to our mind an important consideration referring to consulting engineers. We fear some municipalities are providing a rod for their own backs, and are certainly employing consulting engineers that can by no stretch of the imagination be termed first class. It has long been a question for us whether a deliberate libel would not be the best way to deliver the profession from quacks—but why should we pluck the chestnuts from the fire when professional men remain silent themselves? Central stations exist which are known to be wrongly designed, which will surely lead to municipal troubles, which indicate most clearly incapacity to understand the requirements of the position and place, while it is impossible to say the apparatus used is not good. We think we could show in more than one case that each average horse-power year must earn from £50 to £250 net profit in the year to obtain satisfactory pecuniary results. Is this possible with electric light or power work? Mr. Crompton might tell us what a horse-power year ought to bring, not only from estimate, but from experience, for probably his records at Kensington are as extensive, detailed, and complete as any that exist. If with a given initial outlay a sufficiency of power is not provided—that is, earning capacity is unprovided—how can a station pay? And this provision is one of design, and has nothing to do with the excellence of the apparatus provided. In other words, a station may be equipped with the best of everything, and yet unable to pay its way. The one great fault is the weakness of the consultant, who on purpose to obtain work plays to the gallery, instead of designing for futurity. The saving of an initial expenditure of five thousand pounds means probably an altogether unnecessary expenditure of twenty thousand within five or six years. Thus the consultant who advises properly is unemployed because a brother professional troubles nothing for the future and plays all his cards for the immediate present. The latter takes as his motto another of Horace's sayings—*vide* Epistle to Mæcenas—wherein he is advised thus:

"My friend, get money; get a large estate
By honest means; but get, at any rate."

Speaking of central stations, we would remind our readers that probably more money is spent upon wiring and fittings than upon apparatus in the station and the mains. The manufacture of meters has attained very large proportions; but these are generally hired, and their purchase forms part of the outlay of the supply concern. The wiring and fittings, however, are very often the work of outsiders, and upon this work the success or failure of the central station too often depends. It is all very well to argue that current will not be laid on till the inspector from the central station is satisfied with the work. The inspector is but mortal, and cannot do impossibilities. Things made to sell generally look all right, and things made to pass an examination very often pass, and afterwards develop faults which are directly due to bad workmanship or materials. That both are common no one denies. Two anecdotes may be told to confirm this. Not long since a responsible manager said of a firm that was cutting a dash and doing a large amount of wiring: "That firm's work is known to be anything but good; yet there it is, and it is passed." Again, a firm trying to make a reputation for good work, being asked to purchase certain materials from a nicely got-up price-list, said, "No, these materials are by no known maker; and we refuse to purchase unless we know the makers and that they are of good repute." The central station has enough cares of its own without suffering for the sins of other people; yet any failure is laid at its door, and in many instances householders delay putting in the light because a friend or neighbour records a variety of failures. The most perfectly designed and equipped central station cannot guard against these evils. In connection with central-station design we are becoming daily more convinced that insufficient attention has been given to storage. This may seem a wild statement; but we will take the doubter to more than one station where facts would, we think, prove too strong for any abstract theory as to what ought to be, but is not.

Mr. G. Offor points out on another page that the idea of certainty in electric light matters is not yet impressed upon men's minds. Indeed, the general opinion is to the contrary, that it is uncertain, and a whole cartload of facts and statistics will not mend matters. Give a lie a start of twenty-four hours and you will never overtake it, so that, in like manner, if we give as a fact one lamp being out for five minutes, the history of that lamp will swell into all the lights of the house, street, or town out for an hour. No doubt our contemporaries, like ourselves, are inundated with trivial complaints, in which molehills are made to appear as mountains, and which after being sifted are found wanting and go unrecorded, except when the rumour gets into the hands of the gas journalist. Every effort should, then, be made to have wiring, fittings, distribution, and central-station apparatus as perfect as possible. It is not enough to trust that things will continue all right because they went all right yesterday. Supervision should be untiring, keen, and exhaustive. Even then the design of many stations leaves out storage, and is content with a reserve of apparatus. Is it not a fact that initial simplicity has very much to say for the booming of high-pressure systems? Are we sure, and do facts and figures carry conviction, that transforming up and transforming down losses here and losses there means economy? Shall we come to the time when a reserve of apparatus, rather than a reserve of storage, will not bring—

"Weeping, weeping, late and early;
Walking up and pacing down,"

and a mourning deep as can be in business matters? The engineers in charge of central stations and the managers of supply companies, if they were to tell the truth, would, without exception, say, "Give us at any rate some storage." Reserve machinery means time lost to get into action. Storage means a turn of a switch and time to bring other reserves

Digitized by Google

into play. But, of course, there is always the question of initial cost, as well as simplicity, and hitherto the advocates of high pressure have obtained favourable consideration.

Another question of the first importance has been touched on by Mr. Mordey in a letter to us. Every word of his statement seems to us important. It is as follows: "It appears to me that the electrical engineering business is changing rather in the distribution of work, than in any other way—large contracts for all sorts of plant going to the large manufacturing concerns, and small separate installations, wiring work and special applications to the smaller concerns and to those who specialise. I think there is, perhaps, a growing inclination to adopt the plant and practice of the larger concerns throughout for entire jobs, rather than dividing such jobs up amongst a number of firms. This is as it should be, as it places the bulk of the responsibility on one instead of on a number, and prevents waste of money and time caused by a number of contractors having to work together on one job."

The question of design again comes in, and if the consultant specifies certain boilers—*e.g.*, because they have been made fashionable by adoption in certain quarters—without knowing much about boilers himself, he is likely to err. We have long insisted that the throwing together an installation is a mistake. Every part should be designed in connection with every other part, and when so done the result is more likely to be satisfactory than when engines, boilers, dynamos, etc., are selected either because of cheapness or of fashion. The concentration of responsibility is much to be desired. An example of the value of this is seen in the success of the Liverpool Overhead Railway, where the company is so satisfied with the work of the contractors that it has taken over responsibility before the time originally specified for doing so.

Our desultory remarks must, however, come to an end. We had intended to say something about ourselves, but that subject, though it may be interesting to individuals, is of no special interest to the general reader. We are told that we have been tolerably good in the past, and if we promise to behave better in the future—what more can be expected? As usual, we have collected a number of reports from a variety of companies and firms connected with the industry, which follow hereafter:

J. E. H. Andrew and Co. state that during the year they have supplied engines for about 25 private installations, a total of 300 effective horse-power, which would be equal to 3,000 16-c.p. lamps. Among other places, they have supplied two engines, 57 effective horse-power, Paragon Music Hall, London; one engine, 35½ effective horse-power, Bow Theatre, London; two engines, 22 effective horse-power, Arcadia, Devonport, Plymouth; one engine, 20 effective horse-power, Lads' Club, Denton; one engine, 20 effective horse-power, Hengler's Circus, Dublin—or a total of 154 effective horse-power, say 1,500 16-c.p. lamps. In addition to this they have done a considerable amount of exhibition lighting at various times of the year with engines from 2 to 55 effective horse-power—for example, 55 effective horse-power for driving direct arc lighting at the last Brewers' Exhibition, Stanley Show, and the Fat Cattle Show at the Agricultural Hall. They have a considerable number of engines on order at the present time, and are hopeful as to the prospects of the coming year, and with special reference to gas-engines for electric lighting they consider the use of them is decidedly on the increase, and during the next year a very extended use will be made of the gas-engine for central-station work. They have a special tandem-cylinder engine now manufacturing, which they contend is well adapted for driving dynamos for direct lighting, and anticipate a large share of the orders for central-station work with this improved type of gas-motor.

R. Aylmer reports that though this is the first year of introducing the new Leclanché-Barbier batteries, they have met with great success, and are being largely used by many of the railway, telegraph, telephone, cable, and other companies, scientific institutions, Indian and colonial governments, and electrical engineers, as well as by a considerable number of private firms.

Browett, Lindley, and Co.—During the past year this firm have had their full share of work, and amongst other contracts which they have executed may be mentioned all the steam-engines for driving the electric light station at Derby, to the order of Messrs. Siemens Bros. and Co., Limited, London; two high-speed horizontal engines for Coventry electric trams (overhead wire system), to the order of the Electric and General Contract Corporation, Limited, Westminster; two engines for the City of London electric light station, coupled direct to the General Electric Company's dynamos, and built to the order of the Laing, Wharton, and Down Construction Syndicate, Limited, Westminster; three engines for driving the electric light installation at the palace of his Majesty the Shah of Persia. Besides the above they have during the past year supplied many electric light engines to the order of their agents in Spain, Italy, Russia, and Austria, as well as a large number to the leading electrical firms for shiplighting and land installations. In addition to the above electric light work, the company have had a good supply of orders for horizontal and other types of engines for general commercial purposes, including a pair of vertical single-acting engines of 350 h.p. for direct coupling to a colliery ventilating-fan. The prospects for the coming year are extremely satisfactory, the company having in hand a large number of orders for the trade and private customers, including the engines for the Mullingar Lunatic Asylum (Ireland), engines for the Lancashire and Yorkshire Railway Company for shiplighting (third order), and about 40 other engines for shiplighting plants, etc. In central-station work they will also be very busy, having in hand the first of three 250-h.p. vertical compound engines, for the extension of the Derby town lighting, to the order of Messrs. Siemens Bros. and Co., Limited, of London; the whole of the steam-engines and condensing plant and accessories for Ealing central electric light station, to the order of Messrs. Latimer Clark, Muirhead, and Co., Limited, Westminster; the whole of the engines and condensing plant for the Chiswick central electric light station, to the order of Messrs. Bourne and Grant, London; the whole of the horizontal engines, etc., included in Contract 3 for the Corporation of Salford electric light station; the whole of the engines for Southport Corporation electric light station. It is only some two years since the company removed their business from Salford to their far more extensive

Digitized by Google

works at Patricroft, which are already taxed to their utmost capacity, and further extensions are already in contemplation.

BUMSTED AND CHANDLER.—This firm have during the past year supplied their well-known electric light engines, forced-draught fans, and ventilating-fans to a large number of steamships and steam-yachts, among which we may mention the Belgian Government mail steamers "Marie Henriette" and "Leopold II."; the London and North-Western Railway Company's steamer "Eleanor"; the Glasgow and South-Western Railway Company's steamers "Minerva" and "Glen Rosa"; the County Down Railway Company's steamer "Sleeve Douard"; the Thames, Woolwich, and Clacton Steamboat Company's steamer "London Belle"; Sir John Burns's Royal Mail steamer "Hound"; ss. "Tamboff" belonging to the Russian Volunteer Fleet; Messrs. W. Cory and Sons' steam-pontoon "Atlas No. 2"; the Bergen Steamship Company's steamer "Capella"; Baron Arthur de Rothschild's steam-yacht "Aries"; Mr. G. W. Fowler's steam-yacht "Puritan"; the White Star Company's ss. "Gothic"; the Lancashire and Yorkshire Railway Company's twin-screw steamer "Duke of York"; the Samuel Petroleum Syndicate bulk-oil steamers "Bullmouth," "Clam," "Elan," "Volute," "Trocas," and "Spondilus"; Messrs. M. Langland and Sons' steamer "Princess Beatrice"; the Portuguese Navigation Company's ss. "Zaire"; Messrs. J. and H. Harrison's ss. "Barrister"; the Chesapeake and Ohio Railway Company's ss. "Acanthus"; Mr. James Gordon Bennett's steam-yacht "Namouna"; and a mail steamer belonging to the Turkish Government. Electric light engines have also been supplied for a large number of land installations, among which we may mention the Woolwich electric light station, the London and North-Western Railway Company's rail mills at Crewe and at their pier at Holyhead Harbour, the North Stafford Railway Company's station at Stoke-on-Trent and their hotel at the same town, and Birch Hall, the seat of Mr. Buxton.

CLARKE, CHAPMAN, AND CO.—This firm has done a considerable amount of work during the year, principally in connection with the lighting of ships. The following is a brief summary: The s.s. "Baker Standard" has been installed with 80 16-c.p. and four miners' hand lamps; the "Mackay Bennett" has been fitted with a search-light projector complete; the "Trocas" has been fitted with a direct-coupled plant giving 1,800 watts, with 77 16-c.p. lamps, and a complete Suez Canal plant; the "Clam" has been also fitted with a direct-coupled plant of 70 16-c.p. lamps and two 200-c.p. lamps, and a complete Suez Canal plant; the "Spondilus" has been supplied with the necessary plant—viz., 60 16-c.p. and two 200-c.p. lamps, and a Suez Canal plant; the "James Brand" has been fitted with 84 16-c.p. lamps, and the necessary dynamos; the "Midnight Sun" was fitted with 350 16-c.p. lamps; the "Lucigen" with 88 16-c.p. lamps; the "Ronold" with 204 25-c.p. lamps, and an 18-unit direct-coupled plant; the "Mexican Prince," with 88 16-c.p. and four 32-c.p. lamps with a direct-coupled plant, and four miners' hand lamps; the "Italian Prince" with 58 16-c.p. lamps and combined plant; the cruiser "Yoshino" was wired for 420 16-c.p. lamps; the "Appomattox" was supplied with combined plant, 116 16-c.p. lamps and 20 32-c.p. lamps; the "Pfalz" with plant and 280 25-c.p. lamps; the "Austrian Prince" with a combined plant of 95 16-c.p. lamps; the "Chickahoming" with a combined plant of 126 16-c.p. lamps; the "Perthshire" with plant and 112 16-c.p. lamps; the "Georgian Prince" with plant and 95 16-c.p. lamps; the "Algoma" with plant; the "Seamew" with plant; the "Trinidad" with combined plant capable of lighting 258 16-c.p. lamps; the "Duffield" with plant and 114 16-c.p. lamps; "No. 221" ship with a plant and 140 16-c.p. lamps; the "Pembrokeshire" with plant and 77 16-c.p. lamps. Besides these, the joiners' shop belonging to Mr. James Laing has been wired and fitted complete with arc lamps; also the Holm Head Dyeworks, belonging to Messrs. Ferguson Bros., were fitted with a belt-driven dynamo, giving 10,500 watts, driven by a vertical engine, lighting 142 incandescent lamps and several arc lamps. Complete Suez Canal plants have been supplied to Messrs. Martin and Co.; a five-unit dynamo with engine has been supplied to the Seamless Steel Boat Company; F. Darling, Esq., of the Eldon Colliery, has been supplied with a pumping plant, which has a special motor pumping 150 gallons per minute; Messrs. Charleton and Co. have been supplied with a belt-driven dynamo for an installation for Mr. Woods, of South Shields, and also with a dynamo for J. Straker, Esq.; while the Wallsend Shipping and Engineering Company have been supplied with dynamos to give 24,000 watts and arc and incandescent lamps, and a somewhat similar plant has been supplied to the Mercantile Dry Dock Company, the dynamo giving 16,000 watts in this case; while to the order of Messrs. Poole and White a dynamo has been supplied to Baron de Rothschild giving 160 amperes at 140 volts pressure.

CROMPTON AND CO. supply us with the following short *résumé* of work carried out during 1893. The work is classified into headings, commencing with what we should call public works for either large corporations or municipal authorities. Prominent among these are the following contracts: Lighting of the Southampton Docks, for the London and South-Western Railway: This work has been carried out on the "low-pressure direct-current system," so as to facilitate the future use of motors, and the lighting at present consists of 60 arc lamps outside, and 1,000 incandescent lamps in the sheds. Lighting of the Great Eastern Railway Company's terminus at Liverpool-street and adjoining premises: The company is now carrying out important extensions in connection with the recent contract, which will increase the number of arc lamps to 200, and the number of incandescents to about 7,000. The work is carried out on the low-pressure direct-current system, the mains consisting in great part of bare copper strip carried on insulators. Bradford Joint-Stock Bank: This consists of 20 warehouse elevators each driven by a separate motor, the supply being off the Bradford mains, each elevator capable of lifting 11cwt. at a speed of 120ft. per minute. Southend Corporation: This is an extension of the former plant, and consists of a second Paxman engine and boiler, additional dynamos, and three additional cars. Crystal Palace: Complete lighting of the main nave, courts, etc., of the Crystal Palace with 90 arc lamps supplied with current from three Crompton dynamos, 500 volts, 30 amperes each, the lamps being 10 in series and three parallel. It is believed that this is the first time that such an arrangement has been carried out, at any rate on such an extended scale. Brighton Corporation: This consists in a set of 45 15-ampere lamps arranged to be supplied off the Corporation's mains, five in series and 230 volts—*i.e.*, 46 volts per arc lamp. Hove Electric Lighting Company,

Digitized by Google

Limited: Large extension orders of this company have been carried out both with the bare system of mains and for the permanent plant and buildings now rapidly approaching completion. Dewsbury Corporation: Central-station contract in accordance with the terms recently published, on the direct-current low-pressure system. Compagnie Hydro-Electrique, Antwerp: This is a contract for mains only on bare copper underground system. The present extent of this order is about 13 miles of streets. London and India Joint Dock Company: Thirty-two arc lamps for their new arrangements of lighting at Albert Docks. Southampton Electric Lighting Company: Considerable orders for extension of plant owing to the rapid increase in the output of this company. Hove Commissioners: Complete wiring and fittings for the new Town Hall. In addition to the places included in above list, Messrs. Crompton supplied their new and improved type of arc lamp to the following places: Hull Corporation, for the Market-place (20 lamps); Charing Cross Station (28 lamps); London and North-Western Railway (20 lamps); Glasgow Corporation (80 lamps); Lancaster Corporation: Oxford Electric Lighting Company; Richmond Corporation, through Messrs. Latimer Clark, Muirhead, and Co., Limited; also 30 arc lamps and electrical portion of installation, both for the arc and incandescent lighting of the Batavia Exhibition in Java, through Messrs. J. Birch and Co. Among a large number, the following house installations are the more prominent ones: S. S. Berger, Esq., Knebworth, complete installation of 72 lights, with oil-engine and Crompton-Howell battery; G. Buxton, Esq., Theydon Bois, complete installation of 110 volts, with steam plant and battery; J. H. Tritton, Esq., Lyons Hall, complete installation of 70 lights, with oil-engine and Crompton-Howell battery; Rev. W. A. Duckworth, Frome, 90 additional lights fixed, also generating plant and battery; J. Corbett, Esq., Droitwich, installation of 57 27-plate Crompton-Howell cells, also the lighting of the estate offices. Amongst sundry work not included in the above, the firm have supplied, or have in hand, plants for the complete lighting of steamships for the Société Anonyme John Cockerill; to the Great Eastern Railway; the complete electric lighting of her Majesty's training ship "Worcester"; the Stanton Ironworks Company, for the extension of their new haulage plant; Messrs. Simpson and Co., four sets of plant for lighting pumping stations; the Free Trade Wharf Company; Messrs. Barclay and Fry; Messrs. John Mowlem and Co.; also laboratory installation, consisting of dynamo, battery, etc., to the University College, London. Also they have supplied through their agents, Messrs. J. C. Howell, Limited, of London and Llanelly. and Messrs. Corlett Electrical Engineering Company, of Wigan, a large number of motors for a variety of purposes, but more especially for use in collieries and mines for underground electrical haulage, pumping, ventilating, etc. Also, through their agents (the Crompton Electric Supply Company of Australia), among other plants, the following: Complete installation plant for large business premises in Sydney, consisting of three Davey-Paxman vertical compound "Windsor" engines, coupled direct on the same bed-plate to three dynamos, each having a capacity of 30,000 watts. Complete plant for the lighting of large meat stores at Sydney; pumping plant for a large colliery in Newcastle, the first electrical pumping plant ever installed in the colony; complete central-station plant for the Perth (Western Australia) Gas Company, for the supply of private lighting, together with a complete system of distributing mains through a large portion of the city; additional plant for the *Daily Telegraph* office, Sydney; complete lighting plant for mines, and a large number of other installations.

Doulton and Co., London, have been busy throughout the past year at their well-known Lambeth potteries, and also at their several works in Staffordshire, in the production of pottery for electrical purposes. The high quality of their manufactures has been recognised at the Chicago Exhibition by seven highest awards. This is the largest number granted to any firm of potters in the world, and it is gratifying to know that the honour was secured by a British exhibitor. An important branch of the works at Lambeth is devoted to the manufacture of telegraph and telephone insulators and pottery parts for electrical apparatus in strong vitrified stoneware, and the same articles are produced in porcelain at their Burslem works. During the past few years a new impulse has been given to the manufacture of vitrified stoneware for insulating purposes owing to the adoption of this material as the most suitable, because of its strength and durability, for bare copper electric light mains. Messrs. Doulton have laid themselves out for the supply of such insulators in large quantities, and have designed plant for the manufacture by an improved method which ensures cheapness combined with great strength and high and permanent insulation. During the past year these insulators have been supplied to the Corporations of Oldham, Aberdeen, etc. At the beginning of the year Messrs. Doulton introduced their stoneware underground conduit for insulated electric mains. The conduit is the cheapest system which provides a separate duct for each cable, and it is easily laid, strong, and imperishable. Judging by the way it is being adopted both by London and provincial supply companies, it evidently meets a want and merits the attention of engineers and contractors. Messrs. Doulton are now also offering a stoneware culvert to be used in place of concrete culverts constructed *in situ*. The stoneware culvert is supplied in short lengths, which can be rapidly laid and jointed. We can only give a passing reference to this firm's other productions, such as plumbago crucibles, stoneware apparatus for chemical manufactures, water-filters, etc., which are largely made.

Drake and Gorham.—This firm have had a very rapid increase of work during the past year, for the number of installations carried out reached a total of no less than 150. The installation at Chatsworth for the Duke of Devonshire, carried out by Mr. Drake, the senior partner, of over 850 lights, is, of course, the most important, and in our last issue will be found full particulars, with illustrations of the arrangement of the plant. A few of the other installations are the following: Old Warden, for Major Shuttleworth, steam plant, over 400 lights; Galtee Castle, Abel Buckley, Esq., 150 lights; Hindhead, Miss James, petroleum plant, 80 lights; Brockhampton Court, for Mr. Foster, 130 lights; Major Browne, Callaly Castle, steam plant, 600 lights; Lieutenant Walker Munro, Rhinefield, steam plant, 550 lights; H. O. D. Davidson, Esq., Elmfield, gas-engine, 180 lights; H. F. Tiarks, Esq., Foxbury, gas-engine, 180 lights; A. M. Hallet, Esq., Goddington Hall, petroleum, 150 lights; Lord Cantelupe, Bexhill, gas-engine, 200 lights; Manchester, Liverpool, and District Bank, head office, new plant rearrangement and extensions; Manchester, Liverpool, and District Bank-chambers, adjoining, 120 lights; Richmond sewerage works,

Digitized by Google

steam-engine, number of lights equivalent to 105 16-c.p. lights; Reiss Bros., Manchester gas-engine, 200 lights; E. Brook, Esq., Hoddom Castle, gas-engine, 150 lights; Gustav Behrens, Holly Royd, gas-engine, 120 lights. They have arranged for a turbine plant for A. M. Ogston, Esq., Ardoe, the petroleum-engine previously installed by them being used as a stand-by when the water falls short. Among the more important of the wiring are the following: The Great Northern Railway Offices, 650 lights; the Bank of England Head Office, 550 extra lights; the Bank of England, Leeds, 250 lights; the Bank of England, Bristol; the Bank of England, Hull; the Right Hon. Baron H. de Worms, Grosvenor-street, 180 lights; Nicholas Wood, Esq., Lowndes-square, 150 lights; Sir E. H. Carbutt, Hyde Park-gardens, 100 lights; G. Cawston, Esq., Upper Brook-street, 150 lights; A. Spicer, Esq., Lancaster-gate, 130 lights; Union Bank of London, Chancery-lane; Union Bank of London, Holborn-circus; Union Bank of London, Regent-street; they have also remodelled Mr. Rabbits's installation at West Hill, where there are now over 200 lights; the London Brazilian Bank, London; A. G. Sandeman, Esq., Grosvenor-street; Alliance Assurance Office, St. James-street branch, 100 lights; W. H. Spottiswoode, Esq., Sloane-street; Brighton Tennis Court, 100 lights; Manchester and Salford Savings Bank, 150 lights; G. L. Beeforth, Esq., 150 lights; Balliol College, 100 lights; Rock Life Assurance Office, 150 lights; Balliol House, for A. L. Smith, Esq., 50 lights; Westminster School of Medicine; Huth and Co., Tokenhouse-yard, 300 lights; Agnew and Sons, Picture Gallery, 150 lights; W. Boyes, Esq., Scarborough; Sir Guy Campbell, Palace-gate; A. F. Wallace, Esq., Hyde Park; Manchester, Liverpool, and District Bank, King-street, 100 lights; London and River Plate Bank, new premises, Princes-street; Messrs. S. Behrens and Co., Manchester; the Club, Scarborough. During the year they have been compelled to open a permanent branch in Manchester, owing to the amount of work which they had continually in hand in the district. In Scarborough they have also opened a branch, as it was found absolutely necessary to cope with the large number of installations in progress. In fact, the extra work all round has necessitated their adding several offices to their already commodious premises in Victoria-street. The sale of the Cardew earthing device and Cardew voltmeter continues to keep up well, and there is a continual demand for the ring and spring contact switches made under their patents. The sale of the D. P. batteries has more than doubled during the year, and contractors have begun to appreciate the advantages they possess of high rates of discharge combined with great capacity. They have also been entrusted with the rearrangement and reconstruction of the electrical apparatus in the launch "Florentia," the ordinary running speed of which is now 6½ miles an hour, and at recent trials a maximum of nine miles an hour was obtained. They have also fitted up the electric launch "White Wings" for Messrs. Salter Bros., of Oxford, the normal speed of which is 6½ miles an hour.

Ernest Scott and Mountain have during the past year, and particularly the latter end of the year, been extremely busy in their electrical department. During the year they have installed a total of 69 installations in various parts of the country, the total number of incandescent lamps installed in connection with these installations being 13,000. In addition to this they have installed 153 arc lamps of their own manufacture. The total number of dynamos supplied, and not taking into account a large number of orders in hand at the present time, is 137, their average capacity exceeding 200 lights each. They have also been extremely busy in electric transmission of power machinery, and have supplied, and have on order, six large sets of plant. Amongst the most important electric light installations may be mentioned the following: Combined engines and dynamos for the Japanese cruiser "Yoshino," and the Chilian cruiser "Blanco Excalada"; combined engine and dynamo and complete installation for Heckmondwike boot and shoe factory, the installation consisting of 700 incandescent lamps; complete installation for the Gateshead Co-operative Society, consisting of two gas-engines, two dynamos, and about 400 incandescent lamps; complete installation for Seaham Harbour Co-operative Society, with gas-engine and dynamo, and about 200 incandescent lamps; complete installation for Messrs. Chadwick Bros. for lighting of new spinning mill, the plant consisting of three 400-light dynamos, and about 800 incandescent lamps, also complete lighting of new offices, with dynamo, engine, and 200 incandescent lamps; complete electric light installation for Messrs. Jonas Brook and Bros., Huddersfield, plant consisting of two 800-light dynamos and 1,400 incandescent lamps; complete lighting installation for the Leicester Co-operative Society, consisting of gas-engine, dynamo, and 400 lamps; installation for Crossfield, Barrow, and Co., sugar refiners, Liverpool, consisting of two vertical steam-engines, 400-light dynamo and 150-light dynamo, and about 400 lamps; installation for New Craig House Asylum, Edinburgh, consisting of four compound engines of 60 h.p. each, four 400-light dynamos, and about 1,400 incandescent lamps. In addition to the above lighting contracts the firm have in hand the following pumping plants: Complete electric pumping plant for Lothian Coal Company, consisting of three engines of 120 h.p. each, two 60-unit dynamos as generators, two 60-h.p. electric motors, and two sets of pumps, each to deliver 200 gallons of water per minute against a head of 650ft.; electric lighting and pumping plant for the Coltness Iron Company, consisting of three dynamos, electric pumping plant to deliver 100 gallons of water against a head of 150ft. for supplying the colliery and houses with water, complete lighting plant for the colliery, and lighting plant for 34 workmen's cottages; installation for the Edinburgh roperies, consisting of horizontal engine of 80 h.p., dynamo to run 600 lamps, and complete lighting of roperies. During the year the firm have shipped a considerable number of lighting plants, including the plant for the lighting of the Imperial Paper Mills, Calcutta, and a large cotton mill in Calcutta. They have also in hand a contract for two complete sets of train-lighting plant for India. They have also supplied to South Africa a number of dynamos, and have in hand a large electric pumping plant for Johannesburg, and electric lighting plant for a rice factory in China. Amongst important dynamo orders in hand at the moment may be mentioned an order for seven large dynamos for the English War Office, and also orders for dynamos for India.

Electrical Company.—This company, as in former years, have continued their policy in 1893 of not entering into competition with their customers, who are largely composed of installing firms. In the past year they have had the satisfaction of bringing to the front some approved electrical constructions which have met with universal approval,

Digitized by Google

among which may be mentioned their Dolivo measuring instruments—viz., ammeters and voltmeters; likewise the handy testing sets for measuring insulation resistance. The new insulating material, "Stabilit," is rapidly being recognised. There is at present in general but a limited demand for electromotors, which must be considered a great pity, as the more frequent adoption of these motors would tend to increase the day load of the central stations, a circumstance eagerly desired by all central-station engineers, as it would not only be a source of great saving to them, but equally so to the users of power. So far, great success has been met with in direct-current motors, both for ventilating and refrigerating purposes. The multiphase motors, which have neither brushes nor commutators, will be put on the market in 1894, and their great advantages for mining and navigation purposes, where sparking is most undesirable, are evident. The competition for lampholders is, of course, very keen, but the company state that they have succeeded in putting on the market a type of holder which has not been found fault with by the keenest of buyers. They have every reason to be proud of the success of the "Luna" arc lamps. Two of the most successful installations of these lamps were carried out by Messrs. Vaughan and Brown at "Old Paris" and at the Agricultural Hall. The former was an installation of 11 of the "Lunas," which behaved splendidly throughout the whole run. The latter was an installation of 42 in series, running off a gas-engine, and the fact that the lamps burned without a single hitch during the Brewers' Exhibition, the Cattle Show, and Stanley Show, speaks for their steadiness and accuracy of construction. A firm going in largely for arc lamps is, of course, bound to meet with much disappointment before central-station engineers consent to adopt any special type. These lamps, it is said, have earned for themselves the most flattering opinions of experts. The fittings department is doing an increasing business, the electroliers, as well as a new series of cheap plain fittings, and likewise the cigar-lighters, having commanded a large sale. With regard to incandescent lamps, the business done in this line has been most satisfactory, and if orders continue as they come in at present, then accordingly it is estimated that the sale per annum will amount to about half a million lamps.

EDMUNDSONS, LIMITED.—Messrs. Edmundsons have during the past year fitted up private installations for at least a dozen large country mansions. In London also they have been busy, and among the many works carried out the most important have been the fitting up the Junior Constitutional Club and the London School Board Offices, over 1,000 lights having been fitted in each of these buildings.

J. K. FAHIE AND SON.—This Dublin firm have been fairly busy during the year in the electrical way, especially in connection with consultation work. Several important installations in various parts of Ireland have been laid down to their specification and under their immediate superintendence, and a number of old installations have either been remodelled or enlarged. A popular addition to electrical literature, in the shape of a handy little book, entitled "House-Lighting by Electricity," by Mr. Angelo Fahie, M.I.E.E. (the junior member of the firm), brought out last winter, has, we understand, just exhausted its first edition.

E. GREEN AND SON state that during the past year the following electric light installations have been supplied with their fuel economisers for heating the feed-water to steam-boilers, and for which they have just been awarded the highest honours at the World's Fair, Chicago: Manchester, Nottingham, Lancaster, Burnley, Kingston-on-Thames, City-road Station (London), Dewsbury, Hampstead, Oldham, Londonderry, Sheffield, Brussels, Portsmouth, and Leeds. This list is sufficient to show the value of the apparatus as a coal saver wherever steam power is used. Numerous contracts are on hand for the coming year at nearly all the stations where the electric light is being introduced.

J. H. HOLMES AND CO.—During the year 1893, Messrs. J. H. Holmes and Co., of Newcastle-upon-Tyne, have built 173 dynamos for various purposes—*e.g.*, the lighting of mills, factories, shops, houses, and ships, power transmission, and electro-deposition of metals. These dynamos vary in size from ½ e.h.p. to upwards of 200 e.h.p., their total combined output being 2,342,335 watts, or expressed in electrical horse-power, 3,141—that is, equivalent to the power required to supply 41,844 lamps of 16 c.p., each taking 56 watts, as against 30,000 last year, or a total of 669,504 c.p., reckoning the same number of watts per candle. Amongst the principal ship installations, of which the total is 50, may be noted those of the "Rappkahannock," 132 lights, the "Shenandoah," 132 lights, and the "Kanawha," 132 lights, all built for the American cattle trade by Messrs. Alex. Stephens and Sons, of Glasgow; the "Hildebrand," 140 lights, built by Messrs. Hall, Russell, and Co., of Aberdeen, for the Booth Steam Shipping Company; the "Namouna," steam-yacht owned by Gordon Bennett, Esq., 112 lights, worked from accumulators. On this yacht there are also electric fans, electric piano, search-light, and small steam-launch plant, including small search-light. It must be remembered that there has been a general depression throughout the ship-building trade all the year, many of the smaller yards having been closed on this account. Last year this firm installed the electric light in 50 steamers—the same number as the present year. The land installations number 95. Among the larger mills were the Rock Cotton Spinning Mill, Ashton-under-Lyne, 560 lights; the Burns Ring Cotton Spinning Mill, Heywood, near Manchester, 600 16-c.p. lamps; the Stockport Ring Cotton Spinning Mill, 790 lights; the Yew Cotton Spinning Mill, Heywood, 898 lights. In each of these mills there are two dynamos, one capable of running all the lights, worked from countershaft off the main mill engines, the other running the pilot lights, and driven by a special engine. This latter is for use when the main engine is stopped, and when a general light is wanted to enable the workpeople to get about the mill in safety. The installation at Messrs. Walker, Reid, and Co.'s works, Dunfermline, consisting of 1,500 lights, supplied by two large dynamos, may also be mentioned. In this mill the lights are arranged in several circuits, entirely separate from one another, so that an accident to one circuit of the installation in no way affects any of the others. The principal development in the productions of this firm during the present year is the new drum-bar armature dynamo. In this machine the armature is, as the name implies, of the drum type. The armature conductors having to take heavy currents are made in the form of laminated copper bars, connected across the ends by means of spiral end connections. The armature cores are built up of thin discs of the best Swedish charcoal iron, insulated from each other with paper; to prevent undue heating, a fan is mounted on the shaft, which forces a current of air through the core. To obtain positive driving of the conductors, notches are cut in the periphery of the core. The magnet limbs are

Digitized by Google

made of soft iron or mild steel, and are very massive to obtain a very powerful magnetic field, and so to reduce the speed of the machines. A machine of this type, of 120-unit capacity, was built for the Aluminium Company, Oldbury, near Birmingham; when tested by Prof. Kennedy it gave an efficiency of 98 per cent. Messrs. Holmes have already many orders for 1894. Among these are a Russian emigrant ship, built by Messrs. R. and W. Hawthorn Leslie and Co., 300 lights, and ventilated throughout with electric fans, having a total capacity of 1,000,000 cubic feet of air per hour; two steam-yachts built by Messrs. Ramage and Ferguson, of Leith, one steamship built by Messrs. Harland and Wolff, Limited, Belfast, one by Messrs. Connell and Co., of Glasgow, 130 lights. Of land installations, those of Messrs. Joshua Smith, Limited, of Manchester, 1,100 lights; the Vulcan Spinning Mill, Bury, 1,060 lights; Messrs. J. Pullar and Sons, Perth, 172 lights (a number of arc lights have also been installed here this year by this firm) have recently been put in hand. At present Messrs. Holmes are fitting up four sugar-mill installations in the West Indies, and have just completed one in Nicaragua, and one in Java, while they have an installation to fit up during 1894 in South America. From the foregoing remarks and figures it will be seen that, even though there has been a general depression of trade during the year, Messrs. Holmes have nevertheless turned out more machines and completed more installations than any previous year.

JOHNSON AND PHILLIPS.—The electric lighting branches of this firm have been well maintained, several of them having been exceptionally busy. Contracts for cables, arc lamps, and accumulators have necessitated an unusual amount of overtime to meet the pressure in these departments. Fresh additions to the buildings and machinery have been put in hand, and are now in progress. It will be remembered that in our last year's summary we referred to the Brooks system of mains, which Messrs. Johnson and Phillips were then on the point of completing for the Chatham and Rochester public street lighting. We have now to report the completion of this contract, and to note the successful working which has attended the installation during the past 12 months. The mains comprise about 12 miles of conductor, and are fitted with junction-boxes, house-service and terminal boxes. This liquid system of insulation has the great advantage over all other systems of being practically imperishable. The cables are placed in heavy wrought-iron tubes, which are then filled with a highly-insulating oil and hermetically sealed, thus securing an insulation which, besides being permanent and reliable, is subject to practically no deterioration. The firm guarantees the perfect working of all mains laid by them on this system for several years. The Brockie-Pell lamp still holds an acknowledged leading position. New shops have been fitted up during the year to cope with the ever-increasing business in them. Hull, Blackpool, Bristol, Portsmouth, Londonderry, Oxford, and Burnley are amongst the towns who have now adopted them for street-lighting. Other places where they are to be found are the Imperial Institute, Blackpool Winter Gardens, Woolwich Arsenal, Bute Docks, and the stations of the London and North-Western and Great Northern Railways. The gardens and Forestry Exhibition at Earl's Court were illuminated by means of these lamps. They have also been shipped in large quantities to Russia, South Africa, New Zealand, and other places abroad. The "D. P." storage batteries have this year been selected out of many competitors for use in several London and provincial central stations; and the increased volume of orders for private installations is the best proof of their popularity in this direction. Cables and wires for electric lighting and other purposes have been demanded at such a rate that work day and night has been compulsory at them for a considerable portion of the year. New and commodious shops are now being erected to relieve the strain. The Perry meter, which the firm has taken up during the year, promises to become an important factor in their business. Already large numbers have been made, and the works are equipped with all necessary plant for their manufacture on a large scale. To make a dynamo so self-regulating as to give not more than two volts variation up or down between 55 and 360 amperes, has been one of the tasks undertaken during the year, and the problem has been solved in a very satisfactory manner, three large multipolar machines of this description having been constructed. Other specialities have been a novel motor-alternator set for use at the University College, London, arranged to work either off the public mains or by means of belt power, and a large multipolar steam dynamo for Her Majesty's Military Electrical School, Chatham. The former is so designed as to demonstrate all phases of alternate-current working. The firm's latest and most successful transformer is commanding a very large sale by reason of its unsurpassed qualities of efficiency. The large ones recently made for Bristol are arranged for the three-wire system.

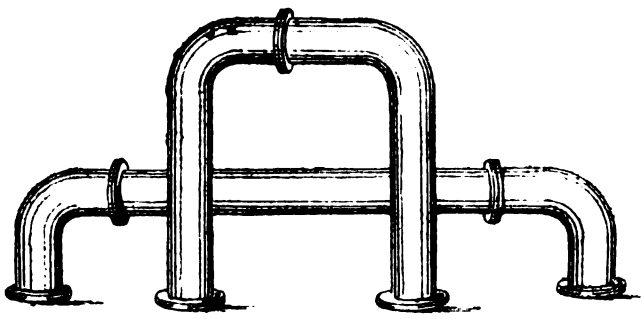
LAURENCE, SCOTT, AND CO. have been exceedingly busy during nearly the whole of the last 12 months, and their works have been taxed to their utmost capacity. They have completely fitted up the Norwich Electricity Company's supply station, and have already had a repeat order for extra plant. The station has several new features; among others, Mr. Scott's patent meter system is adopted, by which it is arranged that supply in the daytime and after eight o'clock at night is charged at half price. The firm hope in the near future to give full particulars of this and other points in the station, and also full particulars and description of the new system of underground mains which is in use at this station, and which is also the invention of Mr. W. H. Scott. It has proved remarkably cheap and convenient, and is giving complete satisfaction. The firm has further been engaged in some large electric transmission of power work, and the ordinary business of the manufacture of dynamos, motors, etc., has also been fairly good.

LIVERPOOL ELECTRIC SUPPLY COMPANY, LIMITED. During the year 1893 the number of lights supplied from the mains of the Liverpool Electric Supply Company has been increased from 20,000 to the equivalent of 25,000 16-c.p. lamps. A new station has been constructed in Lark-lane, Toxteth Park, for the supply of the chief residential district of Liverpool. Among the private installations carried out by the company during the year may be mentioned: Knowsley Hall, for the Earl of Derby; Maer Hall, for F. J. Harrison, Esq.; Haughton Hall, for R. Brocklebank, Esq.

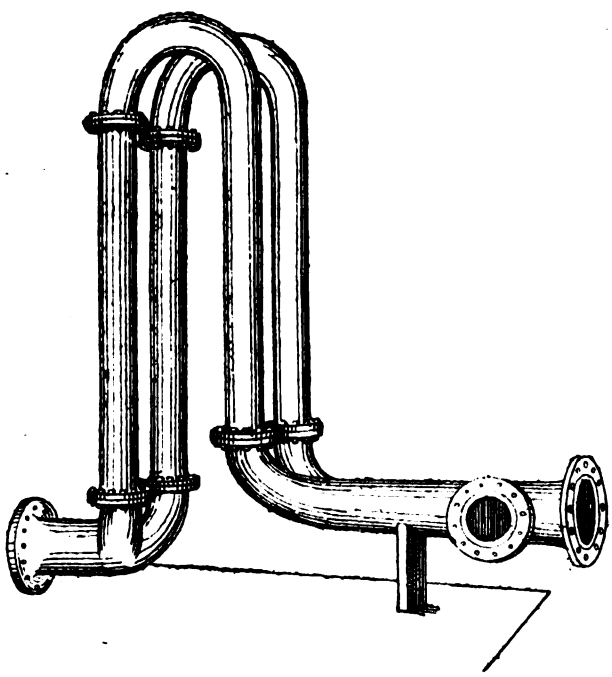
LLOYD AND LLOYD send photographs, from which the accompanying illustrations have been made, which will illustrate the class of work to which they have been devoting attention during the past year. There has been during that time no specially new development of the process, but the works have been running full time the whole year upon

Digitized by Google

elaborate pieces of work in connection with high-pressure steam installations. We may instance the following as examples: As shown on one of the illustrations, a large expansion piece, 10in. bore,



reduced down to 7in., all in steel ¼in. thick. On the other illustration, the long length having bends reduced from 18in. to 14in. diameter, the other two bends being 15in. diameter; 20in. steel tees ¼in. thick tested to 150lb.; bends, 20in. diameter; tubes 12in. diameter, with four and five outlets 6in. and



8in. diameter; all with flanges solid electrically welded on, tested to 600lb. pressure.

A. P. LUNDBERG has been exceptionally busy during the year, having supplied his various specialities to many of the leading electrical contractors, corporations, railway companies, hotels, etc., and in many cases these fittings have been specified in the contracts for important public and private installations. From the large number of orders in hand there is every prospect of an equally successful 1894. There is a continued good demand for the "Unique" switch introduced in January, 1893, and licensees are working the patent in Great Britain, France, Sweden, Austria, and Hungary. The sale of this speciality in its various sizes and adaptations has exceeded anticipation, the total sale of this type of switch having reached 45,000. There is a very fair export trade to the Continent, United States, and the Colonies. Several novelties are being introduced. These include the "Unique" principle adapted for a "pull" switch and also as a "push" switch, alternate pushes or pulls, as the case may be, making or breaking the circuit; as a double-pole switch, main switch, and adapted for use in a lampholder. The "centric" wall socket, which is another speciality, is also going well, and a new type of double-pole cut-out.

The MANCHESTER EDISON COMPANY give the following list of a few installations which they have carried out during the year: John L. Kennedy and Co., 47, Mosley-street, Manchester; H. Verity and Sons, 47, Mosley-street, Manchester; J. E. Waters and Co., 47, Mosley-street, Manchester; C. Lowe and Co., Chemical Works, Reddish; Sir E. Armitage and Sons, Limited, 48, Mosley-street, Manchester; Thos. Parker and Sons, 18, St. Mary's-gate, Manchester; V. B. Sandford, 33, Booth-street, Manchester; W. H. Vaudrey, Esq., J.P., 9, St. James-square, Manchester; Capes, Dunn, and Pilcher, 8, Clarence-street, Albert-square, Manchester; Geo. Macbeth and Son, 19 and 21, King-street, Manchester; T. Seymour Mead and Co., 7, Piccadilly, Manchester; Jas. Dilworth and Son, Pall-mall, Manchester; Llandudno Pier Company, Llandudno; Guardian Society for Protection of Trade, Manchester; Kendal, Milne, and Co., Deansgate, Manchester; Grundy, Kershaw, and Co., 31, Booth-street, Manchester; W. Crum and Co., 43, Portland-street, Manchester; John Bye and Co., Limited, St. Ann's-square, Manchester; the Temple Chambers Company, Brasenose-street, Manchester; the Liverpool and London and Globe Insurance Company, Manchester; Blackpool Winter Gardens, Blackpool; Horrockses, Crewdson, and Co., Limited, Preston and Manchester; Overseer's Office, 46, Fountain-street, Manchester; Literary Philosophical Society, 46, Fountain-street, Manchester; Royal Insurance Company, 69, King-street, Manchester; Manchester Royal Infirmary, Manchester; E. Butterworth and Co., Waterloo-road, Liverpool; J. H. Gartside and Co., Limited, 56, Fountain-street, Manchester; Murch and Everett, Piccadilly, Manchester; Great and Little Bolton Co-operative Society, Bolton; C. Mortimer Booth and Co., 19, Mosley-street, Manchester; Boarshaw Spinning Mills, Middleton; Princes Theatre of Varieties, Reading; John Ashworth, Broadhalgh Mill, near Rochdale; Jones, Crewdson, and Youatt, Norfolk-street, Manchester; S. and J. Utley, St. James-place, Rochdale; Union Bank of Manchester, Limited, Deansgate, Manchester; S. Albrecht and Co., 16, Aytown-street, Manchester; the Bridgeholme Wadding Manufacturing Company, Limited, Chinley; United States Consulate, 9, Mount-street, Manchester; Myrtle, Burt, and Co., 17, Cooper-street, Manchester; Pendleton Co-operative Society, Limited, Broughton-road, Pendleton; Robert H. Kay, Kay's-chambers, Cooper-street, Manchester; *Co-operative News* Office, 90, Corporation-street, Manchester; Hornblow and Brundrett, 58, Cross-street, Manchester; Manchester Society of Chartered Accountants, Manchester; J. Whittaker, Mount Sion Bleachworks, Radcliffe; Jewsbury, Crux, and Gething, Deansgate, Manchester; W. Hollins and Co., Radford, Nottingham; Addleshaw and Warburton, 15, Norfolk-street, Manchester; Eastern Telegraph Company, Limited, 20, Brown-street, Manchester; A. Thompson and Sons, Low Mills, Rochdale; Albion Hotel, Manchester; P. Moir, Crane, and Co., 6, Bank-street, Manchester; Ashworth, Mosley, and Co., 45, Spring-gardens, Manchester; W. Carwell and Co., 47, Mosley-street, Manchester; Union Bank of Manchester, Norfolk-street, Manchester. The company have also many others in hand.

MANCHESTER ELECTRIC LIGHT INSTALLATION.—Although somewhat late in the day, Manchester has made a fair start toward providing its citizens with the latest form of illuminant in electric lighting.

Digitized by Google

Evidence is found of the progress they are making by the condition of the streets through which the mains will pass, and at the same time the motive power and the special apparatus for conducting the current are being prepared. The engines required in generating the electric current are being provided by Galloways, Limited, Manchester. They consist of four distinct compound vertical engines, each having high-pressure cylinder 17in. diameter, low-pressure 34in. diameter, with a stroke of 3ft. The pistons from these cylinders work on to crank-pins placed at each end of a crankshaft, which carries the flywheel acting as a pulley, being turned and crowned for receiving link belt, which transmits the power direct to the dynamo; and, as these dynamos are in close proximity to the engine, jockey pulleys are provided for the purpose of maintaining the requisite tension on the belt. As the engine cranks are at right angles, a receiver between the two cylinders is necessary, and both cylinders, with this receiver, are steam-jacketed—the steam for this jacket being derived from the boilers direct. As is well known, electric lighting requires the most extreme steadiness of turning, in addition to which the speed requires to be varied in accordance with the power the engine is developing. The engines in question are specially adapted to meet these requirements, the variation in speed being effected by Galloways's patent high-speed parabolic governor, specially arranged so that its sensitiveness and speed can be easily altered while the engine is running. The engines are intended to work at a pressure of 120lb. on the square inch, and to develop 400 h.p. each when running at a piston speed of 500ft. per minute. They are also arranged to run faster if required. The steam is condensed, not by the ordinary jet or surface arrangement, but by Korting's ejector condensers placed in close proximity to the engines. These ejectors are supplied from a tank placed over the boiler-house, which will be charged from the canal by means of powerful centrifugal pumps worked by independent engines, the fall of the water condensing the steam, all being carried away without the necessity of an air-pump. The steam required by these engines is furnished by six large boilers, constructed by Galloways, Limited, at their boiler works, Ardwick. These boilers are 30ft. by 8ft., made of steel, to work at 125lb. pressure, and are provided with very complete fittings, including Vicars's mechanical stokers. A very unusual feature in the boiler installation is the duplicated arrangement of the entire ranges of steam and feed pipes; in fact, the duplication is so complete that under no possible combination of circumstances can the whole of the boilers or engines be rendered inoperative. The steam-pipes are of large size, 18in. diameter, and are all of wrought steel, welded with strips double riveted over the weld. These are quite a departure in pipe construction. In addition to the engines as above, Galloways have also made two precisely similar pairs, but of small dimensions, for the Douglas and Laxey Tramway, these engines having cylinders 10in. and 20in. diameter by 1ft. 6in. stroke, with flywheels 9ft. diameter by 12in. wide for taking off the power—namely, 180 h.p. in all. The engines otherwise were exactly similar to those for the Manchester Corporation. The steam for the engines was supplied by two Lancashire boilers 20ft. long by 6ft. diameter of ½in. steel plates, suitable for 125lb. working pressure. The Douglas and Laxey Tramway Company have just let the contract for the continuation of the tramway the whole length, which will require several other pairs of engines similar to those here described.

JAMES MENZIES AND CO.—The wrought-iron tube trade for the past year has been in a very depressed state. Makers generally have been dull, and those who have had much work to do have executed it at an exceedingly low price—if not, indeed, at an actual loss. This being the case, it is somewhat surprising to learn that in spite of this decreased demand for tubes, boiler tubes, and piping of all kinds, either for home or export (the decrease in the latter being confirmed by Board of Trade returns), the firm of James Menzies and Co. actually show an increased production during the last 12 months of about 1,800 tons over the production of the previous 12 months. This is a vast increase in weight, and equal alone to what some of our smaller makers might consider a very considerable production, and shows that this firm will, when trade resumes its usual aspect and our Board of Trade returns their usual increase, take its permanent position as one of the principal, if not the principal, tube-producing firms in the country. They cannot this year trace so much of their demand to tubes for electrical purposes as they could last year, when the City of London Electric Company were in the thick of their work, and were laying down their pipes in such quantities in the City; still, however, a very considerable quantity is being supplied for these purposes, and not the least important are the steel steam-tubes for boiler connections in the new electric stations. Messrs. Menzies report that their Sydney and Melbourne houses are making steady progress, and this notwithstanding the commercial crisis which has existed in these colonies during part of the past year. They find that the tendency on the part of the consumers there is to get as near the source of manufacture as possible, and thus avoid the heavy profits charged by the importer for holding stock against their probable requirements—the consumer in the colonies pays generally, and in wrought-iron tubes particularly has had to pay too heavily for this accommodation. Messrs. Menzies hold fully 150 miles of tubes in stock in their two colonial houses. They report that their home trade has this year increased at a greater ratio than their export trade, and this again is a source of great satisfaction to them, as in the earlier years of this business they acknowledge not having cultivated this branch of their trade as much as they ought to have done.

RONALD A. SCOTT.—The year 1893 has been noteworthy in the annals of the Acton-hill Engineering Works from the fact that they have been, and will in the future be, under the personal management of Mr. Ronald Scott. There has been a steady increase of business, and the orders received have been executed with satisfaction to clients. The switchboard department has been very busy, and has supplied the new type of switchboard to all her Majesty's ships turned out in 1893. A large order for Admiralty projectors and hand-feed search lamps has been executed; also several for the mercantile marine. A large alternating-current projector has been erected on the roof of the Princess's Theatre. This latter work, including the running of 280 yards of heavy cable, was executed in four days. The apparatus for projecting images has been perfected during the past year, and a display was given from the roof of the *Illustrated London News* on the night of the Duke of York's wedding, photographs and names being readily and perfectly projected. The works have also been engaged on orders for heavy water-tight switches and arc lamps. The dynamo department has been exceptionally busy. Amongst others, a large order from the British Government for machines for foreign stations was completed, these

Digitized by Google

latter being required to pass very stringent tests before acceptance. It is noteworthy that amongst the dynamos supplied was one for the Princess Soltykoff. Considering the general condition of trade, Mr. Scott has every reason to congratulate himself on his past year's business, as well as upon the fact that extensive orders are now in hand for dynamo and search-light work, which will keep the works busy for some time to come.

PYKE, HARRIS, AND CO., LIMITED, have during the past year supplied a large number of their well-known inductor alternators, among others, to the following institutions, colleges, etc.: Department of Science and Art, South Kensington; City and Guilds of London Institute, South Kensington; Royal Indian Engineering College, Cooper's-hill, Staines; University Colleges at Nottingham, Liverpool, Leeds, and Bangor: Rugby School; W. H. Preece, Esq., General Post Office; Royal Dockyard, Woolwich; Sir David Salomons, Bart.; Lord Blythswood, Renfrew; Telegraph Manufacturing Company, Limited, Helsby, Warrington; Messrs. Rosling and Matthews, Bradford; Messrs. W. T. Glover and Co., Limited, Manchester; the General Electric Company, Limited, London; and E. Andreoli, Esq., London. They have also brought out, in conjunction with Sir David Salomons, Bart., a small closed magnetic circuit transformer, which has had a very large sale, being applicable both for advertising and decorative purposes, as well as having taken the place, to a great extent, of small induction coils. The whole of the experimental work in connection with Sir David Salomons's patent for improvements in electric heating apparatus has also been carried out by them. They have recently constructed a new continuous-current multipolar dynamo, the field magnet of which is of the same enclosed-coil type that the firm are using in their inductor alternators.

TAYLOR, SMITH, AND CO.—This firm have executed during the year 1893 the principal fittings at Bagshot Park, for his Royal Highness the Duke of Connaught; the Merchant Taylors Hall, London; the Vintners' Hall, London; besides a large number of private residences both in England and Scotland.

TELEGRAPH MANUFACTURING COMPANY report that they have been extremely busy in all departments during 1893. Their vulcanised cables have had a large sale, and they have supplied a large quantity of both high and low pressure mains to various contractors for town work. In their instrument factory they have been favoured with large orders from the Postmaster-General, railway companies, etc., and they have found their sales increase in every department.

W. H. WILLCOX AND CO. have during the year had a great increase in business generally, owing to the progress made by the electrical world in connection with the various installations started in the United Kingdom, and the firm claims a fair share of orders in the way of special cylinder and dynamo oils, also all engineers' sundries. They have also taken up the sole agency for the Penberthy patent injector, also the Farringdon patent pump. These were formerly worked by Messrs. Pontifex and Wood, of Shoe-lane, who have given up this department entirely. This has given them a good addition to general trade. They are building a new warehouse, which will be opened early in the New Year, to enable them to hold a large stock of oil, cotton waste, leather belting, indiarubber and asbestos goods, also the various articles required by electric light installations in the way of stores for the engine-room.

The following is a complete list of applications for provisional orders deposited with the Board of Trade up to the 21st of December, 1893, under the provisions of the Electric Lighting Acts, 1882 to 1890:

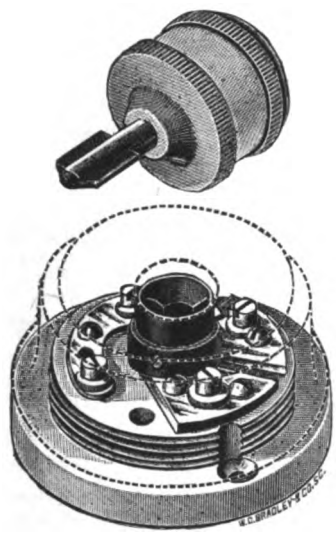
Title of Order and Description of Area.	Name of Promoters.
Aberdare Electric Lighting Order. A portion of the District of the Aberdare Local Board.	J. C. Howell, Limited.
Barrow-in-Furness Corporation Electric Lighting Order. The Borough of Barrow-in-Furness.	The Corporation.
Bedford Electric Lighting Order. The Municipal Borough of Bedford.	Bedford Electric Light Company, Limited.
Birmingham Electric Light and Power Order. A portion of the City of Birmingham.	Birmingham Electric Supply Company, Limited.
Buxton Electric Lighting Order. The Urban Sanitary District of Buxton.	The Local Board.
Chelmsford Electric Lighting Order. The Borough of Chelmsford.	Crompton and Co., Limited.
Chepping Wycombe Electric Lighting Order. The Municipal Borough of Chepping Wycombe.	The Corporation.
Chesterfield (Corporation) Electric Lighting Order. The Borough of Chesterfield.	The Corporation.
Clonmel (Corporation) Electric Lighting Order. The Borough of Clonmel and portions of the District of the Clonmel Union.	The Corporation.
Collier-Marr Moss Side Electric Lighting Order. The Urban Sanitary District of Moss Side.	Collier-Marr Telephone and Electrical Manufacturing Company, Limited.
Grimsby (Corporation) Electric Lighting Order. The Borough of Grimsby.	The Corporation.
Guildford Electric Lighting Order. The Borough of Guildford.	Holloway Electricity Supply Company, Limited.
Harrow Electric Lighting Order. The Urban Sanitary District of Harrow	The Local Board.
Leyton Local Board Electric Lighting Order. The Local Government District of the Leyton Local Board.	The Local Board.
THE COUNTY OF LONDON.	
Crystal Palace District Electric Lighting Order. Portions of: The District of the Beckenham Local Board. The Borough of Croydon. The Parish of Lambeth. The District of the Lewisham District Board of Works, and the Parish of St. Giles, Camberwell.	Crystal Palace District Electric Supply Company, Limited.
Monmouth Electric Lighting Order. The Municipal Borough of Monmouth.	The Corporation.
Oswestry Electric Lighting Order. The Borough of Oswestry.	Oswestry Electric Lighting and Power Company, Limited.
Peterborough Electric Lighting Order. The Municipal Borough of Peterborough.	The Corporation.
Plymouth Corporation Electric Lighting Order. The Borough of Plymouth.	The Corporation.
St. Austell Electric Lighting Order. The District of the St. Austell Local Board.	Veale and Co., Limited.
St. Helens Corporation Electric Lighting Order. The Borough of St. Helens.	The Corporation.
Shropshire Electric Lighting Order. A portion of the Borough of Shrewsbury.	Shropshire Electric Light and Power Company, Limited.
Stirling Electric Lighting Order. The Royal Burgh of Stirling.	Caledonian Electric Supply Company, Limited.
Wakefield Corporation Electric Lighting Order. The City of Wakefield.	The Corporation.
West Hartlepool Electric Lighting Order. The Municipal Borough of West Hartlepool.	The Corporation.
Yeadon Electric Lighting Order. The Urban Sanitary District of Yeadon.	The Local Board.

Digitized by Google

TRADE NOTES AND NOVELTIES.

THE "CENTRIC" WALL SOCKET.

Mr. A. P. Lundberg is putting on the market this wall socket. The plug consists of two segmental rods of spring brass, separated by a backbone of vulcanised fibre running parallel with them, and effectually insulating them from each other; these three component parts are screwed together in the plug, and form a cylinder of ¼in. diameter, with the fibre backbone projecting on each side, the two brass rods forming the contacts of the plug. On the base is screwed two brass contact-plates of ample size, which together form a circular



hole for the reception of the plug. A fibre collar fitting over the projecting ends acts as a shield against short-circuit; a cut-out is also provided. When the plug is inserted, the projecting fibre occupies the space between the contact-plates of the base, and prevents the possibility of any contact being made between them except in the proper manner.

BUSINESS NOTES.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 31st ult. amounted to £619.

Cuba Submarine Telegraph Company.—For the month of December the receipts were £7 more than for the corresponding period of 1892.

Direct Spanish Telegraph Company.—The receipts for the month of December were £197 less than for the corresponding period of 1892.

Ealing.—The Local Government Board have sanctioned the raising by the Ealing Local Board of a loan of £25,000 for electric lighting purposes.

Fined for Assault.—A fine of 10s. has been imposed upon an ingenious individual who a few days ago assaulted an arc lamp trimmer in the City.

West India and Panama Telegraph Company.—The receipts for the two weeks ended December 31 were £143 less than for the corresponding period of 1892.

Western and Brazilian Telegraph Company.—The receipts for the week ended December 22 were £3,446, and for the week ended December 29 were £2,719.

Edinburgh.—The Cleaning and Lighting Committee have resolved to recommend that the line of street from the Tron Church to Jeffrey-street should be lit with the electric light

Hanley.—The Town Council invite tenders for wiring and fittings for the Corporation buildings. Tenders are wanted by the 29th inst. Particulars are given in our advertisement columns.

Brayton Oil-Engine Company, Limited.—This Company has been registered with a capital of £80,000 in £5 shares to acquire certain letters patent for improvements in hydro-carbon engines.

District Messenger Service.—The ordinary general meeting of the District Messenger Service and News Company, Limited, was held on Tuesday at the offices, 50, Lime-street, E.C., Mr. G. Espec J. Manners presiding.

Brighton.—A rental of £25 per annum is to be paid to the Corporation by the directors of the Sea-shore Railway Company. It is proposed to make further additions to the generating plant at the municipal station during the present year.

Compliment to an Electrician.—We note by the Dublin papers that his Excellency the Lord-Lieutenant of Ireland has been pleased to appoint Mr. Angelo Fahie, M.I.E.E., Dublin, to the Commission of the Peace for the city of Dublin.

Treharris.—A public meeting was held on Monday of gas consumers, ratepayers, and others residing in Treharris, when resolutions were passed complaining of the gas supply. Several of the speakers entertained the idea of approaching the Ocean Coal Company to supply the electric light instead of using gas.

Lighting of Newspaper Offices.—The new offices of the Dublin *Daily Express* are lighted by electricity. The engine and dynamo were supplied by Messrs. Edmundson and Son, Capel-street, and the latter is capable of illuminating upwards of 140 lights.

Hull.—The chairman and deputy-chairman of the Sanitary Committee of the Town Council have been appointed to the special committee having under consideration the question of utilising the destructor in connection with the production of electricity.

Messrs. W. T. Glover and Co.—Mr. Henry Edmunds, who since the decease of Mr. W. T. Glover has carried on the business of Messrs. W. T. Glover and Co., of Salford and London, has from the 1st inst. acquired the whole of the business of the Company.

J. G. Statter and Co., Limited.—This Company has been registered with a capital of £20,000 in £10 shares. The object is to acquire as a going concern and carry on the business of electrical and mechanical engineers as hitherto carried on by Mr. J. G. Statter and others at 68, Victoria-street, S.W.

City and South London Railway.—The receipts of the Company for the week ending December 31 were £833, against £966 for the same period last year, or a decrease of £133. The total receipts for the second half-year of 1893 show an increase of £34 over those for the corresponding period of 1892.

Tender Accepted.—The tender has been accepted of Messrs. Cammell and Co., of Sheffield, for the supply and delivery of about 500 tons of steel rails and fishplates, for the Brighton and Rottingdean Sea-shore Electric Tramroad Company, at the price of £4. 2s. 6d. for rails, and at £6. 6s. 9d. per ton for fishplates.

York.—Among the works which will probably engage the attention of the Corporation during the next 12 months, the supply of the electric light takes a foremost place. At the outset the installation will only serve a portion of the centre of the city, but the supply will be extended as required. The estimated cost is £15,000.

Nalder and Harrison.—Mr. N. F. Nalder and Mr. Haydn T. Harrison have entered into partnership for the purpose of carrying on the business hitherto conducted by Mr. N. F. Nalder, and in order to meet the increase of business they are now moving into larger premises at Trafalgar House, Great Newport-street, Charing Cross-road, W.C.

Tenders Invited.—Tenders are invited for lighting and ventilating the police courts at the Salford Town Hall. The plan, specification, and forms of tender may be obtained at the borough engineer's office. Tenders, endorsed "Ventilating Police Courts," must be delivered to Mr. S. Brown, town clerk, Town Hall, Salford, by 11th inst.

Charge of Theft.—On Monday and Tuesday, at the Leeds City Police Court, Mr. Charles Herbert Bent, late manager of the Thomson-Houston Electric Tramway in Leeds, appeared to answer a charge of stealing various sums of money, a suit of clothes, and other articles belonging to the company. Evidence was adduced, and the accused was committed for trial.

Belfast.—The buildings of the central fire brigade station, now completed, comprise engine-house, six-horse stable, hose tower, and dynamo-room on ground floor, etc. The premises are heated by steam and lighted by electricity. The fire-alarms and telephones are received into a test-room at the top of the tower, and conveyed to the indicator in the duty-room.

Manchester.—On Wednesday the Corporation accepted tenders for work connected with the installation of the electric light. It was stated that the mains were to be laid, to begin with, in the thoroughfares from which the largest number of applications for the light had been received. It was expected that some little time would elapse before the installation would pay its way.

Wakefield.—The Corporation, having become dissatisfied with the manner in which the streets have been lighted by the local gas company, recently determined to apply to the Board of Trade for a provisional order authorising them to supply the electric light within the city. The matter has been referred to a committee, who are seeking the necessary information to lay before the Council.

Morley.—The Town Council on Tuesday received the report of the Electric Lighting Committee, which stated that they had carefully considered several schemes sent in for the lighting of the Town Hall and town generally by electricity, and that it was resolved that the committee should be empowered to consult an electrical engineer, and also to visit such electric lighting stations as they deem necessary.

Chichester.—The Lighting Committee of the Town Council a short time ago passed a resolution instructing Messrs. Kincaid, Waller, and Manville to report to the Council as to supplying the city with electric light for a fee of 30 guineas, such fee to be merged in their commission in the event of their employment to carry out the work. This firm is now carrying out the work in a very satisfactory manner.

Dewsbury.—Some time must elapse before the supply of light by the Corporation will be commenced, as although the mains are already laid, the engines, boilers, and dynamos are only now in course of erection. The installation is for the centre of the borough only, and does not include street-lighting. Mr. W. H. Preece is the engineer to the Corporation. The Co-operative Society of Ravensthorpe, near Dewsbury, have decided to introduce the electric light at a cost of £350.

A Joule Fund.—The Mayor of Salford has decided to institute a fund for providing a silver medal annually to commemorate the

Digitized by Google

discoveries of the late Dr. James Prescott Joule, to be competed for by students, or those who had been students, of the Salford Technical School, the City of Manchester Technical School, and the students or associates of the Institute of Civil Engineers under the age of 25 years. the medal to be at the disposal of a committee of the corporations in the order mentioned.

Change of Address.—The headquarters of the consulting practice in civil, mechanical, and metallurgical engineering which Mr. Jeremiah Head has hitherto carried on at Queen's-square, Middlesbrough, has been transferred to 47, Victoria-street, Westminster, S.W. The Middlesbrough office will be retained as a branch. Mr. J. Head has taken into partnership his son, Mr. Archibald Potter Head. M.I.Mech.E., who has for some years been his chief assistant. The practice will in future be conducted under the style of Messrs. Jeremiah Head and Son.

Monmouth.—The Town Council on Monday discussed the revised estimates from the Brush Electrical Engineering Company and Mr. Lailey, C E., as required by the Local Government Board. showing the cost of drainage and electric light separately. The figures showed that if the drainage and electric lighting be carried out separately the initial expenditure would be increased to £19,049, or something over £1,000 more than the original estimate for carrying out the combined scheme. The matter was adjourned to a special meeting, which was to be held yesterday.

Robey and Co., Limited.—As mentioned in our last issue, Messrs. Robey and Co. have been registered as a limited company with a capital of £300,000 The first signatories to the memorandum of association are: Mr. F. Andrew, Lincoln; Mr. T. Bell, Lincoln; Mr E. M. Burton, Lincoln; Mr. F. M. Burton, Highfield, Gainsborough; Mr. H. Mackinder, Mere Hall, near Lincoln; Mr. J. Richardson, South Park, Lincoln; Mr. C. Scorer, Coombe Hurst Lincoln. The first directors are Messrs F Andrew, T. Bell, F M. Burton, S. Lowe, H. Mackinder, and J. Richardson.

Southend.—In a review of the year's work of the Town Council, a local paper states that the Pier Committee in February started to consider the provision of additional electrical plant, and pushed on so rapidly as to recommend the acceptance, at the March Council meeting, of Messrs. Crompton's offer at £1,988. In the summer, Mr. H. J. Dowsing (of Messrs. Crompton and Co.) was allowed to utilise the pier current for the running of a launch at 4d. per Board of Trade unit. The year closes with proposals by the committee for the improvement of the tramway so as to secure the comfort of tram passengers

Bolton.—At a meeting on Wednesday of the Town Council, Mr. Broadbent drew attention to the desirableness of constructing subways for the water and gas mains, as well as for the electric lighting cables. At present the streets were being continually taken up to repair the mains or for other purposes of the kind, and he had been surprised to find how large a sum was spent in this work. Alderman Miles, the chairman of the Gas and Lighting Committee, replied that it would necessitate a large expenditure, and though it might be desirable he could not hold out any hope that the work would be undertaken at present.

Wednesbury.—When the question of gas supply and prices was discussed a few days ago, Mr. Oldbury asked if it would not be a favourable time to enquire into the propriety of lighting the public buildings with electricity. The Mayor said a plan had been perfected of putting oxygen into gas, whereby the lighting power of the latter was increased to the extent of 5½ candles; and if that could be generally done a longer life would be given to gas, and the desire for the introduction of electricity would become less prominent Seeing that Huddersfield had adopted the new system, he did not think that Birmingham would be behind.

English-Made Electric Light Carbons.—Hitherto all the electric light carbons consumed in this country have been imported from the Continent and the United States. Now, however, the English Electric Carbon Company, Limited, of the Electric Carbon Works, Brymbo, near Wrexham, have started a factory in that town on the most approved continental lines. The company have determined, for the present at any rate, only to produce carbons of the very highest quality, at least equal to the best continental brands, and they believe that the use by consumers of inferior American qualities of carbon is the cause of the notion in some quarters that an arc lamp can only work by fits and starts.

Coventry.—The Town Council have confirmed the minutes of the General Works Committee, from which it appeared that the town clerk and the city surveyor had attended at the offices of the Board of Trade, and had an interview with Sir Courtenay Boyle and Mr. W. S. Graff Baker and his solicitor. The committee had ordered that subject to Mr. Graff Baker and the Coventry Electric Tramways, Limited, entering into an agreement. that the statement and certificate of cost mentioned in Clause 2 of the agreement of 17th April last, between the Corporation and Mr. Baker, shall take account only of money actually expended on the tramways and their equipment prior to their transfer to the company, the opposition to the transfer be withdrawn.

Traction at Newcastle.—A special meeting of the Tramways Committee of the Newcastle Corporation was held on Wednesday to consider the advisability of issuing to the Council an informatory report on the proposed alteration in the tramway system of Newcastle It may be remembered that in May last Mr. Morton brought forward a motion in the Council that the committee be empowered to enquire into the relative merits of steam, cable, electricity, and other methods of working various tramway systems. The committee, on Wednesday, after fully considering the matter, decided to send a report to the Council, detailing all they have seen, and stating that they are prepared to recommend the adoption of the cable system in Newcastle at an early date.

Epstein Accumulators—The Epstein Accumulator Company, Limited, has just completed the installation of a large battery for the Hunts Bank lighting station of the Lancashire and Yorkshire Railway at Manchester, consisting of 60 of their type R 11 cells, capable of discharging up to 250 amperes. The company are extremely busy with a number of orders for important batteries, amongst which is one of 120 cells, type R 13, up to 270 amperes discharge, for the Lancaster electric lighting station, and another of 54 cells, type R 25, discharge up to 540 amperes, for Messrs. Barclay and Co., Regent-street, as well as a battery of the traction type for the War Office.

Guildford.—The Holloway Electricity Company have received consent from the Town Council to their application to the Board of Trade for a provisional order. The conditions are said to be so unreasonable that unless they are modified, or the Board of Trade dispenses entirely with the consent of the authority, the project will have to be abandoned. The Council ask, in effect, that a clause shall be inserted in the provisional order giving them power, after the expiration of 10 years from the granting of the order, to purchase the undertaking at whatever price the plant might be valued. No allowance is to be made for compulsory purchase or "goodwill," or for the money sunk in preliminary expenses and in placing the undertaking upon a sound footing.

Companies Liquidated or Converted during 1893.—Among the companies that have gone into voluntary liquidation, or have been continued under another form during the past year, are the following: The Telephone Company of Austria, the Electrical Supplies and Fittings Company, and the London Lighting and Engineering Company. The companies wound up voluntarily with a view to reconstruction, amalgamation, or some other form of existence, included the Foreign Electric Date and Time Stamp Company, the Boy Messengers and Electric Call Company, and the Electric Construction Corporation. Elmore's French Patent Copper Depositing Company and the "Medical Battery" Company were ordered to be wound up by order of the Court.

Amalgamation of Engineering Works.—Messrs. John Wilson and Son, of the Vulcan Works, Johnstone, advise us that they have purchased all the patent rights, drawings, patterns, etc., of the late firm of Messrs. J. and W. Weems, hydraulic and general engineers, Perseverance Ironworks, Johnstone. They have also purchased the works, tools, plant, drawings, patterns, etc., of the late firm of Messrs. Wm. Robertson and Co., machine tool makers, Floor-street Works, Johnstone. Messrs. Wilson and Son have combined the two businesses, and will carry same on at the Vulcan Works, Johnstone, executing orders for the various specialities of the two firms; and they have placed these works under the supervision of Mr. Alexander Wylie, who for the past 30 years has been connected with the late firm of Messrs. J. and W. Weems.

Government Contracts and Foreign Labour.—It was recently stated that, though thousands of British workmen were starving in consequence of scarcity of employment, the General Post Office had instructed "Siemens, of Berlin," to put down a cable between Liverpool and New York at a cost of £2,000,000. A letter has been received by a correspondent, who drew Mr. Arnold Morley's attention to the subject. The letter stated that no order for an Atlantic cable had been given by the Post Office Department. The cables between this country and America belong to private companies, and it is understood that one of the companies—viz., the Commercial Cable Company (an American company)—is about to lay an additional cable. The order for this cable has, it is believed, been given to Messrs. Siemens and Co., whose works are at Charlton, near Woolwich.

Halifax.—The Corporation have, in consequence of the electric light supply by a private company having been suspended, been forced to take action in providing electricity works, which is being done under the auspices of the Gasworks Committee. The Corporation applied in August last for the sanction of the Local Government Board to borrow £30,000 for electric lighting. The scheme has been prepared by Mr. Wilmshurst, the Corporation's electrical engineer. The central station is to be at the gasworks. The Corporation will lay mains throughout the principal streets sufficient to supply 30,000 lights. but the plant in the first instance will only provide for 10,000. There will be sub-stations at the Town Hall and in George street, and the cables will be laid under the footpaths. The estimated cost of these works is £26,100, which does not include street-lighting.

Bradford.—A large number of replies have been received by Mr. W. Glossop to his circular, referred to in our issue of the 22nd ult., and addressed to the ratepayers of Heaton, asking if the recipients were in favour of the Bradford Corporation supplying electricity in place of gas at Heaton, which is now served by the Shipley Gas Company. The general effect of the answers is favourable. Mr. Glossop's idea is to get a separate installation for Heaton and Manningham, and he has hope that his object will be attained. He has obtained particulars respecting the price of gas and the electric light since they were introduced into Bradford. The Corporation acquired the works of the old gas company on July 1, 1871, when the price of gas was 3s. The price of electricity on September 20, 1889, when it was first introduced by the Corporation, was 6d. per Board of Trade unit, and the present charge is 5d.

Lighting of Engineering Works.—The shareholders of Messrs. Dixon and Man, Limited, Steel and Wagon Works, Armadale, visited the works last week. The works have recently been almost entirely reconstructed, and the electric light introduced into the engineering, bridge-building, and steel toolmaking departments

Digitized by Google

The installations were carried out by Messrs. Walter Dixon and Co., of Glasgow. The plant consists of a Tyne dynamo, constructed to give an output of 7,475 watts, and driven direct by a separate engine. The whole of the works, including the saw mill, machine shop, truck shop, smith's shop, stores and paint shop, together with the offices and the Board-room, are fitted up and lit with incandescent lights of various candle-powers, amounting in all to 66 lamps of 16 c.p. and eight lamps of 50 c.p., and various other groups of lights where most required. In the bridge-building shop and in the yard three arc lamps of 2,000 c.p. have been placed.

Lighting of Co-operative Stores.—The Leicester Co-operative Society have had their extensive premises at the corner of High-street and Union-street fitted with the electric light. Messrs. Scott, Mountain, and Co., of Newcastle-upon-Tyne, have carried out the installation. The plant comprises a Robey gas-engine of 16 brake horse-power, provided with a self-starter and an extra large flywheel and a Tyne 18-unit dynamo. There are 320 lights in the building, which is divided into five circuits. There is a large arc lamp at the top of the building. Near the dynamo-house is a room for the storage cells, of which there are 55. At the formal ceremony in connection with the starting of the installation, the Chairman said that co-operators generally were on the look-out for more light—light to assist them in developing their production, and also in distributing what they produced. They had tried various methods of lighting their premises, but had now arrived at the brightest light—namely, electricity.

Pupils' Dinner.—The past and present pupils connected with the Manchester branch of Woodhouse and Rawson United, Limited, held their first annual dinner on Wednesday, December 20, at the Grosvenor Hotel in that city, when upwards of 20 past and present pupils and friends sat down to dinner. Mr. H. C. Crews, the local electrician, occupied the chair. After dinner the evening was spent in getting through a varied programme of songs, etc., contributed by the following gentlemen: Messrs. Crews, Handford, Dewar, Gardam, Payne, Jackson, Twemlow, Wilkinson, A. B. Pilling, and W. Wilkinson, Messrs. Lea and F. S. Pilling accompanying. During the evening the local manager, Mr. Bertram Thomas (who had been prevented by business from being earlier), put in an appearance and contributed not a little to the enjoyment of the evening, his rendering of a well-known song being greeted on its conclusion by those present singing "For he's a jolly good fellow." In reply Mr. Thomas made a happy little speech, in the course of which he thanked the company for their kindness. Shortly afterwards a most enjoyable evening was brought to a close by singing "Auld Lang Syne."

Birmingham.—The annual conversazione of the Birmingham and Midland Institute will take place on Tuesday, Wednesday, and Thursday next at the Town Hall and the institute. The whole of the rooms used in both buildings for the conversazione will be lighted by the Birmingham Electric Supply Company, who will also arrange in the institute a loan exhibition of electrical appliances. The exhibition will include fittings illustrating the application of electricity to lighting purposes, two rooms being fitted as examples, one as a drawing-room by Messrs. F. and C. Osler, and the other as a dining-room, by Messrs. Evered and Co., Limited A complete set of appliances for cooking and heating purposes will be exhibited, and practical demonstrations will be given by an experienced cook. The apparatus for these purposes will be supplied by Messrs. Crompton and Co. A number of small motors will be shown working in connection with various types of light machinery for manufacturing and domestic purposes The exhibition will also include specimens of various arc and incandescent lamps in general use, measuring instruments, and specimens of the Birmingham Electric Supply Company's system of underground mains. Telephones in connection with public performances in distant towns will be again exhibited by the National Telephone Company, Limited.

Railway Station Lighting.—The Great Northern Railway Company have recently established a system of electric lighting at their goods yards and warehouses at Wellington-street and Wellington Bridge, Leeds. The supply is obtained from the Yorkhouse House-to-House Electricity Company, Whitehall-road, where the pressure of the current generated is 2,000 volts, and is transformed down at a sub-station on the premises of the railway company in Wellington-street, whence, by means of a switchboard, it is distributed throughout the warehouses and goods yards, the cables being run underground through the yards. There are about 30 Brockie-Pell 2 000-c.p. arc lamps. Twenty of these lamps (in hexagonal lanterns) are placed in the yards, and are fixed either on iron columns or on brackets, varying in height from 22ft. to 26ft. Inside the warehouses the lamps are of the same type as those outside, but are covered by opalescent globes, and are suspended from the girders carrying the upper floor. The lower floor of the granary in Wellington-street is lighted by five incandescent lamps of 100 c.p. each. The cable, which is about two miles in length, was supplied by Messrs. Siemens Bros., of Woolwich, and the lamps, lanterns, transformers, etc., by Messrs. Johnson and Phillips, Old Charlton, Kent, the whole being installed by the Great Northern Company's staff. The effect of this installation is to enable the work in the goods yards and warehouses to be carried on with much more expedition, and with greater facility and safety.

Sutton.—The Local Board have considered a report of the General Purposes Committee, who stated that Mr. Cave and other ratepayers would not tender for electric lighting, but that if no tenders were received they would be prepared to take the matter up. The committee recommended that tenders for electric lighting should be advertised for in the form settled by the committee, and that the clerk be instructed to forward to all persons who have applied to the Board as to working the electric light a copy of the advertisement in answer to such applications. The chairman remarked that if they invited the public to tender for certain things they must make themselves tolerably safe with regard to the obligations they should put upon them in the event of their tender being accepted. Mr. Price was in favour of the matter being referred back to the committee to draw up a specification to be approved by the Board. The Chairman said that one important matter would affect all the persons who tendered, and it was whether the local authority would have the streets lighted with electricity. Mr. Overton said that was one of the last things they thought of. Mr. Wellington said that with reference to the period during which the Board transferred their powers, he thought 14 years would be better than 21, but the committee came to the conclusion that no one would tender for less than 21 years. The Board should have the option at the expiration of 21 years and every subsequent seven years to purchase the system of electric lighting. Subsequently the matter was again referred to the committee.

Northern Society of Electrical Engineers.—Some correspondents write: "We are much surprised at the element elected on the council of this society. If it were termed the 'Manchester Society of Electrical Engineers,' instead of the 'Northern,' we could understand it, as by far the greater portion of the council are manufacturers and contractors in the city of Manchester. We look in vain for a railway telegraph engineer, or a Post Office telegraph engineer, or a National Telephone Company's engineer, and therefore the inference is that telegraphy and telephony are branches of electricity too insignificant to be represented on the council, and that there are no electrical engineers in the North of England except those resident in Manchester. The names of those men who have done good electrical service in years gone past are conspicuous by their absence. We look in vain for the names of Fletcher, Langdon, Hampson, Jackson, Stockdale, Hewitt, Clay, Parker, F. F. Bennett, Vaudrey, Doherty, Macfee, and Holmes—men who have been connected with electrical industry for 15 or 20 years past. On the other hand, we are brought face to face with the fact that some of those appointed on the council are not electrical engineers at all, and cannot by any possible exaggeration be termed such. We need hardly say that if this society is to be conducted on these lines, the result will be disaster, as no electrical engineer of repute would care to be a member or to take any part in the proceedings when the concern is presided over and managed by so unrepresentative a body. To say the least, the selection of the council has been too hurried, and time should have elapsed to allow a larger number of members to join, and then the nominations and voting should have taken place. It would also have been a wise course to pursue to have allowed the representatives of purely electric lighting to be represented on the council by six members, the remaining six to be drawn from the capable ranks of the telephone and telegraph engineers. We consider that, to justify its title, members of the council should have been drawn from various towns in the North, and not all, or nearly all, from one town. Manchester, at the outside, should only have two members allowed to sit, Liverpool two, Birmingham two, Leeds, Bradford, Sheffield, Newcastle, Preston, and Bolton one each."

Lighting of Chelmsford.—At the monthly meeting of the Town Council last week, matters relating to the lighting of the borough by electricity were again discussed. It will be remembered that the whole Council, sitting as an open committee, have recently held two meetings for the express object of dealing with and settling these questions, and their report was Wednesday last week brought up by the town clerk. The Mayor proposed, and Councillor Whitmore seconded, the adoption of the first clause of the report, which related to the question of overhead wires, and which proposed to leave the matter entirely in the hands of the Board of Trade. Councillor G. W. Taylor moved the following as an addition to this clause: "But the Council trust the Board of Trade will, as far as practicable, meet the wishes of the electric lighting company in the matter." He said that Mr. J. F. Albright, one of the managing directors of Messrs. Crompton and Co., and Mr. A. H. Pott were invited to attend a meeting of the Lighting Committee, and the committee virtually and tacitly agreed to send a resolution to the Board of Trade assisting Messrs. Crompton and Co. in the matter of allowing certain wires to remain overhead as far as they could. It might be asked what was the *quid pro quo*? It was this. Mr. Albright consented that if the Town Council would pass such a resolution and send it to the Board of Trade they would reduce the price of the electric light to private consumers from 8d. per unit to 6½d., with a discount of a halfpenny for cash payments within a month of the account being delivered. If the Council simply passed a resolution leaving the whole matter to the Board of Trade, they would not be treating Messrs. Crompton and Co. fairly and reasonably in the matter. In honour to Messrs. Crompton and Co., he asked them to agree to the addition he proposed. Councillor Tanner seconded the additional clause. Councillor Britton supported Councillor Taylor's addition, because he thought they should do all possible to ease a firm who had laid down so many thousands of pounds in the borough, especially as the borough had received from it, during a time of severe depression in agriculture, a very great stimulus. On a division the motion for the adoption of the additional clause was lost. The second clause in the committee's report, which related to the renewing of the contract for the lighting of the streets by electricity, was passed without comment. The third and last clause,

Digitized by Google

which dealt with Messrs. Crompton and Co.'s application to the Board of Trade for a provisional order, was then considered. After considerable discussion, the recommendation of the committee, as given in our last issue, was carried. Authority was given to the town clerk to give the necessary notices to the Board of Trade and others interested as to the alteration required by the Council in Clause 80 of the provisional order. It was subsequently resolved to instruct the Lighting Committee to consider the advisability of removing the old gas standards.

Glasgow.—On Tuesday, at a meeting of the Clyde Navigation Trust, the minutes of the Committee of Works were submitted. They contained a report by the sub-committee on hydraulic appliances for Cessnock Docks. The committee having visited various ports where there were large installations of hydraulic plant, reported regarding these, and recommended as follows: (1) That the trustees be asked to adopt a scheme of electric lighting for Cessnock Dock. (2) That designs and tenders be taken for an electric power installation sufficient to light the whole dock, and work, say, nine electric cranes—viz., three for each of the three berths on south quay of north basin, the electric light in the first case being supplied to this portion of the dock. If the cranes are successful, then more boilers and dynamos would be added from time to time as more cranes on the remaining quays were required. Should the cranes not be successful, the contractor should be taken bound to remove them completely to make way for hydraulic cranes to be provided by the trustees; but the electric power would remain for the lighting of the dock, and the surplus power could be applied to lighting some of the quays along the river, or for other purposes. The electrical engineers met with are so confident of success that the committee anticipates no difficulty in obtaining a guarantee of the nature indicated, to guard against the cranes proving a failure and being left on the trustees' hands. (3) That a more liberal supply of cranes should be provided than was at first proposed, and that three cargo cranes should be allowed instead of two to each berth devoted to merchandise. (4) That to give contractors an idea of what the requirements may be, so that they may be enabled to make their calculations, it might be assumed that there would be in the portion of the dock to be dealt with 16 berths for merchandise, each requiring three 35cwt. cranes, giving 48 of these cranes; and that the south quay of dock, consisting of five berths, might be devoted to coal and minerals, and be equipped with two 20-ton coaling cranes and nine 5-ton mineral cranes. (5) That the type of movable crane carriage to be adopted should be what may be called the one-leg and one-arm type, consisting of an elevated platform, supported by the leg resting on wheels running on rails laid along cope of quay, and the arm resting on wheels running on rails laid on or under platform for upper floor in case of a two-storey shed, or on rails at level of or under eave of roof in the case of a single-storey shed. Next to a crane placed upon roof of shed, as at Liverpool, this is the arrangement which would give freest scope for traffic and width for laying down a line of rails between cope of quay and front of shed, and is the plan adopted at Hamburg for steam, electric, and hand cranes, at Southampton for the electric cranes, at Bristol at latest two-storey shed, and it can be seen at the James Watt Dock, Greenock. (6) That the ordinary cargo crane to be placed on a carriage of this description should be capable, as above stated, of dealing with maximum loads of, say, 35cwt. Mr. Richmond moved the adoption of the minutes, with the understanding that the report with regard to crane appliances should not be discussed till next meeting. The minutes, on this understanding, were confirmed.

The Utilisation of Town Refuse.—Mr. C. Rawson has written to a Bradford paper on this subject, and in particular to the statements made by Mr. G. Priestley, and to which reference was made in our issue of the 22nd ult. Mr. Priestley had stated that "Bradford refuse will evaporate 4lb. to 5lb. of water from every pound of refuse thrown into Livet's furnaces, which is considered a good result." To this Mr. Rawson replies as follows: "As one who has had a considerable amount of experience in the burning of town's refuse, both in the laboratory and on the large scale, I can fully endorse the statement that such a result is a good one—an exceedingly good one—especially as town's refuse does not theoretically contain so much heating power. I have always believed in the conservation of energy, and that one is unable to destroy or create matter. It would be highly interesting to know how these fundamental principles have been overcome in Livet's steam generator. I could understand the excellent results if 'a little coal tar and smudge' were mixed with the refuse. Town's refuse, as I have recently shown in a paper read before the Society of Chemical Industry at the Yorkshire College, contains a great amount of combustible matter, but it is not likely that any good will be done by overestimating the amount. As Mr. Priestley does not give details of tests requested by a Mr. Leach, perhaps you will allow me to supply a few particulars. I was present when a quantity of refuse, which had been dried in Smithson's apparatus, was used as fuel. The composition of the crude refuse was as follows:

Coarse portion	34·67 per cent.
Fine portion	27·48 ,,
Rags, paper, etc.	5·76 ,,
Metal, glass, pot, etc.	·84 ,,
Water (evaporated in apparatus)	31·25 ,,
	100·00

6,082lb. of the coarse portion, burned in Livet's furnaces, evaporated 17,410lb. of water. One pound, therefore, evaporated 2·86lb., equivalent to 0·99lb. of water, from 1lb. of crude refuse; but on putting the crude wet refuse into the furnaces, heat would be abstracted in driving off the 31 per cent. of water which it contained. From every pound of refuse 0·31lb. of water would have to be evaporated in the furnace without producing any useful work. This quantity must, therefore, be subtracted from the heating power of the dry material. On the other hand, the fine portion (27·48 per cent.) has an evaporative power equal to about one-half of that of the coarse portion. Making both these allowances, I find that 1lb. of crude refuse thrown into Livet's furnaces evaporates 1·06lb. of water. Of course, if we calculate on the amount of combustible matter present the results are very different. The average amount of combustible matter in a considerable number of samples of refuse which I have analysed is 24 per cent. One pound of combustible matter, according to the above figures, has, therefore, an evaporative power of 4·42lb., but in order to obtain this result rather more than 4lb. (not 1lb.) of refuse must be thrown into Livet's furnaces. In the above calculations I have assumed that refuse thrown on to the fire in its crude state would produce proportionately as much heat as when it has been previously dried, but the attainment of such a result is doubtful. However, perhaps Mr. Priestley will furnish details of tests of burning the crude wet refuse. If 4lb. to 5lb. of water can be evaporated from every pound of town's refuse put direct into a boiler furnace provided with movable grate-bars, it seems strange that the problem of dealing economically with the material was not solved long ago. Providing such a result could be obtained, the product after drying would possess a greater heating power than that which is usually obtained from good average coal."

The Tramway Question at Leeds.—On Wednesday, at a meeting of the Town Council, Alderman Sir Edwin Gaunt, on its being proposed that the minutes of the Highway Committee be approved, complained that more information had not been given as to what was being done with respect to the tramways. He was particularly anxious to know what course was to be adopted as to the working of the lines, whether they were to be let to a company or the Corporation intended to carry on the undertaking itself. With respect to the system of traction to be adopted, he was informed that in Birmingham there was a loss of 2¼d. per mile run last year by the electric system, whereas there was a profit of 6d. per mile by the cable system. He should perhaps be told that in the case of the electric system in Birmingham accumulators were used, and that these were wasteful. That was so; but, in his opinion, what they had seen in South Staffordshire would be equally wasteful. In conclusion, Alderman Sir E. Gaunt expressed himself strongly in favour of letting the tramways to a company. Alderman Ward was of opinion that if they could let the tramways upon such favourable terms as had been obtained by the Edinburgh Corporation, there would be no hesitation as to what should be done. He did not think the Corporation should take upon itself the working of the tramways. As to the system of traction the choice seemed to lie between electricity and the cable. With regard to the cable system in Birmingham, which was said to have been so successful, it had to be remembered that in that case there was a three minutes' service in a densely-populated part of the city; whereas, in the case of the electric system, that was only an experimental line, on the accumulator principle, which was now considered "out of court" on account of its heavy cost, and the population of the district was comparatively small. It would obviously be necessary to decide what system of traction they would adopt, before they set about relaying the track. The Highways Committee were fully alive to the importance of the matter, and he undertook to promise that the Council should be taken fully into their confidence. Mr. Loe agreed with Alderman Gaunt. The Corporation had as much on their hands as they could manage. He incidentally observed that he greatly admired the way in which the Roundhay Park electric cars were worked. Alderman Scarr also approved of the lines being let. He was convinced that if the Corporation attempted to manage the tramways, the result would be a fiasco. He hoped they would seek to imitate Edinburgh in the matter. He was persuaded that competition for the tramways of the city would not be lacking. If they could get a rental of £13,000, that would be equal to a rate of 2d. Mr. Battle held that a corporation could not work such a concern as well as a private company. Alderman Firth (chairman of the Highways Committee) replied that it had never been the intention of the Council to take any responsibility with regard to the selection of a system of traction. A sub-committee had simply been appointed to look after the working of the lines until they were in fit condition to be let, and to enquire and recommend as to the best system of traction. Their recommendation would come before the Highways Committee, but the Council would have to finally decide and take the whole of the responsibility. The committee realised the importance of the work, and were doing what they could to serve the city, and he hoped that time would be afforded them to make the necessary investigation. Leeds could show the best specimen of motive power to be found in the country; but whether the citizens would approve of that system being applied to the whole borough was another question. With respect to the Corporation working the tramways, so far as he was at present informed, he should be no party to it. The less labour the Corporation employed the better it would be for the citizens. The course he favoured was to ultimately let the lines to some company that would meet the requirements of the Corporation as to workmen's cars and the service generally, including the working of any extensions that might be deemed necessary from time to time. The minutes of the Highways Committee were approved.

The "Medical Battery" Company, Limited.—The winding-up order against this Company was made last November, and on

Digitized by Google

Tuesday Mr. C. J. Stewart, official receiver, issued the usual summary of accounts, together with his observations upon the case. It appears therefrom that in November, 1881, a company with a capital of £15,000 was registered, under the title of the Pall Mall Electric Association, Limited to acquire the business of Mr. C. B. Harness. In March, 1885, the first "Medical Battery" Company, Limited, was incorporated, with a capital of £100,000, to acquire the business of the Pall Mall Electric Association, then carried on at 21, Holborn-viaduct, and a separate business opened by Mr. Harness in 1884 at 205, Regent-street, for the sale of electric and medical appliances. In the year 1889, it being thought advisable to treat patients suffering from various forms of disease, and as the articles of the first "Medical Battery" Company did not provide for such an extension of business, that company was wound up voluntarily, and the new company took over its entire undertaking. The liquidator of the old company was Mr. Harness. Soon after the formation of the Company the lease of the premises terminated, and as the landlord refused to accept the Company as a tenant, Mr. Harness took a fresh lease in his own name, at a rental of £750 per annum, subsequently giving the Company a sub-lease at an annual rental of £1,000. It was resolved to issue debentures for £10,000 in March, 1893, of which £6,000 were offered for subscription to the shareholders, who, however, made at first but small response to the offer. The total issue is £8,150, of which Mr. Harness holds £3,000 and Mr. Graff £1,000. At a general meeting of shareholders on October 14, 1893, it was resolved to increase the capital of the Company to £200,000 by the issue of 20,000 preference shares of £5 each. A prospectus was accordingly published on October 18, 1893, and was advertised in various papers. On the following day and during the ensuing 10 days articles appeared in a London evening paper strongly animadverting upon the Company and Mr. Harness. The advertisement of the prospectus was at once withdrawn, and the money received on application for preference shares was returned. On November 3 it was decided to wind up the Company. By the articles of association Mr. Harness was appointed president and managing director at a salary of £1,000 per annum. At a general meeting of the shareholders on January 22, 1891, it was decided that this sum should be increased to £2,000 per annum. A dividend of 4½ per cent. was paid to the shareholders in 1889, and dividends of 10 per cent. per annum were paid during 1890, 1891, and 1892, the total amount being £34,500. Fees amounting to £1,650 were paid during the same period to the directors. The accounts filed under the winding-up order show total liabilities £23.916, of which £19,780 is expected to rank for dividend. The assets, valued at £4,242, are claimed by the debenture-holders, and the account with the contributories discloses a total deficiency of £119,780. The largest shareholders in the Company are: Mrs. Harness, £38,205; Mr. Harness, £7,225; Major Elers, £14,205; Mrs. Elers, £5,250; and Mr. McRae, £5,000. The deficiency account shows that the trading of the Company resulted in a gross profit of £274,260. and that the expenses of carrying on the business amounted to £240,667. Included in the latter amount is a sum of £170,878 paid for advertising from 1889 to 1893. Law costs (£6,588) appear to have been incurred in respect of the before-mentioned litigation, and a further sum of £861 was expended in experiments directed to prove that the chargee brought by the papers against the Company's appliances were contrary to fact. The failure of the Company is attributed by Mr. Harness to the unfavourable articles and the consequent litigation, also to the later articles in the London evening paper, which induced a number of claims to be made for the return of money paid for goods supplied by the Company, and made it evident that the preference shares would not be taken up by the public.

Electric Lighting in Carlisle.—Very little has been done in this city towards adopting electricity for lighting purposes In the case of public lighting the Corporation obtained a provisional order in 1882 (this order was revoked July 1, 1892) for lighting the town by electricity, but no practical steps were taken under it, although several parties approached the Corporation with a view to get the powers transferred. The Corporation, however, did not see their way either to undertake public lighting by electricity or to assist others in doing so. With regard to private electric lighting, the most noteworthy installation is that in the Public Library, Museum and School of Science and Art Buildings, Tullie House. The buildings are lighted throughout by electricity, gas only being used in part of the basement. The generating plant is situated in the basement in a room specially designed for the purpose. This room contains the engines, dynamos, switchboard, and other necessary appliances, including also one of the water-tanks, while in the meter-room adjoining are placed two 150 light gas-meters and the second water-tank. Adjoining the dynamo-room is a chamber in which are placed the exhaust and silencing boxes for the gas-engines. The plant consists of two Tangye horizontal gas-engines of the most recent type and construction, combining all the latest improvements for electric lighting work. Each engine is of 16 nominal horse-power, and is guaranteed to give 35 actual brake horse-power; they are fitted with Pinkney's patent self-starter, whereby one man is capable of starting an engine. Every precaution has been adopted in order to ensure steady running and to prevent any fluctuation in the lights. With this object in view, in addition to extra heavy flywheels having been provided, the driving pulleys of the engines are made to fit loose on to the shafts, but are connected to the flywheels by means of spiral springs, in order to further deaden the shock due to the explosions in the cylinders. The exhaust from each engine is conducted through specially constructed exhaust silencing-boxes—two to each engine. After passing through these boxes the exhaust gases are conducted by means of two 4½in. internal diameter cast-iron pipes to the roof. Each engine is supplied with a water-tank having a holding capacity of 150 cubic feet for the purpose of circulating water round the cylinder of the engine, and keeping the same sufficiently cool for the purposes of lubrication. Each engine is placed upon and bolted down to a solid bed of cement concrete, 4ft. in depth, so as to ensure a good and firm foundation. The power is transmitted from the engines to the dynamos by means of 6in. strong cotton belting. The dynamos were made and supplied by Messrs. Latimer Clark. Muirhead, and Co, of London. Each dynamo is capable of maintaining 350 16-c.p. incandescent lamps. They are shunt-wound, having an E.M.F. of 105 volts, and giving a current of 200 amperes when running at 600 revolutions per minute. These machines rest on solid beds of concrete 3ft. in depth; to the concrete are bolted three slide rails, and upon these the dynamos rest, being fitted with movable brackets and adjusting bolts for the purpose of tightening up the belt when necessary. The field magnets are wound on separate wrought-iron cores, so that they can easily be removed if necessary. The armatures are interchangeable, and adequate provision is made for ventilation in order to avoid undue heating. There are four copper gauze brushes, having proper provision for adjustment and also for ensuring the necessary amount of pressure when running. The wiring is divided into seven circuits, and is upon the multiple main system—*i.e.*, separate pairs of mains run from the main switch-board to the several parts of the building, where the subsidiary switchboards are placed, and from these latter the wires are taken to the lamps according to the several sub-circuits in each room. All the wires are of copper, tinned and stranded, thoroughly insulated by means of indiarubber, tape-braided. They have been proportioned at a maximum current capacity of 660 amperes per square inch of sectional area, and are laid throughout in grooved wooden casings. The main circuits, sub-circuits, and single lamps or cluster of lamps, are protected in all cases by means of safety fuses proportioned to the current which they have to carry, these fuses in every case being easy of access for purposes of inspection and renovation. The lamps, of which there are altogether some 434, equivalent to 558 of 16 c.p. each, are of the Edison-Swan type, and vary from 8 c.p. to 50 c.p., according to the amount of light required in the different positions in which they are placed. Those of 8 c.p. are used in the subway, cart-dock, lavatories, and in those places where much light is not required, while in rooms where a better light is necessary lamps of 16 c.p., 32 c.p., and 50 c.p. have been fixed. In many instances it has been found advantageous to make clusters of several lamps, of 16 c.p. or 32 c.p. Opal shades of a plain but effective pattern have been used throughout, except in places where the light is required to shine on to some particular object as in the picture galleries, in which case side reflectors have been adopted In the library and main entrances brass electroliers have been fixed which, with their ornamental shades, give a very pretty effect. The main switch-board is placed in a convenient position in the dynamo-room. It is composed of a slate base 1¼in. thick, enamelled on face and fitted in a wooden frame. This slate measures 5ft. by 3ft. On this are fixed the switches to the seven main circuits. On the lower part of this switchboard are fixed the two main switches from the dynamos, and between these principal switches are placed two ammeters. Each switch is composed of brass connecting pieces with vulcanite handles. On this board are also fixed the safety fuses to each of the main circuits, a fuse being placed on both the positive and negative wires The whole of the scheme for the electric lighting of this building has been devised by and carried out under the supervision of Mr. W. Howard-Smith, A.M.I.C.E, city engineer and surveyor. In addition to the installation at the public library buildings, there are three private installations in this city. One is at the works of Messrs. Carr and Co., biscuit manufacturers, and comprises one of Messrs. J. H. Holmes and Co.'s "Castle" dynamos, driven by a H. P. Tangye's steam-engine, and capable of supplying some 300 16-c.p. lamps or their equivalent. The second is at the cotton factory of Messrs. Ferguson Bros., and consists of a steam-engine and dynamo, by Messrs. Clarke, Chapman, and Co., capable of maintaining about 500 c.p. lamps. The third installation is that of Messrs. G. F. Brown and Co., ironmongers, and consists of a 3-h.p. Stockport gas-engine and a "Fawcus-Cowan" dynamo. Some 50 16-c.p. lamps, four 50-c.p. lamps, and one arc lamp of 1,000 c.p. are installed on the premises.

PROVISIONAL PATENTS, 1893.

DECEMBER 18.

24209. **Improvements in elements for secondary and other electric batteries, and in the manufacture of same.** Herbert Frederick Hoveler, 3, Stockwell-avenue, London.

24344. **Improvements in dynamo-electric machines.** John Augustin Kingdon, 28, Southampton-buildings, Chancery-lane, London.

24353. **A new or improved preparation of active material for electric accumulators.** Claude Kennedy Mills, 23, Southampton-buildings, Chancery-lane, London. (Charles Joseph Barbier, France.)

DECEMBER 19.

24389. **Improvements in electrode plates for secondary batteries.** Arthur Lehmann, 70, Wellington-street, Glasgow.

Digitized by Google

24392. **Improvements in and connected with electric motors for vehicles.** Charles Frederick Winkler, 70, Market-street, Manchester. (Complete specification.)

24409. **Improvements in or relating to means for conveying electrical currents to the workings of coal and other mines.** Harold Bonser, 323, High Holborn, London.

24414. **An improved means of underground current supply for electric railways.** William Phillips Thompson, 6, Lord-street, Liverpool. (August Rast, Germany.)

24417. **Improvements in electric or galvanic batteries.** Joseph Baxeres Torres, 13, Golden-square, London.

24442. **A new or improved electrical accumulator plate.** Claude Kennedy Mills, 23, Southampton-buildings, Chancery-lane, London. (Charles Joseph Barbier, France.)

24446. **Improvements in electric lamps.** William Allen Phillips, 46, Lincoln's-inn-fields, London (Date applied for under Patents, etc., Act, 1883, sec. 103, June 3, 1893, being date of application in United States.)

DECEMBER 20.

24471. **Improvements in electric supply meters.** William Thomson, Baron Kelvin, 154, St. Vincent-street, Glasgow.

24472. **Apparatus for evaporation, distillation, or concentration of liquids by means of heat produced by an electric current.** James Thomson Bottomley, 154, St. Vincent-street, Glasgow.

24517 **An improved advertising reflector for the top of electric light globes.** Frederick James Mockler, 97, Newgate-street, London.

24557. **Improvements in or relating to electric printing or signalling apparatus.** Andrew Ainslie Common, 45, Southampton-buildings, Chancery-lane, London.

DECEMBER 21.

24606. **Improvements in the means of suspending arc and other electric lamps and fittings.** Ernest Alexander Claremont, 53, Arcade-chambers, St. Mary's-gate, Manchester.

24607. **An improved insulated lever for use in electrical switches and other like appliances.** Ernest Alexander Claremont, 53, Arcade-chambers, St. Mary's-gate, Manchester. (Complete specification.)

24608. **Improvements in the construction of and in the means for fixing flywheels to the pulleys of dynamo-electric motors and generators.** Ernest Alexander Claremont, 53, Arcade-chambers, St. Mary's-gate, Manchester. (Complete specification.)

DECEMBER 22.

24730. **Means for use in combination with conduits or conductors for the supply of gas or other fluid or of electricity for indicating the time during which such gas or other fluid or electricity has been consumed.** Francis George Savage Curtis, 47, Lincoln's-inn-fields, London.

DECEMBER 23.

24736. **Improvements in electric bells.** John Whitaker and Thomas Percival Pollitt, 64, Barton-arcade, Manchester.

24751. **Improvements in safety appliances for use in connection with generating and distributing apparatus for high-pressure electrical currents** John Smith Raworth, 46, Lincoln's-inn-fields, London.

24757. **Certain improvements in electric apparatus for stopping steam or other engines.** William Arnold and William Crowther, Commercial-street, Halifax.

24771. **Improvements in electrical measuring instruments.** Frederik Vilhelm Andersen, 14, Westdown-road, Catford, Kent.

24790. **Improvements in brush-holders for dynamo-electric machines.** Rookes Evelyn Bell Crompton, 55, Chancery-lane, London.

DECEMBER 27.

24864. **Improved methods and means of compounding dynamo-electric machines.** Elihu Thomson, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

24865. **Improvements in insulators for electric wires.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (William Brisbane Rand, United States.) (Complete specification.)

24867. **Improvements in electric railways.** John Charles Love, and Albert Gallatin Wheeler, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

24871. **Improvements in dry batteries.** Harry Torrey Johnson, 323, High Holborn, London. (Complete specification.)

24889. **Improvements in connection with phonographs, graphophones, and similar sound recording and reproducing machines.** Jonathan Lewis Young, 4, Moorfields, Fore-street, London.

24911. **Improvements in electric cables and in the method of making the same.** Thomas Jefferson Dewees, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

DECEMBER 28.

24926. **Improvements in the method of and means employed for completing electric circuits.** Walter Brierley, Penny Bank-chambers, Halifax. (Philipp Weber and Johann Heinrich, Germany.) (Complete specification.)

24946. **Improvements in coverings for electric wires.** Franklin Streeter Randall, Edward Packard, John Robinson, and William Julian Chaninel, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

24948. **A time electric switch.** Edward Carstensen de Segundo and Walter Derham, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

24951. **Improvements in electrical measuring instruments.** Francis Henry Nalder, Herbert Nalder, Charles William Scott Crawley, and Alfred Soames, 16, Red Lion-street, Clerkenwell, London.

DECEMBER 29.

24979. **Improvements in instruments for measuring and recording electric pressures and currents.** William Thomson, Baron Kelvin, 154, St. Vincent-street, Glasgow.

25009. **Electric heater and its application to electric cigar-lighters.** Friedrich Wilhelm Schinder, 433, Strand, London.

25013. **Improvements in or connected with apparatus for feeding carbons in electric arc lamps.** Frederick Hallows and Frederick John Beaumont, 166, Fleet-street, London.

25016. **An improved rosette for electric wires.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (William Brisbane Rand, United States.) (Complete specification.)

DECEMBER 30.

25056. **Improvements in incandescent electric lamps.** Francis Lyst, 64, Somerville-road, Hatcham, London.

25082. **Improved means for arranging and intensifying the magnetic fields of dynamo-electric machinery.** James William Thomas Cadett, 33, Southampton-buildings, Chancery-lane, London.

NOTES.

Newport.—The County Council have decided to purchase the tramways of the local company.

The Charing Cross-Hampstead Railway.—There will be no opposition on Standing Order proofs to the Bill of this company.

Edinburgh.—The Town Council decided on Tuesday to light the portion of the High-street from the Tron Church to Jeffrey-street by electricity.

Lecture.—A short lecture on "The Discharge of Electricity through Rarefied Gases," was delivered a few days ago by Dr. Riley, D.Sc., at the annual conversazione of the Bradford Technical College.

Stirling.—The Town Council have resolved to refuse their consent to the application of the Caledonian Electric Supply Company for a provisional order to supply the burgh with electric light. The company will, however, proceed with their application.

Towing by Electricity.—A company has been formed in Maryland, U.S., for the purpose of applying electricity on the Chesapeake and Ohio Canal. It is intended to make further experiments on the Erie Canal with boats of which the usual bluff bow and stern will be modified.

Students of the Institution.—A students' meeting of the Institution of Electrical Engineers will be held on Friday next, the 19th inst., at 28, Victoria-street, Westminster. A paper will be read on "Multiphase Currents and their Applications," by Mr. C. V. Drysdale, student.

Telephony Between Belgium and Germany.—Negotiations are proceeding between the German and Belgian authorities with a view to the establishment of a telephone line between Cologne and Aix-la-Chapelle on the German side, and between Verviers and Brussels on the Belgian side.

Royal Institution.—On Tuesday next, January 16, Prof. Charles Stewart will begin a course of nine lectures on "Locomotion and Fixation in Plants and Animals." The Friday evening meetings will begin on January 19, when Prof. Dewar will deliver a discourse on "Scientific Uses of Liquid Air."

Engineers and Shipbuilders.—The fourth general meeting of the present session of the North-East Coast Institution of Engineers and Shipbuilders will take place at the Durham College of Science, Newcastle, on Tuesday next. A paper will be read by Mr. J. R. Fothergill "On Mercantile Marine Engineers."

The Government and Telephony.—It appears there is now no prospect of the agreement between the Government and the National Telephone Company being laid on the table during the present session. Members interested in the subject intend to call urgent attention to the matter at the earliest possible moment next Session.

Morecambe.—The Local Board on Tuesday endorsed a resolution of the Finance Committee protesting against the raising of the price of gas by the gas company from 3s. 11d. to 4s. 2d. per 1,000 cubic feet. It was suggested that the electric light should be adopted, but eventually it was decided to await a reply from the company.

The "Medical Battery" Company, Limited.—The case for the prosecution closed on Wednesday in regard to the charges of conspiracy to defraud brought against Messrs. C. B. Harness, J. M. M'Cully, and C. B. Hollier, in connection with the "Medical Battery" Company. The case for the defence was adjourned.

Utilising Tidal Power.—Another scheme has been advanced for utilising the rise and fall of the tides as motive power. Experiments are reported to have been made with the invention on the coast of Cheshire, where a tidal mill of about 4 h.p. has been used to supply power for driving a dynamo for lighting a house by electricity.

A Charge Dismissed.—A verdict of "Not guilty" was returned on Wednesday at the Quarter Sessions for the city of Leeds in the case brought against Mr. C. H. Bent, late manager of the Roundhay Park Electric Tramway for the Thomson-Houston Company, who was charged in the indictment with falsifying the books of the company with intent to defraud.

Institution of Civil Engineers.—The roll of the Institution of Civil Engineers has lately been increased by the election of five honorary members—the Duke of Devonshire, Dr. Frankland, Sir Douglas Galton, Prof. von Helmholtz, and the Marquis of Salisbury. The number of that class has thus been raised to 20. The gross total of the several classes composing the institution has now reached 6,520.

Royal Meteorological Society.—The annual general meeting of the society will be held at 25, Great George-street, Westminster, on Wednesday at 8.15 p.m., when the report of the council will be read, the election of officers and council for the ensuing year will take place, and the president (Dr. C. Theodore Williams) will deliver an address on "The Climate of Southern California," which will be illustrated by a number of lantern slides. This meeting will be preceded by an ordinary meeting, commencing at 8 p.m.

Lighting at Leeds.—The Yorkshire House-to-House Electricity Company, which commenced to supply the electric light in Leeds last year in certain districts, began business in May with engines of 500 h.p., and engines of 200 h.p. were added some time ago. The directors are now preparing to lay down two additional engines, each of 400 h.p., with the object of both extending the district to be supplied with the electric light and to add further premises on the routes already supplied. They hope in a few months to be able to reduce the cost of the supply.

Personal.—In our issue of December 29th we omitted to state that Mr. Reginald J. Wallis-Jones resigned his appointment with Messrs. Woodhouse and Rawson United, Limited, to join Messrs. Kincaid, Waller, and Manville, the well-known consulting civil and electrical engineers. Mr. James Paxman, who has for many years been the sole proprietor of Messrs. Davey, Paxman, and Co., engineers, Standard Ironworks, Colchester, has taken into partnership his son, Mr. William Paxman, from January 1. The title of the firm remains unchanged.

Electric Traction at Hartlepool.—A joint deputation of the Corporations of the two Hartlepools have visited Leeds at the invitation of Messrs. Sellins and Ashby, the promoters of the project to work the Hartlepool tramways by electric power, to inspect the working of the system there in use. The Mayors of Hartlepool and West Hartlepool headed the respective deputations, which included the borough engineers of both towns. They appeared to be satisfied, by what they saw, with the advantage of the system, upon which they will report to the respective committees.

Society of Arts.—On Wednesday next, at 8 p.m., a paper will be read on "White Lead Substitutes," by Mr. A. Laurie, M.A. On Thursday, at 8.30 p m., a paper will be presented on "The Petroleum Fields of India: thei

Digitized by Google

Present Condition and their Probable Future," by Mr. R. D. Oldham, A.R.S.M., Superintendent Geological Survey of India. This meeting will be held at the Imperial Institute, S.W. On February 8, Mr. E. O. Walker, C.I.E., formerly of the Indian Telegraph Department, will read a paper on "Telegraphic Communication between England and India: Its Present Condition and Future Developments."

Telegraphy in Africa.—"It had been hoped in the first months of the year," remarks the *Times*, "that the peaceful strengthening of the links of communication with the north by means of telegraphs and railways would have sufficed to bring about the gradual inclusion of the Matabele nation in the web of mining and agricultural progress. The great scheme for a trans-continental telegraph, which took shape under the initiative of Mr. Rhodes in the early summer, has been so far practically advanced that the line has been surveyed, and material for the construction of the whole section between Salisbury and Zomba, in Nyasaland, has been sent out."

More Gas Explosions.—Two explosions occurred simultaneously on Monday morning, when two manhole covers, one situate at the corner of Creed-lane and Ludgate-hill, and the other in St. Paul's-churchyard, were blown into the air. On Tuesday, at a meeting of the City Commissioners of Sewers, Mr. Ross (in the absence of the engineer) said, in reply to a question, that he had written to Mr. W. H. Preece, and asked for a report on the subject. He had also addressed a communication to the City of London Electric Lighting Company, who had replied stating that the explosion was due to an accumulation of gas in the manholes in question.

A Powerful Lighthouse Light.—The lighthouse on Fire Island, at the entrance to New York Harbour, is about to be provided with plant which will, it is submitted, produce an electric light of 240,000,000 c.p. This tremendous light will be visible from a distance of 24 miles, and in foggy weather from 10 miles, and it is claimed that its reflection on the sky will be seen at a distance of 100 miles. The present light shows for five seconds every minute, but the new light will be visible for five seconds, with dark interval of one second. The present light is visible 16 miles in clear weather. The gigantic lens, 9ft. in diameter, which was exhibited in the French section of the World's Fair at Chicago, has been purchased by the United States Government, and will be used for the new light.

The South Staffordshire Electric Cars.—The paragraph which appeared in various papers stating that a prize of £10,000 is offered to electrical engineers for the introduction of an underground electric system improperly described the overhead system at work on the South Staffordshire Tramway lines. The overhead electric system has been at work on these lines from January 1, 1893, since which time it has run through the principal and crowded streets of Walsall, Wednesbury, and Darlaston, and has given satisfaction to the public, the local authorities, and the company. It is the only system of its kind in existence, the overhead line is on one side of the street only, there are no cross or pull-over wires, and the objectionable features of the American systems are avoided.

He Lost His Character. — The electric light is reported to have caused a man to lose his character. It appears that a clerk to a local board, who is also a solicitor in large practice, got the electric light laid on at his office in a small town in North Wales. Coal, however, fell short, and the light became intermittent. When the clerks were working late on Saturday night they left the switches on, in the hope that the light would presently appear, but they forgot to switch off. The consequence was that when the good people of the town were proceeding to their places of worship on the evening of the Sabbath they found the lawyer's office alight, and, of course, jumped to the conclusion that both he and his clerk were drawing up bills of costs when they ought be contributing to the collections.

Suggested Amendment of the Patent Laws.—The Society of Chemical Industry recently appointed a committee to enquire into the patent laws, with a view to their amendment. This committee has now decided to present a memorial to the Government praying for the appointment of a Royal Commission to enquire into the subject; and the Institution of Civil Engineers, the Society of Arts, the Chartered Institute of Patent Agents, Chambers of Commerce, and other public bodies, are to be asked to join in the memorial. At a meeting of the London section of the society, held at Burlington House, the matter was under discussion, and, among others, resolutions were passed advocating a longer period of protection for inventions than the present 14 years; a preliminary examination of specifications by the Patent Office; the limitation of the power of disclaimer to three years from the date of the patent; the reduction of fees, and the trial of all patent actions by a rota of specially selected judges of the High Court.

Electric Traction at Douglas. — The Douglas Town Commissioners had before them on Wednesday an application on behalf of the Douglas and Laxey Coast Electric Tramway Company, Limited, for a further concession, as from December 6, 1897, of 21 years for the working of the Douglas Bay Tramway. Under ordinary circumstances the tramway undertaking would lapse into the hands of the Commissioners at the first-mentioned date. In consideration of the further concession being granted, the applicants agreed to pay the Commissioners 5 per cent. upon the gross receipts of the tramway from the present time up to December, 1897, and 12 per cent. on the gross receipts from December, 1897, to December, 1918. Many members were of opinion that the town would do well to grant the application; but it was decided to hold the matter over for a fortnight. Several of the applicants attended the meeting and urged the Commissioners strongly to give them a decisive answer at once, as they could not guarantee that the offer would remain open for another fortnight.

An All-British Pacific Cable Needed. — The Dominion Minister of Trade and Commerce states that, although the date of the Canadian-Australasian Conference has not yet been fixed, it will probably be held at Ottawa before the summer. The *Canadian Gazette* remarks that: "Mr. Sandford Fleming had to pay £2. 11s. for a cablegram of two words from Sydney to his family at Ottawa, including a registration fee of 10s. 6d. to ensure delivery of the reply message at his hotel. Can one wonder that with such exorbitant charges the demand for an alternative and all-British Pacific cable is spreading so rapidly among Australian Governments and Australian commercial men? While in Australia, Mr. Fleming made a point of enquiring in the public libraries for a Canadian newspaper. Not a vestige of one, old or new, could he find. What cohesion and stability can an empire have when its leading members are thus isolated from one another? Canada and New South Wales are doing their utmost to put an end to this isolation by encouraging the mail steamship line between Vancouver and Sydney. The Canadian and Australian Colonies are anxious to follow up this effort by an all-British cable. Will the Imperial Government much longer persist in standing aloof and letting her colonies do alone the work of empire?"

Electric Motors on Battleships.—The system of heavy gun mountings and loading gear by Sir Joseph

Digitized by Google

Whitworth and Co. was tried the other day on board her Majesty's ship "Centurion," at Portsmouth. The supply of ammunition is arranged in such a way that the guns can be loaded at any angle of training, without coming to a fixed loading station after each discharge. It is intended to fit electromotors to the elevating apparatus, designed for a large angle of fire—viz., minus 7deg., plus 35deg. elevation. The loading station being almost horizontal, the electromotors will be valuable adjuncts to the hand elevating appliances when the guns have to be moved through the angle from loading position to maximum elevation or thereabouts. The motors, however, are merely auxiliaries, as the elevation can be accomplished by the manual gear, though less expeditiously. An electric motor is being fitted to a hoist for rapid transport of the charges to the guns. The sighting arrangements are similar to those in many others of her Majesty's ships, except that, owing to the large angle through which the guns move, special arrangements have had to be adopted to ensure the angular movement of the sight-bars through the extreme range. Each shield has two sighting-hoods, from which either of the guns in the redoubt is trained and elevated, the latter operation being effected by means of an electric switch or by a hand-wheel.

How to Prevent Gas Explosions in Manholes. In connection with the recent explosions of gas in manholes at Glasgow, Manchester, and on Monday in Ludgate-hill, a correspondent to a provincial paper makes the following suggestion: "Prevention is the best cure, and the sooner gas explosions connected with the electric light mains can be prevented the better. On Saturday I noticed that another gas explosion had occurred, but I also noticed, though it may not have been understood by the public, that the cause of the explosion was in no way electrical. Gas had certainly accumulated in the electric light conduit from some leaking gas-pipe in its vicinity, but the cause of the explosion was the approach of a lighted taper for the purpose of examining the mains. Some will say that there should have been no light, or there should have been no spark; and others will say that there should have been no leaking gas, but there are times when these things evidently cannot be prevented. Gas will leak, but we may do something to prevent its accumulation in our electrical conduits. I therefore propose that at every manhole, and at intervals between, escape-pipes be laid down so as to carry any accumulating gas away. These pipes would be laid underneath the pavement slabs, and then up the fronts of buildings, terminating at the top in a suitable cover to prevent rain coming in, but admitting of the escape of gas. At the bottom of this long pipe may be placed a trap to collect and carry away any water that may be deposited by the gas itself."

Rewards for Discoveries and Inventions.—The Committee on Science and the Arts of the Franklin Institute of the State of Pennsylvania desire us to draw attention to the fact that the institute may grant, or recommend the grant of, certain medals for meritorious discoveries and inventions which contribute to the promotion of the arts and manufactures. The character and conditions of these awards are briefly stated in the following: The Elliott Cresson medal, founded in 1848 by the gift of the late Elliott Cresson. This medal is of gold, and by the terms of the deed of trust may be granted for some discovery in the arts and sciences, or for the invention or improvement of some useful machine, or for some new process, or combination of materials in manufactures, or for ingenuity, skill, or perfection in workmanship. The John Scott legacy premium and medal (20dol. and a medal of bronze), awarded by the city of Philadelphia. This is devoted to rewarding ingenious men and women who make useful inventions. The Edward Longstreth medal of merit is of silver, and may be awarded for useful invention, important discovery, and meritorious work in, or contributions to, science or the industrial arts. Further information as to the manner and form in which applications for the investigation of inventions and discoveries should be made will be sent to interested parties on application to Mr. William H. Wahl, secretary of the Franklin Institute, Philadelphia, Pa., U.S.A.

A Peculiar Occurrence at Bournemouth.—A strange occurrence is reported as having happened in this town on Monday. It is stated that as a two-horse 'bus was proceeding along Meydrick-road one of the animals fell down dead, and the other commenced to quiver violently. The driver jumped off, and help arriving, those present soon felt the existence of an electric current. Two dogs passing by suddenly rolled over and yelled furiously, but got away. The presence of electricity is said to have been felt for some distance in the road, and it is supposed that a leakage occurred from the electric light mains underneath the road, and that the horse was probably killed by an electric shock. With regard to this, the Board of Trade, at the request of the Bournemouth Town Council, sent down Major Cardew on Tuesday to enquire into the cause of this accident. The *Standard* states that Major Cardew visited the scene of the occurrence, and had two iron chambers opened near the spot through which the wires pass. Several people stated that on assisting to get the horses up they felt slight shocks like pins and needles pricking them, and a cabman named King told the inspector that he had to leave off helping to unharness the horse, and rub his legs on account of the peculiar sensation which he felt. Others spoke as to seeing dogs jump about and bark and yell on passing near where the horse fell dead. The phenomena ceased when the electric light company cut off the current. Major Cardew had a test battery applied to the wires, but it appeared to reveal no leakage, and at present there appears to be no satisfactory solution of the occurrence.

Boiler Incrustations and Deposits.—Before the Junior Engineering Society, on Friday last, a lecture on this subject was delivered by Prof. Vivian B. Lewes, F.I.C. The lecturer having pointed out the serious injury occasioned to boilers and the waste of fuel due to the formation of incrustations, traced the history of various sources of water supply, and showed how the water acquired the power of forming deposits in steam generators. These deposits consist mainly of calcic carbonate, calcic sulphate, magnesic hydrate, and silica, the chemical processes which lead to their deposition in the feed-water differing in each case. Calcic carbonate, which constitutes the principal ingredient in fresh-water deposits, is thrown down in a dense form by the breaking up of soluble calcic bicarbonate under the influence of heat, and if it is nearly pure it forms a mud in the boiler, which can to a great extent be got rid of by blowing off. Calcic sulphate, however, is deposited by an entirely different action, as its solubility decreases with rise of temperature, high pressure, or great increase in the saline properties of the solution; and its wonderful power of hardening deposits and binding them together into an incrustation, which can only be removed by the use of hammer and chisel, makes it a most dangerous constituent of such deposits. This hardening power is due to the fact that it deposits from water in the form of small angular crystals, and in this form gets mixed with the calcic carbonate mud. As these crystals become heated they lose water of crystallisation, and change their form into fine needle-shaped crystals, which bind the mass

Digitized by Google

together. Examples were given of scales from various waters, and it was shown that fresh-water incrustations may be looked upon as consisting chiefly of impure calcic carbonate, whilst the deposit formed by the use of sea-water is principally calcic sulphate. Brackish waters give incrustations consisting of nearly equal portions of these substances. The question of oily deposits on plates was next considered, and the lecturer pointed out that according to recent researches mere wiping of a boiler plate with a greasy rag causes a serious diminution in its power of transmitting heat, whilst with an oily deposit $\frac{1}{16}$in. in thickness, plates in some cases became so overheated as to be unable to withstand the pressure upon them, and collapse of the furnace crowns sometimes ensued. The question of anti-incrustators was then dealt with, and the lecturer expressed his opinion that if manufacturers were obliged to use a hard water, the most reasonable method they could adopt was to soften it on a large scale before putting it into the boiler, as otherwise serious complications would arise in the boiler itself.

The Electro-Harmonic Society.—The next smoking concert of this society will take place on Friday, the 26th inst., at the St. James's Hall Restaurant, Regent-street, W., commencing at eight o'clock. The following is the programme—Artistes: The Dilettante Vocal Quartette; Mr. James Brown; Mr. Edward Dalzell; Mr. Fred. Bevan; Mr. Robert Hilton; harpist, Mr. G. T. Miles; pianist, Mr. Alfred E. Izard; recitations, Mr. I. K. Boddy; humorous songs, Mr. J. Kift; musical directors, Messrs. T. E. Gatehouse and Alfred E. Izard (a Blüthner Aliquot concert grand piano will be used). Programme—Part 1: Part song, "The Hunt is Up" (Hatton), the Dilettante Vocal Quartette; air, "Sombre Woods" (Lully, 1684), Mr. Robert Hilton; harp solo, "Winter" (Thomas), Mr. G. T. Miles; quartette, "The Young Lover" (Koschat), the Dilettante Vocal Quartette; recitation, "The Siege of Lucknow" (Tennyson), Mr. I. K. Boddy; pianoforte solo, "Caprice in E" (Paganini-Schumann), Mr. Alfred E. Izard; new song, "Thy Heart's Rest" (Bevan), Mr. Frederick Bevan; humorous song, Mr. James Kift. Part II.: Glee, "L'ape e la Serpe" (Spofforth), the Dilettante Vocal Quartette; air, "Where e'er You Walk" (Handel), Mr. E. Dalzell; harp solo, "Love's Fascination" (Welsh air), Mr. G. T. Miles; catch, "Would You Know my Celia's Charms" (S. Webbe), the Dilettante Vocal Quartette; recitation, "The Charity Dinner" (Moseley), Mr. I. K. Boddy; song, "I'm a Roamer" (Mendelssohn), Mr. Robert Hilton; part song, "Good Night Beloved" (Hatton), the Dilettante Vocal Quartette; humorous song, Mr. James Kift.

The Use of Wind Power.—In the course of an article on this subject, the *Pall Mall Gazette* says: "Recent discovery has plainly shown that rapidly-oscillating currents send out waves exactly similar to light-waves, but having a much greater wave length. Attempts have been made to get alternate-current machinery of such frequency as to send out such waves. If these are practically successful, light will be generated with much less expenditure of energy, and windmills of very moderate power will be quite sufficient to produce the necessary electric currents. And windmills have been used for the purpose in several places. Prof. James Blyth has been successful in removing many of the difficulties in the way of utilising the wind. He was the first to make trial of the windmill at Marykirk, in Scotland. He first adopted the English type of windmill having four arms and canvas sails. But the sails were too easily torn during a head wind—the very time they were most required. Next he used the American type, having a number of arms and blades of cast iron. But his best form very nearly satisfies all requisites—namely, to be always ready to go, to go without attendance, and to go through the wildest gale. To four strong arms, each about 26ft. long, he attached semi-cylindrical boxes, the opening of each box being 10ft. by 6ft. The vertical shaft is a long rod of iron 5in. in diameter. At the lower end it carries a massive pit wheel which actuates a train of gearing, and drives a flywheel 6ft. in diameter. With a fair wind speed it gives 4 e.h.p., and it works very satisfactorily in a strong gale. Even in that form windmills can be used for lighting lighthouses, which are always on exposed situations, where wind is plentiful, and often in such out-of-the-way places that stores of coal for generating the electric light in any other way could only be sent with difficulty. The large windmill at the two lighthouses on Cap de la Heve, near Havre, has been working satisfactorily. They may also be used for the lighting of private country mansions and factories, especially when these are in sufficiently exposed situations. But if the method suggested by Prof. Blyth be ultimately successful to provide the light by rapidly-oscillating currents, windmills of very moderate power will be sufficient. And the time may not be so very far distant when each house will have its own little windmill storing currents, which may be used to drive the alternate-current machines required in the production of light. Thus from a comparatively cold source light may be produced suitable for each house; and wind, as well as water, can be employed to give the light which is draining away so much of the coal supplies." The last two sentences, to say the least, express too sanguine a view of the subject.

English-Made Carbons for Electric Lighting.—It is a matter for regret that all the carbons used in England for arc lighting have hitherto been imported from abroad. The best quality, which must be used to attain the best results in this system of lighting, come from the Continent, while the inferior quality, used with much less satisfactory results, are an American product. The recent success of the arc light as a high-class illuminant has only been attained by the use of the superior continental carbons—a cored positive and a solid negative being used with a continuous current, both rods being cored with the alternating current. Unfortunately, solid positive carbons, often of poor quality, are still used to a large extent, and it is in these cases that the unsatisfactory burning of the lamps leads many to think still that the arc light is necessarily at times a dark light and always an unsteady light. Under the title of the English Electric Carbon Company, Limited, as mentioned in our last issue, a company has been formed to enter commercially into the manufacture of electric light carbons. The chairman of the company is Mr. John H. Darby, the managing director of the Brymbo Steel Company, Limited; and amongst the directors are Sir H. B. Robertson and Mr. J. C. Edwards, of Ruabon. The secretary and manager is Mr. T. Graham Littleboy, an electrical engineer whose connection with electric lighting will enable him to appreciate the necessities of carbon consumers. The factory has been erected at Brymbo, in North Wales, on the most modern lines, equipped with special machinery and appliances, and is now in full operation. The company have secured the rights to all the trade secrets and methods of manufacture of one of the best carbon-makers on the Continent. A laboratory and testing-room are provided, and the utmost care is used in the selection and treatment of materials and the testing of the carbons. By this means the good quality of the carbons produced will be regularly maintained. At present, only the very best quality carbons are manufac-

Digitized by Google

tured, and an exhaustive series of tests of those carbons in comparison with the best continental brands by experts who are very well known, show the company, we are informed, that they have good reason to be satisfied with the quality of their carbons, which in one set of tests were reported as burning "the best." As a consequence, they are sanguine of securing the orders for carbons which have hitherto gone abroad. The registered trade-mark of the company is "Phœbus," and under this name the carbons are being placed on the market. The company have forwarded us a copy of their price-list of carbons ranging in diameter from 8mm. ($\frac{5}{16}$in.) to 20mm. ($\frac{25}{32}$in.). Other sizes are, of course, made. There is no doubt that electrical engineers and consumers of carbons will give this endeavour to start this industry in England on a practical scale every encouragement and assistance.

Electric Haulage in Mines.—A system of electric haulage has been introduced in the mines of the Brock Coal Company, Scranton, Pa. The seam of coal worked averages about 31in. thick, but in some places it is as much as 42in. thick. The present production of the four drifts ranges from 300 to 400 tons per day. The inclination of the seam is very slight, being merely enough to ensure natural drainage for about 5in. in 100ft. The seam has a hard sandstone top and a soft fireclay bottom. It was desirable to have a substantial, economical, and convenient system of haulage suitable for a track laid with light rails running in headings or gangways where mule haulage was impossible, unless excessively large quantities of the fireclay bottom were taken up. Electric haulage was deemed the best for the existing conditions, and the contract for the two locomotives and the entire plant was given the General Electric Company. The success of the electric haulage in meeting and overcoming the difficulties was such as to win for the system the highest endorsement from the officials of the Brock Coal Company. Two locomotives are used, each of the same type and capacity. These locomotives are known as T. M. M., with a capacity of 1,500lb. draw-bar pull each. They are each of the following dimensions: 32in. high, 48in. wide and 9ft. 6in. long. The wheels are 30in. and the axles $3\frac{3}{8}$in. in diameter. The wheel base, which is rigid, is 42in. Each locomotive weighs about $4\frac{1}{4}$ tons, and has two motors of the new iron-clad street-railway type equipped with four-pole Gramme toothed ring armatures. The armatures are series connected so as to use only two brushes each, and these are on the upper side of the commutator and in an easily accessible position. The armatures are connected with the axles by machine-cut single-reduction gears running in gear cases filled with oil. The frames are of cast steel and of such shape as to thoroughly protect the spools and armatures, which are thoroughly waterproofed. The trolley arms are supplied with universal joints, so that they accommodate themselves to any position required by the location of the trolley wire. The feeder is insulated copper wire of No. 00 B. & S. gauge, and the trolley wire is a bare copper wire of No. 0 B. & S. gauge. The feeder wire runs from the power-house across the tracks to a point on the hillside above the tracks, and thence to No. 5 drift. The trolley wire runs along the upper side and close to the track. The power is supplied to the locomotives from a Thomson-Houston D 40-220 volt generator run by an old-style McEwen engine of about 80 h.p. Dynamometer tests made on one of the locomotives showed a steady draw-bar pull of 2,700lb., or nearly 100 per cent. overload. The locomotive is very compact, and is low enough to run in much smaller headings than those at the Brock mine. It is conveniently arranged, so that the motorman can control it perfectly without leaving his seat. On the surface the trolley wire is suspended at a uniform height and distance from the rail. This is also the case in the mine, as far as possible, but it is not always practicable, and a special trolley arm is therefore required.

Science in 1893.—The *Times* of Wednesday contains a long review of science in 1893. We abstract the following concerning chemistry and physics: Some of the most interesting work of the year has been done at the Royal Institution, where, with the aid of new and powerful machinery, Prof. Dewar has produced liquid air in the large quantities required for purposes of research. Thus armed with the means of studying the behaviour of bodies at very low temperatures, he has carried out, in conjunction with Prof. Fleming, an extensive and laborious series of investigations upon the electrical conductivity and resistance of metals at various temperatures down to 200deg. below zero. The results point to the total disappearance of resistance in pure metals at the zero of absolute temperature. In the domain of applied science one of the most noticeable features of the year is the steady extension of the employment of electricity for effecting direct decompositions, hitherto brought about by more circuitous methods. The production of sodium and aluminium, for example, has been immensely cheapened, and the electrolysis of brine threatens to become a formidable rival to the older modes of obtaining alkali and bleaching powder. But the obvious advantages of electrolytic processes will not suffice to ensure their adoption on a really extensive scale so long as electricity has to be obtained through the steam-engine. What is indispensable is a more direct utilisation of natural forces, and it is to this object that inventive talent may now be most hopefully applied. We may not improbably witness in the near future a considerable displacement of industries in order to secure reasonable proximity to water power. Lord Armstrong many years ago led the way in the production of electric light by means of previously unconsidered water power, and his example has since found many imitators. From this point it is easy to advance to the production of electricity upon a great scale for industrial purposes, and countries possessing available resources of the kind required may compete on favourable terms with the possessors of an abundant coal supply. The artificial production of diamonds has been frequently attempted, and success has more than once been claimed. It has, however, been reserved for M. Moissan to solve the problem by crystallising carbon under enormous pressure from solution in cast iron. Carborundum, a substance of hardness scarcely, if at all, inferior to that of the diamond itself, has been before the world for some time, and was used two years ago by M. Tesla to cover the terminals in some of his experiments with high-frequency currents. Its composition and mode of manufacture are now made known. It is a carbide of silicon, produced by subjecting a mixture of carbon and silica to the intense heat of an electric furnace. It has been successfully used to polish diamonds, and will undoubtedly find extensive employment in the arts. Ordinary emery or corundum, in the form of the emery-wheel, is now among the most efficient of labour-saving agencies in our workshops, but is far surpassed in hardness by the new material. In metallurgy, among the more important work, may be mentioned the continued researches of M. Moissan, who, aided by the electrical furnace, has reduced to the metallic state certain refractory oxides, such as those of chromium, uranium, and calcium, obtaining both the pure metals and carbides of the metals. Prof. Roberts-Austen's lengthy investigations on the effects of impurities on masses of metal have yielded results of scientific interest, and have also enabled him to settle several disputed questions of much industrial importance, especially to engineers.

CRANES AND CRABS.

(Concluded from page 11.)

A very similar type of crane to that last mentioned has been designed by Messrs. W. Sellers and Co., the well-known Philadelphia machine-tool makers and engineers, for the Niagara Falls power-house; but of course the size and capacity are much greater. The span of Messrs. Sellers's crane is 60ft.; maximum load, 50 tons; maximum hoist, 164ft.; speed of lift, from 5ft. to 10ft. per minute (proportionally smaller loads being raised at speeds of 20ft. and 40ft. per minute).

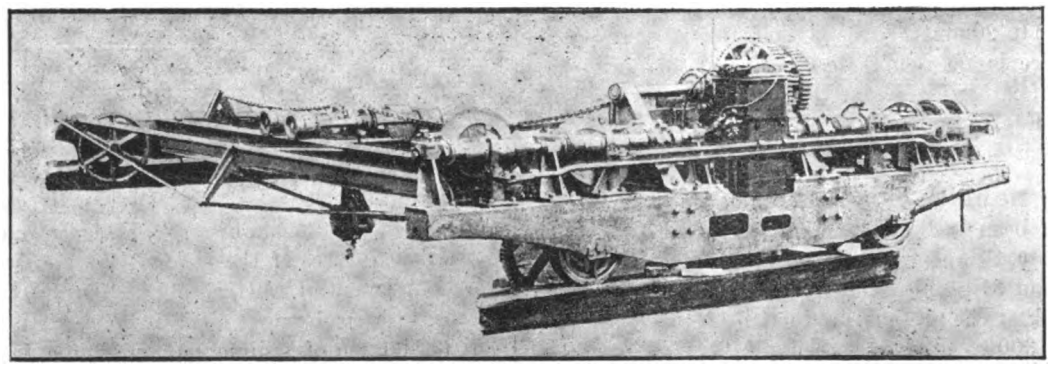

FIG. 1.—Two-ton Crane. Bushbury Works.

The cross traverse can be made either at 50ft. or 100ft. per minute, whilst the longitudinal traverse may also vary, being either 100ft. or 200ft. per minute.

All these motions are worked by means of friction clutches from a constant-speed electric motor having a capacity equal to about 45 h.p., and connected by a belt with a first motion shaft. A framework, or housing, fastened to the side of the crane girders, is made to carry three sets of friction clutches on parallel shafts, which operate spur wheels running loose upon the shaft. The latter, which gear together, receive their motion from the pulley through another clutch shaft connected with the pulley shaft by gears of two ratios, thus providing a fast or slow movement for the whole train. An idler, or an intermediate shaft, is employed to reverse the motion of one set of clutch gears. By this arrangement it will be seen that the clutch wheels on any shaft are run in opposite directions, and that by engaging one or the other of the clutches the shaft may be made to rotate in either direction desired; thus, without reversing the motor, which runs continuously in the same direction at the same speed, any motion of the crane can be effected in either direction and at a variety of speeds. These three operating clutch shafts are coupled respectively by suitable trains of gearing to the bridge travelling mechanism, the travelling crab, and to the hoisting chain.

In this case, as in most others where the same type of crane is employed, practically the whole of the gearing may be carried at one end. The hoisting is done through a long horizontal shaft and bevel gear, parallel with the crane bridge girders, whilst the crab traverse is usually effected by means of a chain or wire ropes wound and unwound upon a geared barrel or drum at one end of the crane.

There is a very complete and well-designed set of small single-motor cranes at the Bushbury works of the Electric Construction Company, and we append two illustrations which will serve to show these, perhaps, more clearly than by words alone. The Bushbury works are notable for other reasons also: as an instance, all the machine tools in the various shops are driven by electric motors without the intervention of any countershafting. Of course a supply of electric energy is available for all these motors from one large dynamo-machine driven by the works engine, and hence the matter of crane equipment becomes very easy and straightforward, no special generating plant being required.

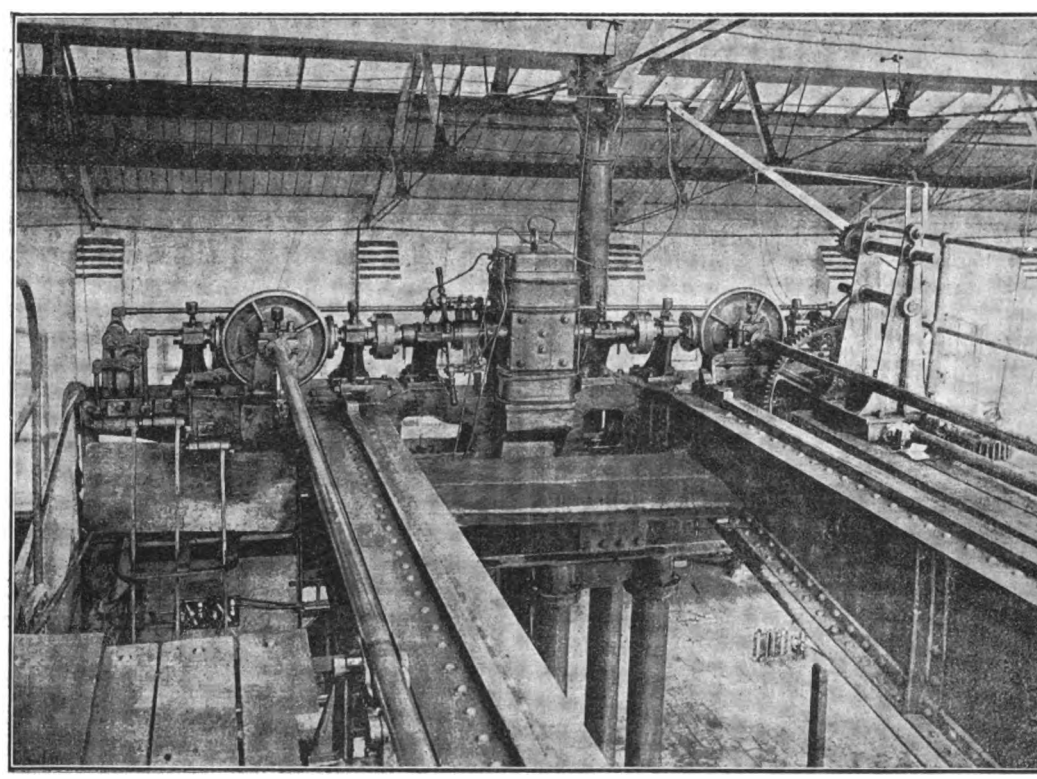

FIG. 2.—Ten-ton Crane. Bushbury Works.

Of the Bushbury cranes illustrated herewith, the small

Digitized by Google

one has a capacity of two tons, and is operated by a shunt-wound motor running in one direction only at 900 revolutions per minute. The motion of the armature spindle (which is extended almost the full depth of crane frame) is communicated by means of friction clutches to a geared shaft for the longitudinal travel, and to a somewhat similar arrangement for the cross traverse, which is done by winding up a chain in either direction upon a drum at the motor end of crane. The hoisting chain is carried from another drum or geared barrel, worked by the motor through friction clutches, to a pulley on the crab, passing thence to the crane hook, and back again upwards over another pulley on the crab, the end being finally secured in the usual way to a bracket on the far end of the crane frame.

The second illustration shows a 10-ton crane in the Bushbury works erecting shop; this is very similar in most respects to that already described, and the engraving brings out pretty clearly the arrangement of lengthened armature spindle with friction gear operating the different motions. It also shows the travelling contact by which the current required to work the motor is obtained. This consists of a bare wire attached by means of insulators to the tie-rods or other parts of the roof structure, and connection is maintained through a metal slipper or slide-piece flared out at the ends and pressing upwards against the underside of the wire. The slipper itself is carried at the end of a wooden pole attached to the crane frame, with a flexible wire connection to the motor.

The latter machine is also shunt wound as in the small cranes, and similarly runs at a speed of 900 revolutions.

Arrangement of a different kind to this becomes necessary when three motors are employed, instead of one only, to operate the several movements. The long shafting required to drive the hoist gear, and the chain or wire ropes for the cross traverse, are avoided altogether in such a case, a travelling contact alone being wanted to convey current to the crab and traverse motors.

The illustration, Fig. 3, shows a crane of the three-motor type, with a hoisting capacity of 30 tons. The three motors employed are respectively 3 h.p. for the cross traverse, 10 h.p. for hoisting, and 10 h.p. for the longitudinal travel. A large number of combinations in direction and speed are given, as each motor is provided with a separate controller. The pressure of current used is 220 volts, and travelling contact between crane and the source of supply is kept up with two trolley wires running one on either side of the crane on insulators, copper brushes attached to the ends of the framework lifting the wires as they pass along, just as do the grips of cable tramcars. The motors on the crab receive current through carbon brushes, which slide along copper strips placed on the inside of the frame. The total longitudinal travel of the crane is 165ft., and the span about 27ft. The extreme height of lift is 21ft. 6in. This crane was designed and manufactured by the Morgan Engineering Company, the electric motors being of Thomson-Houston make. One final item of interest regarding the crane is the "solenoid" brake, which holds the hoisting gear automatically as soon as the current is cut off from the motor.

The well-known Oerlikon Works, of Zurich, have, however, with their customary enterprise, travelled still further in the direction of three-motor crane design, and have gone so far as to introduce triphase motors for this work. Fig. 4 represents an overhead travelling crane of this type, erected at the Oerlikon factory, and used there for ordinary works purposes. As in the last example, the travelling contacts by which the necessary currents are supplied to the motors, take the form of grips picking up the conductor wires, which are supported by insulators. Better contact, it is thought, is thus secured, owing to the possibility of dust lying on the top of the wires, and causing sparks if attempts should be made to take off current by a top contact.

The triphase motors are stated to run very easily and without the least trouble: they have, of course, no brushes or commutators, the only wearing parts being the bearings, which are provided with automatic oil-cups.

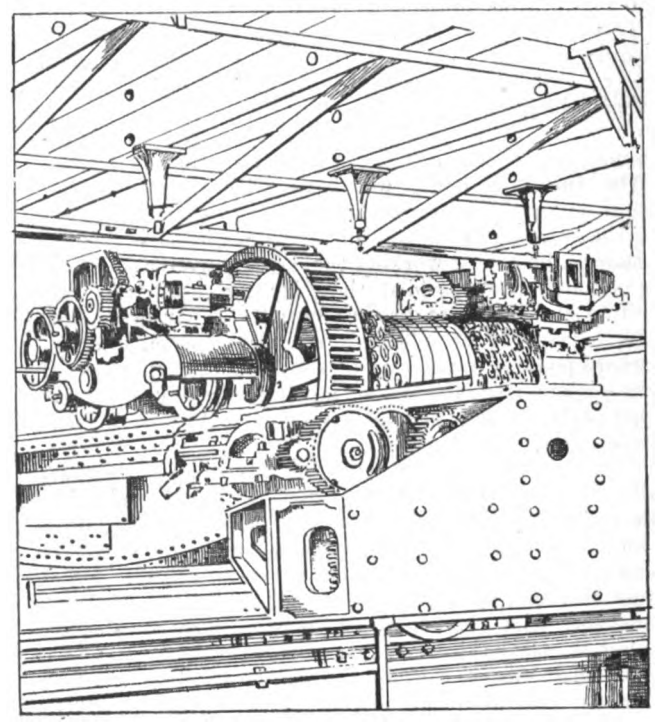

FIG. 3.—Thirty-ton Crane.

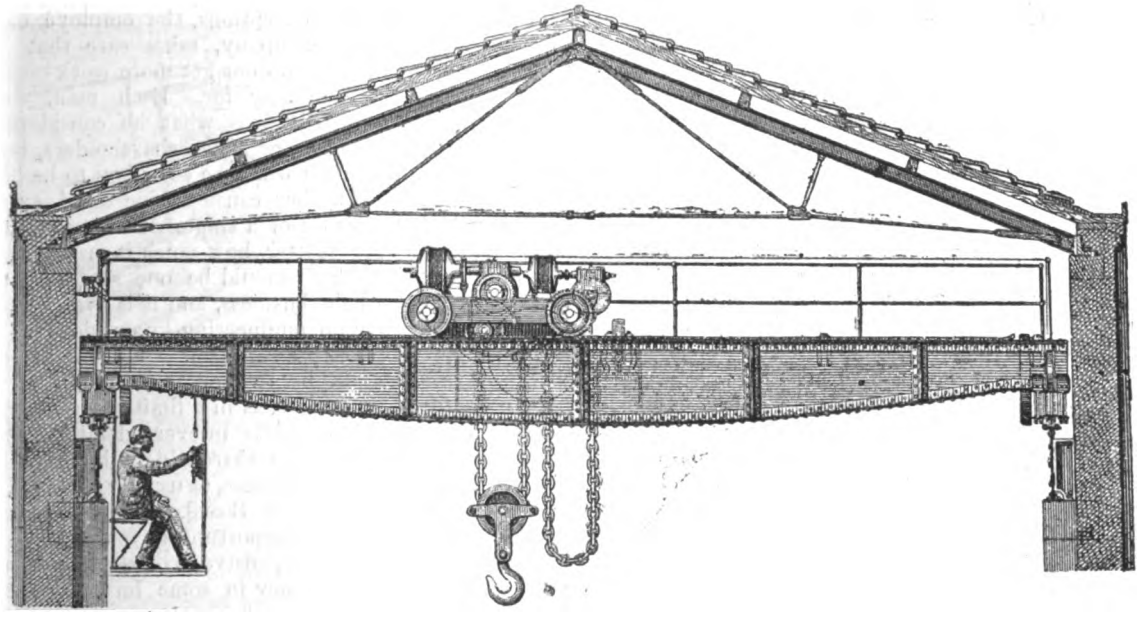

FIG. 4.—Crane with Triphase Motors.

Digitized by Google

Speed reduction is obtained by means of worm gear. The worm in each case is of high-quality steel, tempered and ground. The worm wheels are of phosphor bronze, with ball bearings; and the whole gear of each motor is boxed up so that it may run in oil. The other gears—on the crab, for instance—are of cast steel, with double helical teeth.

Fig. 4 is reproduced from the pages of *Le Genie Civil*, and Fig. 3 from *Cassier's Magazine*.

Instances of this type of crane are (as will have been already noticed from the references to the three-motor electric cranes at Crewe works) by no means uncommon; indeed, the question of one *versus* three-motor cranes can only be said at the present time to have just come up for discussion. It certainly is not yet by any means decided.

On the one hand, we have, with three motors, a better adaptation of each to the amount of energy required for the separate crane movements—that is, as in the last instance, the motor working the cross traverse need only be of small power, whilst those for the hoist and longitudinal travel are of greater output. They may, therefore, be worked at a higher electrical efficiency than is perhaps possible in the case of a single motor operating the whole crane, since the latter must necessarily be of sufficient power to effect at least any two, if not all three, of the crane movements.

Thus, in the 30-ton crane last described, it might be advisable to work the two traverses or travel and lift at the same time, and that would involve the use of at least a 15-h.p. or 20-h.p. motor. In any case, one of 10 h.p. would be required as a minimum for the heavy work, and for the cross traverse, where only a small amount of energy is consumed, such a motor might not work quite so efficiently at less than one-third load as at full output.

In small cranes, say, up to a capacity of 10 tons, it is, however, very doubtful whether any electrical economy is secured by the use of three motors instead of one. The powers required for the separate movements approximate more nearly to one another in proportion than they do with heavy cranes to lift, say, 30 or 50 tons. In consequence, the saving of a few per cents. in the motor efficiency is not of great weight in view of the extra complications of three motors instead of one; besides which a 6-h.p. or 8-h.p. motor may, if well and carefully designed, actually give as high an efficiency at quarter load as can be obtained from one of only 1½ h.p. to 2 h.p. at full load.

Of course the gearing incidental to speed reduction is the same in either case, but a slight disadvantage must certainly be debited to the single-motor crane by reason of the friction clutches, with the shafting and other gear required to operate the cross travel and hoisting, and which must undoubtedly cause some amount of mechanical power loss.

The whole question will be found to depend very largely upon cost of power—*i.e.*, working expenses *v.* initial outlay or first cost. A slight saving due to higher electrical efficiencies may be obtained from the use of three motors, at any rate, in large-powered cranes, but the capital outlay would be greater.

Perhaps at present the only conclusion to which we can reasonably point as being credible is that already alluded to—viz., that for small powers the single motor under ordinary conditions will serve every required purpose with most satisfaction. For heavy cranes it will be found best to employ distinct motors of suitable sizes, each worked at full load.

ELECTRICAL ENGINEERING AND LIMITED LIABILITY.

BY S. F. WALKER.

In the present article the writer proposes to discuss the question whether the adoption of the limited liability principle, the formation of limited liability companies, conduces to the advancement of the best interests of those who are engaged in the business or profession of electrical engineering. In the writer's opinion, the result of the adoption of the limited liability principle is very rarely of advantage to electrical engineers generally, and still more rarely to those who are connected with the particular concern which adopts limited liability, and should only be adopted where unavoidable.

In the first place, the expenses of all limited companies are greater than those of private firms doing the same work. They are obliged, necessarily, and for the protection of their shareholders, to work on certain lines in many of the details of their business that entail considerably more expense than would be necessary if the concern was not in the form of a limited company. In the second place, the capital account of a limited liability company is nearly always very largely in excess of that of a private firm doing the same work, while the actual working capital—the earning power—is often less than it should be notwithstanding the inflation. Promotion-money must be paid in some form or other; and usually it is paid partly in cash and partly in shares, the cash payment to the promoter reducing the working capital, while his shares swell the amount on which a dividend must be paid, if one is earned.

Company-promoting is unfortunately, though almost necessarily, a business in itself. Men engaged in the ordinary work of electrical engineering have rarely the time to hunt up men with capital, nor to do all that is implied in persuading them to take shares, and so this work is in the hands of a few men who have, or are supposed to have, a *clientèle* behind them ready to provide money for concerns their guide considers sound. But their guide's idea of soundness is too often formed solely on the view as to whether he and his friends can get anything out of the company, irrespective of the other shareholders. Can the company be made to run for a sufficient time to enable himself and his friends to unload at a profit, and to pocket something substantial in the way of remuneration for work they are supposed to have done? After this has been accomplished, it will perhaps be as well for the company to wind up, in order to make way for a fresh deal on the part of the promoter and his friends.

Another cause of the increased expense involved in carrying on business under the limited liability principle is the fact that the staff of a limited company have rarely the same interest in their work, or at least in carrying the work out economically. Each member of the staff, though he may also be a shareholder, naturally tries to obtain as high a salary as possible. The salary is a certainty, while the dividends depend upon many independent variables. Equally also, with few exceptions, the employé, even the director of a limited company, takes care that his co-employers or co-directors do not get more work out of him than he considers they pay for. Each man, with few exceptions, conscientiously does what he considers to be his duty to his employers, or his co-shareholders, but each man also religiously does what he considers to be his duty towards himself. Another cause of increased expense is the unavoidable absence of a single directing mind. For engineering work, no matter how much it may be divided, it is necessary that there should be one single mind over all, directing the whole business, and it is even better that this mind shall have no engineering knowledge or ability at all, provided that it possesses sound commercial ability, than that there should be two or three minds all taking part in the direction; where, as in a limited company, every director has a right to meddle in every detail, and thinks he is doing his duty to the shareholders by meddling to the utmost of his ability. Where, as usually happens, everything has to come before the Board, time at least is lost, if nothing else. Valuable opportunities too, are frequently wasted, temporary and expensive makeshifts resorted to, and so on; all costing money in some form or the other, and all coming out of the profits.

In every branch of engineering, in every manufacturing business, but particularly in electrical engineering, there are times when very important decisions have to be made, often in a few minutes. Often these cases are such as could hardly have been foreseen, yet must be dealt with immediately. There is no time to call the Board together—someone must act. In a private concern, with only one partner, or with only one active partner, who has the whole details of the business at his fingers' ends, the decision is made promptly, after the few minutes' rapid thought that long experience has enabled him to act upon; and

Digitized by Google

the judgment, whatever it is, will be the best possible under all the circumstances—the one calculated to do his firm the greatest amount of good at the minimum of expense. With a limited company, in such cases the manager or managing director, unless he is a very strong man, is terribly handicapped by the fact that he will have to justify his action to his Board. If the matter turns out well, it *may* be all right. But some men are never satisfied even with the most brilliant results. They always have some tale of some friend of theirs who did better under what they consider similar circumstances. They never do any brilliant things themselves, though they are always of opinion that under proper conditions, just such as those referred to, they would have come out wonderfully. It is always their luck never to get the chances other fellows do. Given one of these men on a Board, if he is not effectually muzzled by his co-directors, and not the ablest engineer or manager that ever existed could possibly show a profit.

It will be understood, of course, that the writer by no means wishes it to be inferred that it is impossible to run a limited liability company, doing electrical engineering work, at a profit. Some concerns—such as the large electric lighting supply companies and the large manufacturing companies—must be worked as limited companies, simply because it would be impossible to attract the necessary capital in any other way. But it will be found that even these are successful just in proportion as they are carried on more and more nearly as private concerns. It will be found, without a single exception, that in those large concerns which are successful as limited companies, the power is left entirely in the hands of a very small group of able men—the smaller the number the group consists of, the better. When sufficient confidence is placed in one able man, the concern, no matter what may be its magnitude, invariably thrives best; though even the ablest of men make slips, head and eyes become tired, wrong calculations are occasionally made; yet the cost of even the great blunders of able men under such condition is far less than would be the cost of running the concern with a large number of hands on the reins.

There are a few cases, too, where even small limited companies may be run successfully. There will be cases, of course, where several men, or women, would have sufficient confidence in a man to risk a small sum, provided that they cannot possibly be made to pay more than they originally promise, and this can only be arranged on the limited liability principle. It must be borne in mind, however, that the risks of failure owing to the adoption of limited liability are in inverse proportion, other things being the same, to the size of the concern; and that it is more than ever necessary, in small limited companies, that one man should be absolute. Large concerns may thrive fairly, in spite of imperfect management, owing to outside interest exerted in favour of their companies by the very directors who are a source of expense. With small limited companies, such profitable arrangements are seldom obtainable.

There is one class of cases that should be alluded to that legitimately and naturally come under the limited liability principle. When an industrial concern has grown up from very small beginnings, in the hands of one or two families, after the original founders die, it often happens that shares in the business are possessed by members or connections of the two families, who would much rather have the cash represented by their shares. The ladies of the family, for instance, may have married men in other businesses or professions, to whom the lump sums represented by their wives' shares would be of far more service at the moment than the half-yearly dividend. Their shares are locked up in machinery, factory buildings, stock, goodwill, etc., and are not easily converted into cash. By the adoption of the limited liability principle their shares are immediately marketable.

The writer's object in the above is to endeavour to persuade young electrical engineers who are in business on their own account, and who perhaps find it hard to make a profit, not to rush into limited liability. If it is hard to make a small concern pay in the hands of one or two men putting their heads and hearts into the work with all the energy they possess, it will be impossible to make it pay as a limited company. If your business hardly pays, or does not pay, in your own hands, it is honestly worth nothing; and if you weight it with the additional capital necessary to form it into a company, and with the additional expenses, it can only go under. You may obtain a salary for a short time as managing director, and you may, if you have been very fortunate, obtain a little additional capital to play with; but it is almost an impossibility for you to obtain the capital you require, on terms other than ruinous, by turning your business into a company. Remember, too, that for every five pounds subscribed, for any five or ten pounds, at any rate, you have obtained a new taskmaster, and a hard one—possibly the agent or friend of a rival.

But the way in which the adoption of the limited liability principle has prejudicially affected the advance of electrical industries is by the cutting of prices that has been done by some limited companies, often accompanied by bad work. The necessity of keeping afloat has led them to take contracts at less than cost, and then to raise debentures on the strength of these contracts—which, of course, debenture-holders could not tell would be unprofitable. The result has been, in many cases, that the advance of electrical engineering has been retarded, because distrust has been created in the stability of the work; and in addition, everyone connected with the concern, many not connected with it, and often the whole industry, have lost heavily through the lowering of prices that ensued.

FAULTS IN DYNAMOS.

Mr. J. A. Montpelier has contributed several articles to our contemporary *L'Electricien* on this subject, an abstract of which may prove interesting. The author points out that the faults which affect the working of a central station may occur in the dynamo, in the distributing system, in the house wiring and fittings so far as the electrical part is concerned, or may occur in the prime motor. Only the faults which may affect the dynamo are considered. These are:

1. The dynamo gives no current.
2. Great sparking at the brushes.
3. Abnormal heating of some of the constituent parts of the dynamo.
4. The dynamo is too noisy and too shaky during running.
5. The armature runs too slowly.

We will examine, he says, in their order the various causes of these faults, the methods by which they may be detected, and the means by which they may be remedied.

In the case of a dynamo giving no current the fault would be due to one of the following causes:

A. Remanent magnetism in the field too feeble.

B. Defective contacts.

C. Short-circuit or bad insulation in the internal or external circuits.
- (*a*) Badly-insulated terminals.
- (*b*) „ „ brush-holder.
- (*c*) „ „ armature coils.
- (*d*) Short-circuit in the armature coils.
- (*e*) Short-circuit on the commutator.
- (*f*) Short-circuit at some point of the wiring.

D. Open circuit in the dynamo or external circuit.
- (*a*) Disconnection in the field coils.
- (*b*) „ „ internal circuit.
- (*c*) Brush not making contact.
- (*d*) Disconnection in the external circuit.

E. Reversed field-magnet coils.

With regard to A—that is, weak residual magnetism in the field—the fault is easy to detect by means of a small piece of iron held towards one of the poles, when the iron is but slightly attracted. Usually, the causes of the fault are many. It may be due to a reverse current in the field-magnet coils—such, for instance, as would result from the accidental discharge of a battery of accumulators with reversed connections, the action of terrestrial magnetism,

Digitized by Google

or the disturbing influence of another dynamo in close proximity to the first. To remedy this fault, the dynamo must be separately excited. If the defect continues, pass a second but reversed current through the field-magnet coils.

When the dynamo is series wound it is sufficient to start it, and when it has attained its normal speed to short-circuit it momentarily by connecting its terminals with a copper wire. As soon as excitation begins the short-circuiting wire must be removed, to avoid risk of damage to the machine.

When the dynamo is shunt wound another method must be resorted to, because excitation cannot be produced by short-circuiting. In this case remove the external circuit, excite as before, and replace external circuit.

B. DEFECTIVE CONTACTS.—Bad contacts in the different connections on a dynamo are only to be discovered by a close and careful examination in detail of every connection of the armature and coils, and an equally careful cleaning of the various parts. When the fault is caused by a defective contact in one or more of the fixed coils it may be detected by approaching (without contact) a piece of iron to the pole-pieces. If the contacts are good, the iron will be equally attracted by each pole-piece; but if bad, the magnetism will vary, and the movement of the iron held in the hand enable the fault to be located.

C. SHORT-CIRCUIT OR BAD INSULATION IN THE INTERNAL OR EXTERNAL CIRCUITS.—This fault is indicated in shunt-wound dynamos by a feeble but still perceptible magnetisation of the pole-pieces. To ascertain whether short-circuit exists in the internal or external circuit, the conductors should be removed from the terminals of the dynamo, and an incandescent lamp substituted for them. If the lamp burns steadily, the fault must be in the external circuit. If thenot, fault can be located in the internal circuit by the following tests:

(*a*) *Badly-Insulated Terminals.* — Insulation of the terminals should be tested by means of a battery and

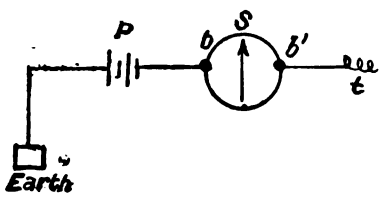

FIG. 1.

galvanometer. The battery, P, Fig. 1, is composed of three or four Leclanché cells connected in series. One of the poles of the battery is put to earth—through a gas or water pipe, for example—and the other pole is connected to one of the terminals, *b*, of a galvanometer, G. The other terminal, b^1, is connected to a loose wire, whose other extremity is successively brought into contact with each terminal of the dynamo. If the insulation is good, the needle of the galvanometer should not move. The insulation of each terminal may be found by connecting the earth lead of the battery with the base-plate of the dynamo, and then touching successively each terminal with the wire from b^1.

(*b*) *Badly-Insulated Brush-holder.*—The procedure is the same as in the foregoing test, each of the brush-holders being touched in succession with the wire from b^1.

(*c*) *Badly-Insulated Armature Coils.*—The insulation of the armature coils is ascertained in the same manner, but great care must first be taken to detach the outer wires, so as to be sure that the fault is not in the external circuit. When the armature coils are all badly insulated, and there is leakage to earth through the base-plate, the dynamo will not give current. It may be that one of the coils only is defective, in which case the dynamo will give current, but the current will be much weaker than normal.

(*d*) *Short-circuit in the Armature Coils.*—Short-circuit in the armature coils would introduce a shunt of greater or lesser resistance between certain points, and as a result an integral part of the exciting current would be absorbed between those points instead of it passing through the whole of the coil, and there would be a loss of power in the magnetic field. In series-wound dynamos the current would be weakened, and the defective coil would heat less than the one in good order. In shunt-wound or compound-wound dynamos both coils would heat equally.

To find the defective coil, a separate test should be made of the resistance of each of them after removing every outside connection. For this purpose a Wheatstone bridge and resistances, a sensitive galvanometer, and a battery of three or four cells should be employed. If this apparatus is not procurable, a battery and galvanometer connected

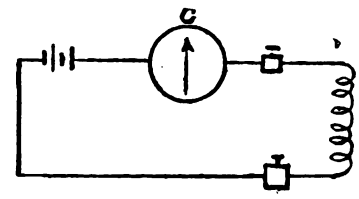

FIG. 2

with the coil in the manner shown in Fig. 2 may be substituted. The deflection given by the galvanometer with each coil should be noted. The coil in which the short-circuit exists will give a much larger deflection than the others.

(*e*) *Short-circuit on the Commutator.*—A short-circuit caused by copper dust connecting two or more sections of the commutator is sufficient to prevent the dynamo from giving current. A minute examination of the commutator, with, if necessary, a test with battery and galvanometer or bell, will always result in the detection of this fault.

(*f*) *Short-circuit at Some Point of the Wiring.*—Means of detecting short-circuit in the dynamo or the external current have already been described. To localise the fault, if it exists in the external circuit, the conducting wires which were removed from the terminals of the dynamo should be sharply replaced, and the cut-out nearest to the fault (if cut-outs are employed) will blow. Otherwise the conductor at the fault will be heated, and the insulating substance covering it will probably take fire. If the short-circuit is of serious extent it is probable that when the conductors are reconnected to the dynamo at a moment when the latter is running at normal speed, the belting will slip from the pulley. In such case the fault may be discovered with a battery and galvanometer in the following manner:

All the lamps or apparatus should be disconnected and the conductors left open. That done, the wires from the battery, P, Fig. 3, should be led—one to the point of departure of the main lead, *m*, and the other to the terminal, *g*, of a galvanometer, G. Another wire should be taken from the terminal, *g*, of the latter to the other main lead, *n*. If the circuit is in order the galvanometer

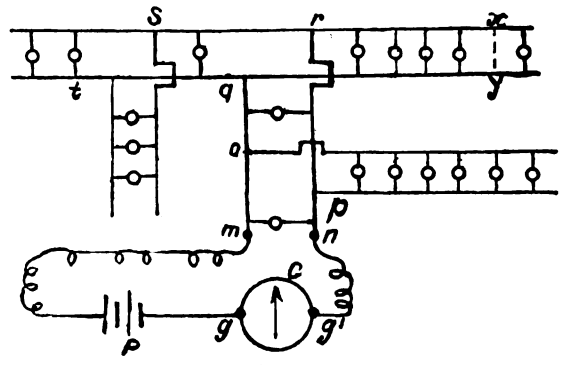

FIG. 3.

will not give any deflection—the two main leads being insulated from each other. If the circuit is faulty—supposing, for instance, that there is a short-circuit at *x y*—the branch circuits should be detached one by one—that is to say, *o p*, *q r*, *s t*—and once the fault is localised on branch *q r*, it is easy to find and repair it.

If the test shows that the external circuit is in good order, the fault must be looked for at or near the ends of the conductors nearest the dynamo, and will probably be found in the wires connecting the dynamo with the switch-board, or in the switchboard itself. A bad short-circuit,

Digitized by Google

such, for instance, as that sometimes produced by defective lampholders, will prevent the dynamo from giving current. It is very necessary to thoroughly examine and test the connections of the lamps or other apparatus in the main or branch circuits, as well as the switchboard, before reconnecting the main leads to the dynamo; and whenever short-circuit is indicated in the external circuit, the dynamo should be disconnected until the fault is localised and repaired.

REDUCING THE CAPACITY OF LONG-DISTANCE TELEPHONE LINES BY MEANS OF SELF-INDUCTION.

BY DR. MAX REITHOFFER.

It has frequently been observed on long-distance telephone lines (Vienna-Prague, or Vienna-Trieste) that the transmission between the two terminal stations is very much improved by cutting into the main line one or several way stations possessing self-induction. Indeed, the transmission between Vienna-Prague is greatly improved by introducing into the main line the way stations Brunn, Iglau, Kolin, and, as a matter of fact, each sub-station is found to improve the clearness of transmission.

This phenomenon is attributable to the large capacity of the line in consequence of which the charging currents overpower the talking currents. On account of the great resistance of the line, there is, of course, a considerable fall of potential; in other words, the variable E.M.F. set up at the transmitting station arrives greatly weakened at the distant station, and this attenuation of the legitimate talking currents is accentuated by the existence of capacity on the line. To improve long-distance transmission, we must cast round for means to neutralise the charging currents, or to cut them down as much as possible.

FIG. 1.

It is well known that the current received by a condenser, placed between points A and B of a line supplied with alternating currents, shows a phasal difference of 90deg., while the current passing through a coil with self-induction in parallel with the condenser at points A and B, lags by an angle ϕ, whose tangent is tan $= \frac{2 n \pi l}{r}$ (n = number of periods; l = coefficient of self-induction, and r = wire resistance).

If it were possible to make ϕ = 90deg., the two currents would be in opposite phases, and by equalising their amplitudes, their combined current would neutralise one another. In reality, such a phase difference (180deg.) can only be approximated, and the resulting current may be made very small, but can never equal zero; thus the loss of potential of the line becomes insignificant and the legitimate current increases.

It is desirable to find some means for strengthening the talking currents of long-distance telephone lines. A telephone loop may be replaced by two lines having no capacity, but a number of small condensers in parallel branch between the two conductors. Again, we may replace a number of such condensers by a single one inserted exactly in the middle of the two conductors, and having a capacity eqnal to one of them.

M represents the sending, N the receiving station; T and T' are telephones, s and s' the secondaries of the transmitter induction coils; C the condenser of a capacity equal to that of the loop.

For the purpose of our consideration we assume that the E.M.F. of the secondary at M is known, and varies in accordance with the law of sines, the mean period being N = 500.

It would not be a difficult task to find the exact current passing through the telephones at the receiving station, but as we desire only approximate figures, it seems best to make a general computation, having in view some definite data, and to this end we will base our computation on the line Vienna-Prague (320 kilometres).

The exact data of this line are as follows:

Resistance of loop = 1,400 Ω.

Resistance of one second transmitter induction coil = 180 Ω.

Resistance of one telephone coil = 200 Ω.

Coefficient of self-induction of one of the secondary transmitter induction coils = 0·7 h.

Coefficient of self-induction of one telephone = 0·1 h.

Capacity of loop = 3 microfarads.

Designating by R the resistance of that part of the line on the right side of A B; the sum of the coefficients of self-induction by L; calling R_1 the ohmic resistance of the line on the left of A B; L_1 the sum of the coefficients of self-induction, and not taking into account the second transmitter induction coil at M, we have

$$R = 1{,}280\ \Omega. \qquad R_1 = 1{,}280\ \Omega.$$
$$L = 0{\cdot}9\ h. \qquad L_1 = 0{\cdot}2\ h.$$

We will now compute the current, i, which starting from N reaches the telephones, assuming that C is between A and B, and is itself shunted by an induction coil. In this case the effect of C is materially weakened, and we may commence our computation by considering the effect of C as being suppressed, or as there being no condenser.

In the first case, to find the relation between the E.M.F., e, in M and the current i, we consider $\delta = \Delta \sin w t$, the potential at the terminals of the condenser. If $w = 2 n \pi = 1{,}000 \pi$, we have

$$\tau_1 = \frac{\Delta}{\sqrt{R^2 + w^2 L^2}} \sin (w t - \phi) = J_1 \sin (w t - \phi).$$

The apparent resistance of the right part of the cone $\sqrt{R^2 + w^2 L^2}$ may be R^1 or $R^1 = 3{,}120$. Consequently,

$$\Delta = J_1 R^1 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$
$$\delta = J_1 R^1 \sin w t \quad . \quad . \quad . \quad . \quad . \quad (2)$$

and the current, τ_2, passing through the condenser is

$$\tau_2 = C \frac{d \delta}{d t} = w C \Delta \cos w t \quad . \quad . \quad . \quad (3)$$

Inserting in this equation the value of Δ as given by (1), we have

$$\tau_2 = w C R^1 J_1 \cos w t = J_2 \cos w t \quad . \quad . \quad (4)$$

In other words, whether or not the charging current, ϵ_2, is stronger than the legitimate current, τ, depends solely on the quantity $w C R^1$. In our computation this product is equal to 29·4, or the condenser current is 29·4 times as large as the talking current.

To find the resulting current, i, we must venture τ_1 and τ_2. For an approximate first computation we may well neglect τ_1 and thus work

$$\tau = \tau_2 = (w C R^1). \quad J_1 \cos w t \quad . \quad . \quad (5)$$

An accurate computation decreases the value of τ (28·5 J_1, instead of 29·4 J^1), and the current lags 1 – 2 degrees compared with τ_2.

From δ_1 and τ the relation between E and J_1 are easily established.

$$e = \delta + \tau \sqrt{R_1^2 + w^2 L_1^2},$$

but $\sqrt{R_1^2 + w^2 L_1^2}$

is the apparent resistance of the left portion of the loop, R_1, its value being 1,430.

Now using equations (2) and (5) we have

$$e = J_1 R^1 \sin w t + J_1 R^1 w C R_1^1 \cos w t \quad . \quad (6)$$

Again taking $e = E \sin (w t + \phi)$ then

$$E = J_1 R^1 \sqrt{1 + (w C R_1^1)^2} \quad . \quad . \quad . \quad (7)$$

But as $(w C R_1^1)^2 = 180$ we may neglect (7) and write

$$E = J_1 R^1 w C R_1^1 \quad . \quad . \quad . \quad . \quad (8)$$

or,
$$J_1 = \frac{E}{w C R^1 R_1^1} \quad . \quad . \quad . \quad . \quad . \quad (9)$$

or, expressed numerically,

$$J_1 = \frac{E}{42{,}000} \quad . \quad . \quad (10), \text{ and } = \Delta \frac{E}{13{\cdot}5}.$$

Digitized by Google

But if there is no condenser we find the current directly considering merely the entire apparent resistances—*i.e.*,

$$J_1 = \frac{E}{\sqrt{(R + R_1)^2 + w^2 (L + L_1)^2}} \quad . \quad (11)$$

expressed numerically,

$$J_1 = \frac{E}{3{,}480} \quad . \quad . \quad . \quad (12), \text{ and } \Delta = \frac{E}{1{\cdot}11};$$

or the intensity of the current without a condenser would be twelve times as great, a conclusion independently arrived at by Dr. Sakulka.

The percentage loss in potential from M to A B—*i.e.*, $\frac{E-\Delta}{E}$ ·100 as in the first case 92·6 per cent., in the second 9·9 per cent. However, as it is impossible to neutralise the charging currents entirely as we have assumed, the increase in the talking current will not be quite as good. Again—as see equation (9)—l appears in the denominator, the first current arrangement becomes more disadvantageous with an increase in capacity.

It should be borne in mind that a decrease of the condenser effect increases not only the amplitude of the transmitted waves, but affects also materially their distinctness; and this is most pronounced with compound waves or undulations, such as are produced in voice transmission.

This fact depends in both equations on the value of w; in other words, the amplitudes, J_1, of the respective currents must correspond to the number of vibrations, n. Transmitting compound vibrations, the amplitudes of the single component vibrations on arriving at the distant station have been changed or modified. Graphically represented, the curve of the current at the transmitting station arrives at the receiving terminal station in a distorted condition, such distortion increasing with the more or less pronounced effect which the number of vibrations has on the amplitude of the current.

Considering now equation (11), the influence of w may be insignificant, the value of R and R_1 being great; on the other hand, imagining the most disadvantageous condition, w remains a linear function of the denominator. Using a condenser—compare equation (9)—J_1, in its most favourable condition, will be inversely proportional to w, and in its most disadvantageous condition inversely proportional to w^3, because w is a factor of R^1 and $R_1{}^1$; in other words, the clearness and distinctness of voice transmission is greatly aided by suppressing the condenser effect of a telephone loop.

But in order to cut down the condenser effect by shunting the line with the secondary of an induction coil two conditions are required.

The current phase of the coil must lag 90deg. behind the phase of the E.M.F., and its amplitude must equal that of the condenser. Signifying by l and r, respectively, the coefficient of self-induction and resistance of the coil, we have $w\,l$ large as compared with r, because $\tan \phi = \frac{w\,l}{r}$, and

$$\frac{1}{\sqrt{r^2 + (w\,l)^2}} = w\,C.$$

It is sufficient to make $\tan \phi \geqq 10$, and $w\,l \geqq 10\,r$; we now have for our second equation

$$\frac{1}{w\,l} = w\,C, \text{ and for } l = \frac{1}{w^2\,C} \quad . \quad . \quad . \quad (13)$$

For our computation we require a self-induction of about 0·034 h, and a resistance less than 10 Ω. We also assume that the coil has no iron core. Hysteresis and Foucault currents decrease the phasal difference, and if iron cores are used they should be laminated.

In fact, a coil in which $w\,l$ is great compared with r may be considered a condenser of negative capacity, its value being $C_1 = -\frac{1}{w^2\,l}$. Placing such a coil in parallel current with a condenser, C, it may be said that such an arrangement represents another condenser, C_0, whose capacity is

$$C_0 = C_1 + C, \text{ or } C_0 = C - \frac{w^2\,l}{1} \quad . \quad . \quad . \quad (14)$$

In case l is equal to $\frac{1}{w_2 C}$, C_0 must approximate zero. Equation (14) shows how a coil with different values of self-induction may be advantageous or injurious.

Our entire computation so far has been based upon the assumption that the entire capacity of the line may be replaced by a condenser inserted in the middle of the line. It stands to reason, however, that we shall better approximate the real conditions of a commercial line if we insert a number of condensers of small capacity between the out and return conductors of a loop. For instance, we might at each 10 kilometres distance place coils whose constants had been computed for the capacity of 10 kilometres of conductor. Such an arrangement, according to Preece, would diminish the capacity of the loop, its characteristic product becoming smaller.

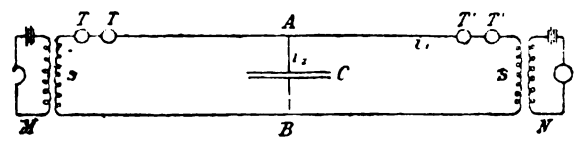

Fig. 2.

The same considerations which we have applied to a loop hold good for a grounded line.

It will be remembered that long ago De la Touanne, while constructing the aerial telephone line between Paris and Rheims, called attention to the improved transmission over a long-distance line brought about by inserting in parallel circuit coils having self-induction. The same phenomenon was noticed by Cailho, in 1890, on the cable between Calais and Dover. But all these arrangements differ from the one here described by inserting the self-induction as a shunt, at the terminal stations; on the contrary, we assume that the self-induction is placed in the centre of the line, or in several intermediate stations.

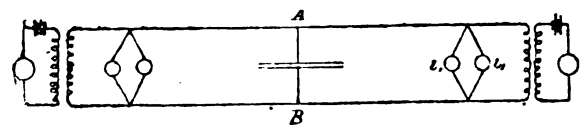

Fig. 3.

Both Cailho and De la Touanne committed the mistake of using coils with an excessively large self-induction; thus they concluded that the smaller the coefficient of self-induction of the coil or coils, the more advantageous would be the use on a long line; but equation (14) shows that by going below a certain value the opposite result takes place.

Cailho made experiments on the line Paris-Beauvais, placing the telephones in a shunt, either in series or in parallel, and he claimed that such an arrangement produced an improved transmission. This phenomenon does not depend, however, so much upon a weakening of the charging currents as upon a favourable arrangement of the circuit resistance. In fact, such an arrangement may advantageously be employed for lines having a large capacity and comparatively small resistance.

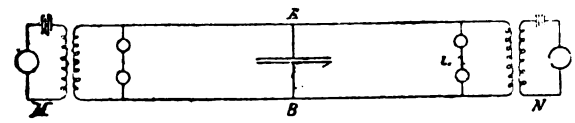

Fig. 4.

In his experiments with the 80 kilometres underground line Paris-Beauvais, Mr. Cailho employed the following values:

Resistance of the loop, 1,340 Ω.
Capacity of each condenser, 15·6 microfarads.
Coefficient of self-induction of one telephone, 0·15 h.
Resistance of one telephone, 200 Ω.
Resistance of the secondary of the transmitter induction coil, 150 Ω.

The coefficient of self-induction of the secondary of the transmitter induction coil is not stated; we assume its value to be 0·7 h.

Again, using our simplified equation—*i.e.*, replacing the

Digitized by Google

capacity of the entire loop by a single conductor inserted in the centre of the line—we may represent this new arrangement by Figs. 3 and 4.

Omitting for the present in our computation the capacity of the entire line, we have the following values for J_1, the amplitude of the current in the telephones at the receiving station :

$$\left.\begin{aligned} \text{By Fig. 2, } J_1 &= \frac{E}{4{,}750} \\ \text{,, } 3, J_1 &= \frac{E}{4{,}500} \\ \text{,, } 4, J_1 &= \frac{E}{2{,}780} \end{aligned}\right\} \quad . \ . \ . \quad (15)$$

It is evident that cutting the high apparent resistance of the secondary of the transmitter induction coil out of the telephone circuit is advantageous in the circuits shown in Figs. 3 and 4 ; in fact, the secondary constitutes there a relatively high shunt to the telephones. On the other hand, the transmitting station is not so favourably affected by the existence of a local circuit, constituted by the telephones in a parallel branch with the main line. In other words, only a portion of the E.M.F. originated at the transmitting station affects the line. Nevertheless, the final result demonstrates the advantage of such disposition, and the latter becomes more advantageous by a consideration of the large capacity of the line—*i.e.*, 31·2 microfarads. A condenser of capacity C (besides its effect upon the phase of the current) represents a resistance of the value $\frac{1}{w C}$, but

$$C = 31{\cdot}2\ 10^{-6} f \text{ or } \frac{10^6}{2 n \pi\ 31{\cdot}2} = 10{\cdot}2\ \Omega,$$

or a relatively small resistance. Again, in all three circuit arrangements the charging currents are 80 times as great as the telephone currents, and we see that the advantages of arranging the circuit, as shown in Figs. 3 and 4—*i.e.*, cutting down the resistances in the telephone circuit proper—remain undisturbed, while the disadvantages—loss of charging currents—become less important.

Setting aside the somewhat involved mathematical deductions, we will at once state their results in which Δ expresses the potential at the condenser terminals, and J^1 the amplitude of the arriving telephone current :

$$\left.\begin{aligned} \text{By Fig. 2, } \Delta &= \frac{E}{151} \ ; \ J = \frac{E}{509{,}000} \\ \text{,, } 3, \Delta &= \frac{E}{100} \ ; \ J = \frac{E}{178{,}000} \\ \text{, } 4, \Delta &= \frac{E}{83{\cdot}2} \ ; \ J = \frac{E}{132{,}000} \end{aligned}\right\} \quad . \quad (16)$$

Equation (16) shows that although in (3) and (4) amplitude of the charging currents is larger, there is less loss of potential on the line up to the condenser. On account of the decreased resistance of the telephone circuit, the arriving telephone currents are greater than the increase of potential, Δ, would indicate. A comparison between the values of (15) and (16) proves conclusively how injuriously a telephone line is affected by its capacity ; also how much the talking currents are strengthened by reducing the condenser effect by means of suitable self-induction.—*Electrical Review* (New York).

INSTITUTION OF ELECTRICAL ENGINEERS, Jan. 11.

INAUGURAL ADDRESS OF MR. ALEXANDER SIEMENS, M.I.C.E. (PRESIDENT).

In taking this chair, and in thanking you sincerely for having elected me to be your President during this year, it is only natural that I should remind you of the fact that the late Sir Wm. Siemens was your first President. For this reason I may claim to be the first representative of the second generation of electrical engineers who have been called into separate existence by the founding of this Institution 22 years ago. During this period the Institution has grown from small beginnings to its present flourishing condition, thanks to the ability and energy of its founders and of my predecessors in this chair, who have spared neither time nor trouble to secure for electrical engineers the position to which the growing importance of the applications of electricity entitles them. In these endeavours they have been most ably assisted by the permanent staff of our Institution ; but the greatest aid has been the benevolent friendship of the parent institution and its officers.

The permission to use this hall for their meetings started the Society of Telegraph Engineers with a standing in the engineering world that it would have cost years of work to achieve elsewhere ; and the kindly counsel of the veteran secretary of the Institution of Civil Engineers has often guided the society in times of difficulty during the period of infancy, and we sincerely hope that he will long continue his useful work in this building. The contrast which exists in the applications of electricity at the time of the founding of this Institution and at the present time has been so clearly and ably put forward by Mr. Preece in his address last year, that it would be wasting your time if I entered into any details to illustrate the progress. On the other hand, it may not be out of place to analyse the various factors which have influenced the development of our profession from the time at which telegraphy was the only important practical application of electricity, until now, when it is called upon to supply energy for an immense variety of purposes.

During the past 22 years our profession, and with it the Society of Telegraph Engineers, have changed their character, until these and the scope of their activities have become much more comprehensive, and much more intimately connected with the everyday life of the general public. With reference to this, telegraphy may be compared to the railways, as they both are for the indiscriminate use of the general public, and it is only an exception if a railway or a telegraph line is constructed for private purposes only. For working both these lines a special staff is required, and general rules for their use have to be adhered to by everybody ; while in the modern applications of electricity the chief aim is to distribute the electrical energy so that each individual user can apply it in the manner and during the time that it best suits his convenience.

I need not recapitulate the reasons which for a long time made this distribution of electrical energy commercially impossible ; but when these difficulties had been overcome, and the electrical engineers were ready to supply the public, it was found that, excepting the Corporation of the City of London, there existed no authority in the United Kingdom that could permit the laying of underground mains, and that a special Act of Parliament was requisite. To the unsophisticated mind this appeared to be extremely simple, as all that was needed was to extend the powers of the various authorities to whose care the laying of water and gas pipes and of telegraph lines was entrusted, so that they could deal in a similar manner with electricity mains. Some of the electric light companies were of opinion, however, that the same object would be attained if they received powers from Parliament to make agreements with the local authorities, subject in every case to the approval of the Board of Trade, for establishing a system for distributing electrical energy in the various districts ; and in pursuance of this policy several private Bills were filed for the session of 1882.

The Government of the day did not consider it to be of public advantage that a limited number of electric light companies should have such roving powers, but brought in a general Bill with the intention of facilitating and expediting the general application of electricity.

With this object in view, powers were to be given under the Bill to the Board of Trade to grant licenses or provisional orders to electric light companies.

The license to establish a system of electrical distribution in any district was to be granted to an electrical company who had succeeded in gaining the consent of the local authority ; and its conditions were to be settled between the local authority and the company, subject to some general provisions to be drawn up by the Board of Trade, and subject to the sanction of the Board of Trade.

In districts where the local authority objected, the elec-

Digitized by Google

tric light company should, nevertheless, be able to establish itself by means of a provisional order of the Board of Trade; but to obtain this the company had to prove that the majority of the inhabitants of the district desired to have facilities for obtaining electrical energy. It will be observed that in this draft the license was intended to be the usual way of obtaining power to lay underground mains, and the formalities for settling it were extremely simple; the provisional order, on the other hand, was to be resorted to in exceptional cases as a means of overcoming the objection of local authorities. This is confirmed by the fact that in the draft the duration of the license and of the provisional order were equal.

These benevolent intentions were, however, thoroughly upset during the passage of the Bill through Parliament, and the Electric Lighting Act (1882), which was the outcome of the discussions before a Select Committee, has given rise to angry denunciations on account of the obstacles which, in the opinion of many, it was raising to an early introduction of lighting by electricity on a large scale. Curiously enough, nobody during the passing of the Act, or afterwards, seemed to care much about the fate of the licensing system, which was completely stripped of its importance, and alluded to by the learned counsel on both sides as suitable only for experimental purposes. Following up this train of ideas, the duration of a license was curtailed to seven years.

Had the intention of the Government, however, been carried out as at first designed, we should now enjoy in the United Kingdom the same facilities of establishing electric supply systems that have aided the development of the electrical industries so much in other countries, instead of being obliged to apply to Parliament in each separate instance, at great trouble and expense. Disregarding entirely this vital alteration of the Bill, another provision was seized upon to explain the failure of so many electric enterprises to which the aid of the public had been invited about that time. You all know that this was the clause giving the local authority the right to buy out the electrical company after the lapse of 21 years, paying only the market value of the plant. This agitation was continued until, seven years later, the objectionable clause was modified, and in consequence of this alteration it was said that the confidence of the public in electrical enterprises had been restored. At the same time, the system of granting powers by way of a license was practically dropped altogether, and since then the Board of Trade has declared its intention not to grant provisional orders to electric light companies unless they have obtained the consent of the local authority, thereby abandoning entirely the original object of the provisional orders. The ultimate result of all this legislation has, therefore, been to create a number of difficulties in the establishment of distributing systems in the United Kingdom; in fact, the formalities of applying for a provisional order are very similar to those required for a private Bill, so that practically we are not in a very much better position than before the passing of the Electric Lighting Act, 1882.

In order rightly to understand the influence which this legislation exercised on the development of the electrical industry, it is necessary to examine into the character and the number of the applications made to the Board of Trade under these Acts, and to trace how many of them have led to the establishment of distributing systems. Taking first the case of the electric light companies, or, as the Act calls them encouragingly, "the undertakers," we find that in 1883, 55 provisional orders were granted, all of which have been revoked; in 1884, three provisional orders and one license were granted, all of which have been revoked; in 1885, one license was granted for the lighting of St. Austell, and this has been put into operation; in 1886, one provisional order was granted to the Chelsea Electricity Supply Company: this also has been carried out; four licenses granted during the two following years, 1887 and 1888, have since been revoked; so that, up to the time of the passing of the amending Act (1889), one license and one provisional order are the sole survivors. These facts clearly indicate that under the Electric Lighting Act, 1882, the undertakers have not succeeded in their object to make electrical energy obtainable as a household commodity. It is, of course, quite another question whether there were not very strong causes of another kind which prevented the powers obtained under the Act from being exercised.

Since the Electric Lighting Act, 1889, was passed, a new impetus was given to these enterprises, and, without examining the result of each year's applications separately, the grand total of the undertakers' efforts is that since 1882 138 provisional order have been applied for, and 15 licenses; of these, 81 provisional orders and nine licenses have been revoked, so that 57 provisional orders and six licenses are still in force. To this number two provisional orders have to be added, which have been transferred from local authorities to undertakers. An electric supply has been established, or the work is actually taken in hand, in 54 cases, and about 53,000 h.p. will be available. On the other hand, of local authorities, a few had obtained powers under special Acts. The City of London, as mentioned above, had been able to make some experiments of street-lighting without any special permission; but a number of them availed themselves of the opportunity given by the Electric Lighting Acts, and obtained 121 provisional orders and six licenses up to the end of last year. Of this number eight provisional orders and four licenses have been revoked, or merged in provisional orders, so that 113 provisional orders and two licenses granted to local authorities are still in force; but two of the provisional orders have been transferred to undertakers, as mentioned above. Under these powers, 51 electrical systems of distribution, with 35,000 h.p., have been established or are in course of construction, while in almost all the other instances the intention soon to carry out the work is apparent. With your permission, a table, giving the details of all these applications and of their fate, will be added to the address, if you consider it worthy to be printed in the *Transactions* of our Institution.

From the figures which I have given, it is, however, plainly apparent that the local authorities will very shortly have a good many more stations at work than the electric lighting companies; and, in my opinion, this is as it should be. The financial success which has invariably attended the municipal electric enterprises has relieved the rates at the expense of the wealthier classes in a perfectly legitimate manner, and the more electricity becomes one of the common necessaries of life, the better it is that its supply should be in the hands of the community, and not in those of monopolists.

A strange fact in connection with this subject is that the great majority of the local authorities should have waited until the passing of the Electric Lighting Act, 1889, before applying for powers to supply electricity, for it must not be forgotten that their position was in no way affected by the alteration of the Electric Lighting Act, 1882. The explanation must perhaps be looked for in the exaggerated expectations that were raised by the statements of company promoters in the year 1882, when the most reckless assertions were made as to the results to be obtained by establishing electric systems of distribution. The natural consequence was that the enquiries set on foot by various local authorities in no way confirmed the sanguine estimates that had been dangled before the public to obtain its support; and the total failure of the electric light companies to carry out a single one of the orders and licenses obtained by them in the years 1883 and 1884, made the local authorities hesitate before they embarked the ratepayers' money in such precarious undertakings.

Fortunately, for the progress of our industry, there were some corporations who could be convinced by the result of their enquiries that the use of electric light would be very advantageous for a variety of purposes, and that the knowledge and ability of the electrical engineers had progressed sufficiently to make a profitable distribution of electricity from a generating centre possible. We have seen that their example has been largely followed, and there is every prospect of a continuous and ever-increasing development of this branch of electrical engineering. To be sure, in foreign countries, especially in the United States, the use of electricity is much more common than here; but this is the natural outcome of the greater facilities for establishing centres of supply under the laws of the various countries, where the local authorities in the majority of cases have

Digitized by Google

the power to make agreements with electrical companies for supplying the district with electrical energy for various purposes.

Another important factor in retarding the spread of the applications of electricity in this country is the otherwise very laudable desire of the electrical engineers to show in every new undertaking a distinct advance on its predecessors. In this way the details of construction are undergoing a constant change—in strong contrast to the United States, where the leading manufacturers have their standard sizes of plant and accessories; these are manufactured wholesale by specially-designed machinery, and can therefore be supplied much more cheaply than apparatus specially constructed for each case. At the same time the whole transaction is greatly simplified by the absence of long negotiations about the construction of the apparatus, the town which is to be lighted simply specifying how many incandescent lights and arc lights are to be supplied.

This system of working has certainly been instrumental in accelerating the introduction of electricity for a variety of uses throughout the States; but it can hardly be pretended that such a cast-iron application of the same apparatus under a variety of circumstances can lead to the most economic results, nor has it been possible to keep up the quality of the work to the English standard. Those of you who have visited the World's Fair at Chicago last year, and have examined a little into the details of workmanship and design, will doubtless agree that Sir Richard Webster was fully justified, in his address to the Society of Arts, in contrasting the American and the English exhibits in this respect, very much in favour of the latter. However much other causes may have contributed to delay the development of electrical engineering, it is clear that the principal one must be looked for in the exaggerated expectations that were raised, either by ignorance or design, when the general public first seriously thought of regarding electricity as a commodity for everyday use. At that time the promoters of electric companies preached to the public that electricity was in its infancy, that the laws of this new science were totally unknown, and that wonders could be confidently expected from it. There was a short time of excitement to the public and of profit to the promoters; then the confidence of the public in electricity was almost destroyed, and could only be regained by years of patient work.

That the electrical industry was not altogether killed by all these adverse factors is undoubtedly due to the firm scientific basis on which it rests, and to the advantages which the applications of electricity possess as compared with other means for accomplishing the same ends. In a discourse before the Royal Institution I had an opportunity of reminding the audience that during the last 60 years the most eminent scientific men have studied the phenomena produced by electricity, and that, in consequence, the laws which govern electric currents were perfectly well known when the supply of electricity on a large scale became commercially possible. Since that time the study of electrical phenomena has been carried on with even greater zeal than before, and electrical engineering is now in no danger of lagging behind for want of theories, but is largely aided in its progress by the painstaking investigations carried on in many laboratories, both in England and abroad. While electrical engineering is thus closely allied to physical science, it has quite as intimate a relation to mechanical engineering; in fact, its real progress dates from the time when the close connection of electrical and mechanical engineering was thoroughly recognised; and since then these two branches of engineering have reacted on one another to their mutual advantage.

The contrast between present practice and that of the pioneers of our profession is at once recognised in reading the first papers and reports on dynamo-electric machines, where particular stress is laid on the small size and on the low weight of a dynamo to produce a given result; but the necessity of having the moving parts durable, and of not always working the machine up to its maximum power, was completely ignored in the desire to produce a large effect with the minimum expenditure of materials. A glance at a modern dynamo, especially when it is built on the same lines as a machine of 20 years ago, will at once reveal the progress of mechanical design that has taken place in the interval. The circumstance that at first only weak currents of electricity were utilised for practical purposes, and that during this period the electrical appliances were constructed like scientific instruments, had undoubtedly brought about this neglect of mechanical considerations, and a healthy reaction could only take place after the mechanical engineer had taken the management of the applications of electrical energy from the hands of the physicist.

On the other hand, the requirements for driving dynamos to the best possible advantage have served as no mean incentive for mechanical engineers to introduce a number of important improvements into the design of steam-engines; in fact, the class of high-speed economical engines may be said to have been called into existence by them, and this has led to the use of direct-driven dynamos, in which this country undoubtedly has taken the lead. In another direction the governing of the speed of the steam-engines has been vastly improved, although at first the mechanical engineers regarded the complaints of the electrical engineers simply as an excuse to shift the blame for the bad performance of their dynamos on to the steam-engine. They very soon learned, however, the importance of running at an unvarying speed, and the result is that even comparatively cheap steam-engines can be obtained nowadays that govern infinitely better than a high-class engine of 20 years ago.

(To be continued.)

At last night's meeting of the Institution, after the formal business of reading and signing the minutes, the retiring **President** presented the premiums to Mr. Sayers and Mr. Cooper, and then introduced the new president, Mr. A. Siemens. Then **Sir D. Salomons**, rising, proposed a hearty vote of thanks to the retiring president, which was seconded by **Mr. Crompton**, carried, and duly responded to.

The following candidates were balloted for and elected:

Foreign Members.—Prof. Paulo Benjamin Cabral, Inspector-General of Telegraphs, Lisbon; Prof. Carhart, Michigan University, Ann Arbour, Michigan, U.S.A.; Samuel Insull, the Edison Electric Light Company, Chicago, U.S.A.; F. Jacques, the Western Union Telegraph Company, San Francisco; Dr. Claudiano Luiz Pinna, Pernambuco, Brazil; Arnold von Siemens, 94, Markgrafen-strasse, Berlin; Wilhelm von Siemens, 94, Markgrafen-strasse, Berlin; Carl Albert Unbehaun, Telegraph Department, Adelaide, South Australia.

Member.—Lester Bruce Betts, Maitland Lodge, Bournemouth.

Associates.—Robert J. Anderson, Eastern Telegraph Co., Suez, Egypt; Albert Barron, "Woodmancote," Lyndhurst-gardens, Hampstead, N.W.; Francis James Blake, 43, Clifton-hill, St. John's Wood, N.W.; William Boyd, 61, Trigon-road, Clapham-road, S.W.; Christopher J. Cummins, 12, Lower Abbey-street, Dublin; J. Birnie Evans, 29, Montague-road, Richmond, Surrey; Robert Charles Frewer, 9, Guion-road, Parson's Green, S.W.; J. K. Gibson, Eastern Extension Telegraph Co., Port Darwin, South Australia; Ernest Alfred Giles, Eastern and South African Telegraph Co., Zanzibar; Alfred T. Hailey, 26, Sloane-street, S.W.; Alfred John Harrison, Hermitage Works, Richmond; Clifford Hawkes, 22, Old-steyne, Brighton; Joseph Alexander Jeckell, Borough Electrical Engineer, South Shields; Walter C. Lang, Eastern Telegraph Co., Suez, Egypt; H. A. McCausland, 122, Sinclair-road, Kensington, W.; Herbert Henry Oswald, 15, Guildford-street, Russell-square, W.C; David Paisley, Edison and Swan United Electric Light Co., Limited, Ponder's End, N.; Arthur Portelli, Malta; William Pearson Richmond, Green Bank, Colne; Thomas Rooke, care of A. H. Preece, Esq., 39, Victoria-street, S.W.; Sydney G. C. Russell, 19, Lombard-street, E.C.; Arthur Leighton Stevens, 33, Pyrland-road, Highbury; Ronald H. Streatfield, 59, Charlotte-street, Portland-place, W.; Howard George Tozer, 11, Bridge-street, Northampton; Alfred T. Warren, 6, Aytoun-road, Brixton, S.W.

Students.—Arthur Anstruther-Thomson, Charleton, Colinsburgh, Fife, N.B.; Noel Broomhall, 2, Pyrland-road, Mildmay, N.; Sidney Phillips Doudney, Faraday House, Charing Cross-road, W.C.; George F. Heron, 14, De Vere-gardens, Kensington, W.; David Martin, 1, Provan-place, Govan, near Glasgow; Hugh Bernard Maxwell, Faraday House, Charing Cross-road, W.C.; Chas. Stanley May, Gower's Farm, Braintree, Essex; Frank John Rynd, Faraday House, Charing Cross-road, W.C.; N. B. Rosher, 33, Edith-road, West Kensington, W.; George Swetenham, 5, Inglis-road, Ealing, W.; Charles Percy Taylor, Westfield House, Bishop Stortford; Ralph Waldo Webster, Granville House, 90, Angel-road, Brixton, S.W.; George Edward Wright, Barclay-road, Croydon; R. J. C. Wood, 24, Sinclair-road, West Kensington, W.

At the conclusion of the Presidential Address, **General Webber** moved, and **Prof. Robinson** seconded, a vote of thanks to the President for his address, which was carried with acclamation.

At the next general meeting Mr. Preece will read a paper on his late visit to Chicago.

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XI. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

THE TENDENCY OF BUSINESS.

In our remarks last week we referred to the views expressed by Mr. Mordey as to the tendency of business, especially installation work, to be placed in the hands of one responsible authority, rather than for a number of contractors to be engaged, each, so to speak, responsible, yet no one responsible for the work as a whole. The desirability of personal responsibility for the work as a whole has long been one of our contentions, and we are glad to see it receiving almost universal acceptance. It is well known, also, that we are strong advocates of the employment of a consulting engineer, although Mr. Mordey may not agree with us on that point. At any rate, some of the principals of large companies rather prefer to design their own work and carry it out than to work to the design of an independent authority. But for the present we shall restrict our remarks to the question of personal responsibility. Mr. W. B. Esson, commenting on Mr. Mordey's remarks in a letter to us, says: "With reference to some remarks anent the gradual drift of particular kinds of business to particular manufacturers, and the sub-division of the trade into central station, isolated plant, small accessories, and wiring firms respectively, this was inevitable, and the fact denotes the approach of the final stage of the evolution of the industry. But one of the factors which has been not a little influential in quickening the development lies in the circumstance that the larger businesses have always had at call, through the influence of their Boards, a large amount of capital, and have thus been able to promote the forming of supply companies, and to take payment of the contracts they have carried out part in shares instead of cash. It is probable that the large manufacturing concerns will become in future simply electric supply trusts, with a factory tacked on, and an examination of several balance-sheets shows that this is more or less the case already. In the extent to which this obtains, I believe the electrical industry is quite unique."

This aspect of the matter is correct so far as it goes. The command of capital, and the ability to float sub-companies, has been an enormous advantage to some of our largest concerns, but in the evolution of the industry a turn is being taken that will remedy the evil brought about by subsidiary companies, and gradually the shares now held of such companies will be wiped out of balance-sheets. Before showing that this is so, we must insist that the welfare of the industry has been largely brought about because of the opportunities mentioned. Had not the large companies which could command capital *made* business rather than let it come to them, the progress would not have been half so rapid; and men would have waited—they are waiting now in many instances—because the "electric light was," or, as they argue, "is in its infancy." This fallacy has been knocked upon the head, thanks to the commercial energy and foresight of the principals of the big companies and the ability of their colleagues the engineers. A few years since many of the men who are now the strongest

Digitized by Google

advocates for the action of local authorities were opposed to such action. When the local authority takes up the work the command of capital to form local companies is not wanted, nor is there any share capital of the subsidiary company found in the parent company's balance-sheet. It is in this direction that a change has come, and in the future will be more accentuated. There was a limit even with the strongest syndicate in forming sub-companies, but by this means they obtained a commanding position in the industry, and can now use that position to good account. What is an objection the smaller firm or the beginner has continually to face? Is it, as usually stated, the not having carried out similar work? There is always a lack of haste to give large work to inexperienced firms; hence those who have *made* their experience must, in the natural order of things, obtain first consideration from customers. The work done and the shares which figure upon the balance-sheet show so much capital sunk in obtaining a "goodwill," and "goodwill" under certain conditions is an extremely valuable asset. It may be made too much of, but that is another question.

BUSINESS DURING 1893.

(Continued from page 26.)

The BRUSH ELECTRICAL ENGINEERING COMPANY, LIMITED, have during the past year had their works employed upon all classes of electric lighting contracts, particularly those for plant for central electric lighting stations. The large and important contract for lighting the city of London has made great strides towards completion during the past year, there being now delivered at Bankside station (in addition to the plant originally put down there) six sets of Raworth-Mordey combined alternating plant, with an aggregate output of 2,500 kilowatts, and the equipment of the various transformer stations is now fast approaching completion. The original contract for lighting the town of Huddersfield has now been completed, and orders for considerable extensions have already been received. Additional plant has been supplied for the central stations at Sheffield, Bournemouth, Hastings, and Woking. Among the other central-station contracts secured during the past year may be mentioned those of Leicester, Lancaster, Dover, Canterbury, Fleetwood, Coatbridge, and those for the supply of alternators and arc lighting plant to the Great Northern Railway Company, Holloway, and to Hastings and Blackpool for lighting the promenades on the sea-front; alternators, exciters, and transformers to the Bolton Corporation; the complete equipment of the transformer sub-stations for Bristol; and the supply of alternate-current plant for the station at Rugby School. With some of these, and with the contracts previously secured for Corporation stations at Worcester and Hanley, considerable progress has been made; while the supply of plant for stations at Prescot, Windermere, and Killarney, and at several other places mentioned above, has been completed. The Brush Company's contracts for exhibition lighting have included this year the supply of the whole of the electrical plant at the Horticultural Exhibition, Earl's Court; and amongst the most important orders for isolated sub-stations in hand may be mentioned the lighting of Arundel Castle, the seat of his Grace the Duke of Norfolk; the residence of Sir Arthur Hayter, Southhill Park, Bracknell; Battenhall Mount, Worcester, belonging to the Hon. Percy Allsopp; High Trees Mansion, Redhill, belonging to M. Marcus, Esq.; and the supply of arc plant on a large scale for the important installation at the Midland Railway Company's station at Leicester. The installation work on shipboard completed by the Brush Company has comprised electrical plant for two vessels belonging to the Pacific Steam Navigation Company; two cruisers for the Argentine Government; extensions to the plant of the steam-yacht "St. George," etc. With regard to the internal organisation of the company, the special facilities possessed by the company in their woodworking and foundry departments at Loughborough have enabled them to contract for the exclusive manufacture of the lifts and hydraulic machinery to the orders of the Otis Elevator Company, an off-shoot of the American Otis Elevator Company, and it is anticipated that this will be an important branch of the Brush Company's manufactures in the future. Having perfected a system of alternate-current distribution, the company have been giving attention to the further development of their continuous-current plant. With this in view they have acquired the sole rights for manufacture in the United Kingdom of the Brush-Desroziers dynamo, a machine which has become a deserved favourite in the central stations on the Continent. They have also begun to manufacture several classes of two-pole dynamos of high efficiency and moderate price, which are finding many buyers. To all these types, as well as to their well-known Mordey-Victoria alternator, the company attach direct engines of their own special make. This does not, of course, preclude the supply of belt or rope drives where these are desirable, but is undertaken in order to meet the growing demand in central stations for direct driving. Important improvements have been made in the company's transformers, alternate-current arc lamps and lamp-posts, accompanied by substantial reductions in price, and, at the same time, particular prominence is being given to the supply of plain fittings, switches, and lampholders, which will shortly be on the market at most favourable figures. The expiration of the Edison patent in November removed an obstacle which had for years barred the field of incandescent lamp manufacture from general exploitation in this country. The Brush Company made extensive preparations to resume their former position in this branch of the electrical industry, relying on their name as a guarantee for first rate material and high-class workmanship, and feeling confident that the reappearance of their lamp would be welcomed on the market, where the Edison lamp had so long been in sole possession. They have been gratified by the ready and widespread sale with which the Brush incandescent lamps have met, and are looking forward to a steady and still larger demand than even the initial rush has brought upon Mr. Alwyn, of 53, Queen Victoria-street, E.C., in whose hands the whole of the sales in Britain has been placed. In its other departments also the company continue to be occupied fully with large and remunerative orders to an extent that taxes their resources to the utmost, notwithstanding the enlargement of their works and the increase of their staff.

DORMAN AND SMITH.—Although this firm have only occupied their new works in Salford for less than two years, they have already found it necessary to make extensions in several departments. Their manufactures, passing as they invariably do through the hands of large and small contracting firms

Digitized by Google

before coming into the hands of the actual consumer, can hardly be analysed in a public announcement. Suffice it to say that their works have been kept fully employed throughout the year, and often on overtime. The leading firms have, as heretofore, demanded an enormous number of accessories, and a noticeable feature of the year is the fact that the thousand and one smaller contractors having now been in business for a sufficient length of time to learn the dangers attending the use of shoddy apparatus, are now compelled to use more substantial material. Their export trade, particularly with our colonies, has increased wonderfully in the last two years. Plenty of work also looms in the distance to keep all their machinery fully going during the new year.

LITHANODE AND GENERAL ELECTRIC COMPANY, LIMITED.—The year 1893 has been an exceedingly busy and progressive one for the Lithanode and General Electric Company, and they report a series of very successful operations. A very large number of portable hand-lamps and other small batteries have been disposed of, and, judging from the repeat orders which have been received for them in almost all cases, they have given entire satisfaction. During the past year many improvements have been made in the manufacture of lithanode, and it is thought that little can be done in the way of further improvements. Good lithanode of very high capacity and great mechanical strength can be made in 24 hours, whereas by the processes employed two or three years ago, the then inferior active material required from two to three weeks to produce. The improvements made have all tended to reduce the cost of production, and the material as now made enables the company to compete commercially in point of price with any other manufacturers. The Lithanode Company report that the names of most of the electrical firms of good standing in this country have been placed upon their books, and many substantial orders from the Continent, America, Australia, and South Africa have been successfully carried through. During the year there has been quite a large demand for lithanode batteries from medical men, and portable lithanode hand-lamps and other batteries for lighting purposes, and also batteries for medical cautery, have been in great demand. Many of the London and also provincial doctors are now using batteries supplied by the Lithanode Company. At the Admiralty, War Office, Science and Art Department, and other Government establishments, lithanode portable batteries are in great favour. The company have given much attention to batteries for vehicle lighting, and as an example of the successful illumination of vehicles may be cited the new Great Northern Railway omnibuses, which are said to be the most perfectly lighted vehicles to be seen in London. The whole of the lamps in these omnibuses are worked by lithanode batteries. There seems to be some misapprehension abroad with reference to the capabilities of lithanode accumulators, and it is generally supposed that this active material is only useful for cells of small dimensions and low capacity. This is an entire fallacy, for within the last 12 months many hundreds of tons of large lithanode cells have been sold; among these being a 220-cell battery for central-station work. Each cell in this particular battery has a useful current capacity of 650 ampere-hours, and is capable of being discharged up to as high a rate as 300 amperes. A large business has been done in the replacement of other makers' positive plates by the company's improved lithanode plates. The result of this combination has in all cases proved entirely satisfactory, and many hundreds of cells of various capacities have been treated in this way. The Lithanode Company's works are now fully equipped for supplying at short notice cells of the following capacities:

Capacity of cells.	Use of cells.
0·5 ampere-hours	Testing, medical, and theatrical purposes.
1·0 ,, ,,	
3·0 ,, ,,	Hand lamps.
5·0 ,, ,,	
6·0 ,, ,,	
8·0 ,, ,,	Portable accumulators for domestic lighting, broughams, tramcars, omnibuses, etc.

The company have not confined their operations to the manufacture of accumulators only, but, in addition to an extensive business in these goods, have carried out during the past year several important electric light installations. The Gresley Brewery, at Gresley, near Burton-on-Trent, has been entirely lighted by this company. This installation, which included dynamos, batteries, switch and distributing boards, instruments, etc., and between 200 and 300 lamps, possesses several novel features, and is an example of the economical utilisation of spare motive power by the aid of electrical storage. A 110-volt lithanode battery, with switchboard and all the necessary accessories, has recently been added to the electric light installation at the Tadcaster Brewery. The company are now engaged in putting down a large and complete electric lighting plant in the Cheltenham Brewery, the adjoining Fleece Hotel, and a moderate-sized private house. For this somewhat unique installation, which partakes somewhat of the character of a small supply station, perhaps the largest set of storage batteries ever put in a private installation is being employed. The batteries are for a 100-volt circuit, and will be capable of actuating between 500 and 600 lamps for a period of fully 10 hours when once charged. The installation will be in duplicate, there being two sets of accumulators and two dynamos, the switchboard being arranged so that either dynamo may run the lamps direct, or may charge one or both sets of accumulators. By this means the generating electrical plant may be arranged to suit the load of the engine, and as the installation can be run from either set of accumulators either separately or conjointly, it is thought that there will not be the slightest possibility of a complete breakdown. In addition to the work already enumerated, the company have carried out extensive alterations to the main switchboard of the General Post Office, London, and have also carried out some work in other important Government establishments. Electrical lighting for stage purposes has occupied a somewhat important position in the company's operations, and many electrical novelties have been carried out at the Alhambra Theatre, the Comedy Theatre, at the Crystal Palace, and at the New Olympic. The portable batteries now in use at Drury-lane Theatre have been supplied by this company, and perhaps the most extensive temporary installation of the electric light on the stage is now being carried through by this company for Mr. Oscar Barrett at the Lyceum Theatre. For scientific and testing purposes, lithanode batteries have been very successful, and many large testing batteries have been installed in several of the most important

Digitized by Google

laboratories in this country. Among these may be cited a 100-cell 12 ampere-hour battery for Lord Kelvin's laboratory in Glasgow, and similar testing batteries have been supplied to the University College Laboratory, London; Board of Trade Electrical Department, London; the Brush Electrical Engineering Company, Loughborough; and the Brighton Corporation electricity works.

C. A. PARSONS AND CO. have during the past year supplied turbine engines to the Newcastle and District Electric Lighting Company, the Cambridge Electric Supply Company, and the Scarborough Electric Supply Company, showing an aggregate of 1,400 h.p., as well as numerous smaller plants of the steam-turbine class, and ordinary plants for ship, mill, and private house lighting, a total of about 2,000 h.p. They have in hand steam-turbine motors of an aggregate of over 3,000 h.p., including a 250-h.p. steam-turbine alternator for the Portsmouth Corporation. They have in hand as well contracts for search-light reflectors and other electrical specialities.

PATERSON AND COOPER.—This firm report that the past year has been one of unparalleled depression in the electrical engineering trade, but that they have, however, been fairly well employed. The following vessels have been fitted with complete installations: ss. "Matin," for Messrs. Mudie and Sons, Dundee; "Princess Beatrice," for Messrs. Langlands and Co., Liverpool; "Laurentian," for the Allan line; "Empress," for R. Carson, Esq., Hull; "Zaire," for F. T. Laws, Esq., Liverpool; "Noir-el-Bahr," for Messrs. Gourlay Bros., Dundee. Direct-driving sets for the ss. "Premier," of the Canadian Pacific Company, and for other vessels have been supplied. Complete search-light apparatus, with direct-driving set, has been supplied for a revenue steamer. The principal installations carried out have been the private residence of H. W. Buddicom, Esq., Penbedw, North Wales, comprising a direct-driving set, 108 L-31 accumulators, fitting of mansion with lights and bells, and several motors for sawing, pumping, churning, etc.; the private residence of M. G. Thorburn, Esq., Glenormiston, Peebles, comprising turbine and dynamo, cells, and fitting lights in mansion; Jury's Hotel, Dublin, 300 16-c.p. lights, with direct-driving set running at 175 revolutions per minute; the private residence of W. Prettey, Esq., Ipswich; Messrs. Flower's corn-mill at Ramsey; the Ocean Ironworks, Manchester; the Town Hall and Royal Hotel, Derby; the Great Northern Hotel, King's Cross; the Queen's Hall, Portland-place, etc. In small work, Admiralty contracts of considerable size have been executed. During the past year Messrs. Paterson and Cooper introduced their new patent five-ampere lamp, which has met with a very favourable reception; they have also brought out improved electrical measuring instruments, which have met with approbation, and have taken up the agency for Messrs. Richard Frère's electrical measuring and recording instruments. Of works at present in hand the most important are: Messrs. Buchanan and Sons' Works, Liverpool, 22 arc lights and dynamo; the private residence of R. K. Micklethwaite, Esq., Ardsley House, Barnsley; and the Municipal Buildings, Ealing.

SWINBURNE AND CO., LIMITED, report themselves as having been very busy throughout the year just completed, during the latter half of which they have been working overtime almost continuously. Amongst the most important contracts completed by them during this time is that for a set of motor-alternators for the Woolwich Electric Supply Company, to be worked in conjunction with the Pritchett secondary battery. Turning to other things, their small and large power alternators have met with great success, and the demand for these and for their ordinary direct-current machines shows signs of rapid increase. The same remarks apply to their new closed-circuit transformer, which has proved a great success whenever it has been tried, and is bound to have a large sale in the future on account of its many good qualities combined with very moderate price. In their instrument department they have devoted themselves chiefly to the perfection of the Swinburne electrostatic voltmeter, which is now gradually taking its place as the recognised alternating-current voltmeter on central-station switchboards. Their installation department has also made considerable progress during the year. They report having a large number of orders on hand in all departments, the outlook for the coming year being very promising.

WATERHOUSE ELECTRICAL MANUFACTURING COMPANY.—This firm state that, taking into account the delay which must necessarily be incurred in starting a new business, there is every prospect of the Waterhouse arc lamp being most successful. They are turning out lamps at the rate of 20 a week, and have many orders on hand. It is stated that soon the Waterhouse meter will be placed on the market, and it is thought by the company that it will be the meter of the future.

WILLANS AND ROBINSON state that the horse-power of the engines ordered from them during the year 1893 amounted to 18,950. This is a large increase on past years, and as it may be interesting by way of illustrating the growth of the business, and the increasing recognition of the merits of the Willans central-valve high-speed engine, to note the progress that has been made, we may say that the total orders booked in 1892 amounted to 14,300 h.p., and those in 1891 to 11,100 h.p. The engines ordered in 1893 vary in size from 40 h.p. to 570 h.p., and the majority of them are for direct coupling to dynamos. It is evident, however, that the Willans engine is coming into favour as a motor for supplying power as well as for lighting purposes, for recently orders have been given for several mill engines — among others, for one of 570 h.p. for a flax mill in Belfast, and another of 540 h.p. for a flour mill in Germany. Among the new electric light stations for which orders have been received during the past year may be mentioned the towns of Nottingham (650 h.p.), Aberdeen (320 h.p.), Lancaster (395 h.p.), Hampstead (860 h.p.), Warrington (270 h.p.), and Dewsbury (400 h.p.), and the following companies: Southampton Docks (light and power, 240 h.p.), Lancashire and Yorkshire Railway (300 h.p.), Royal Albert Dock (600 h.p.), Birmingham Grand Hotel (180 h.p.), and Holborn Restaurant (400 h.p.). The repeat orders during the past year from various companies who use these engines amount to 7,876—the principal ones being the Liverpool Electric Supply Company, (1,920 h.p.), the Westminster Electric Supply Corporation (1,160 h.p.), Brighton Corporation (720 h.p.), General Post Office (394 h.p), Birmingham Electric Supply Company (200 h.p.), St. James and Pall Mall Electric Light Company (550 h.p.), Bradford Corporation (400 h.p.), St. Pancras Vestry (400 h.p.), Bristol lighting (720 h.p.), Chelsea Electric Light Company (205 h.p.), Glasgow Corporation (720 h.p.). Many stations have, of course, been erected and started

Digitized by Google

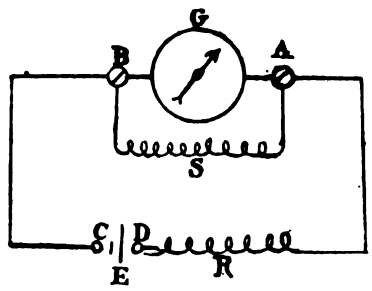
during the past year, the engines for which were ordered previously, such as Bristol (1,440 h.p.), Glasgow (1,210 h.p.), London and North-Western Railway (384 h.p.), City Lighting Company, Bankside station (1,440 h.p.), Dundee lighting (660 h.p.), Norwich lighting (300 h.p.). These figures are independent of the repeat orders mentioned above. At the Chicago Exhibition the company had two engines, one of 360 h.p. and the other of 165 h.p. These were driving shafting in the British section of the Machinery Hall, and we understand that for two months or more, owing to an accident to another engine in the section, they drove the whole of the shafting in it. Several other Willans engines were shown, one a 300-h.p. set coupled to a Siemens dynamo which was used for driving search-lights, and several smaller ones made by the M. C. Bullock Manufacturing Company, of Chicago, the American licensees. The total horse-power of the Willans central-valve engines now in use or on order amounts to 76,440.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

SHUNTS.

SIR, — Your correspondent "H. L." has in his last communication raised so many points on the above subject, that it is rather hard to answer him effectually without adding confusion to the maze of difficulties out of which he wishes to be led. His chief stumbling-block seems to be the "text-book" statement, that a shunt applied to a circuit diverts portion of the current flowing through that circuit. Perhaps the best method of helping him is to first examine clearly the effect of applying a shunt to, say, a galvanometer.



Take the case represented in this diagram. When the shunt is applied, the resistance between A and B is reduced to $\frac{G\,S}{G+S}$, and as this reduction affects the total resistance of the circuit, the E.M.F. acting between A and B may be also affected. I have said "may be," because there are cases in which it "may not be." The E.M.F. between A and B, which we shall call E′ to differentiate it from the E.M.F., E, at the poles of the battery, is when the galvanometer is unshunted.

$$E' = \frac{E}{R+G} \times \frac{G}{1} = \frac{E\,G}{R+G} \quad . \quad . \quad . \quad (1)$$

When the shunt is applied,

$$E' = \frac{E}{R + \frac{G\,S}{G+S}} \times \frac{G\,S}{G+S} = \frac{E\,G\,S}{S\,(R+G) + G\,R} \quad (2)$$

Now "H L" will easily see that there are cases in which equations (1) and (2) are equal—*i.e.*, when R equals 0; and also cases in which they are approximately equal—*i.e.*, when R is negligible in comparison with G. In such cases the E.M.F. at A and B will be practically unaffected, and the current will be the same in the galvanometer whether it is shunted or not.

To put the matter more exactly, the difference between equations (1) and (2), which equals

$$\frac{-E\,G^2\,R}{\{S\,(R+G) + G\,R\}\,\{G+R\}},$$

is the amount by which the E.M.F. is reduced on the addition of the shunt.

The currents in the galvanometer and shunt may be respectively found by dividing equation (2) by their respective resistances.

Now, it is usual in the "text-books" to say that a shunt applied to a galvanometer reduces the current $\frac{S}{G+S}$ times, and the student takes it that this means $\frac{S}{G+S}$ times the current flowing without the shunt. How far this is true can easily be shown.

The current in galvanometer unshunted is $\frac{E}{G+R}$, and if the shunt reduces this $\frac{S}{G+S}$ times, then the current when shunted should be

$$= \frac{E}{G+R} \times \frac{S}{G+S} = \frac{E\,S}{G^2 + G\,R + S\,(R+G)} \quad . \quad (3)$$

but we have shown in equation (2) that it really is

$$\frac{E\,S}{G\,R + S\,(R+G)} \quad . \quad . \quad . \quad . \quad . \quad (4)$$

It is evident that these equations can never be equal if G has any value, and can be only approximately equal if G is small in comparison with R. If G has not a negligible value, and it is absolutely necessary to reduce the current in it $\frac{S}{G+S}$ times, then the obvious remedy is to add a compensating resistance as well as a shunt. The value of the compensating resistance is $G - \frac{G\,S}{G+S} = \frac{G^2}{G+S}$, and I think "H. L." will see that this allows the E.M.F. between A and B to be varied to the desired extent, so that $\frac{E'}{G}$ will be $\frac{E'\,S}{G+S}$ times reduced on the application of the shunt.

No doubt "H. L." has taken the approximately true statement of the text-books as being absolutely correct, and finding those cases in which it is glaringly out has started "cussing 'em." But let the text-book authors answer for themselves.

Hoping the above remarks may be serviceable to "H. L."—
Yours, etc.,
J. SINNOTT.

Haverfordwest.

N.B.—In "H. L.'s" enquiry, under "equal deflection" paragraph, the E is invariable in the formulæ. It is the E.M.F. of battery taken at its poles.

HIGH-SPEED ELECTRIC RAILWAYS.

SIR,—In reference to the article by Mr. F. B. Lea in last Friday's paper, I would like to point out that there is no real disparity between the values found for the air resistance by Dr. Hopkinson and Mr. O. T. Crosby. The difference is due to the "skin friction" of the air on a long train. Though this is relatively a small quantity per square foot, we have in the case of a train with the given dimensions an area of 7,900 square feet exposed to its action. I have not the exact values to hand, but I know that this forms a large part of the resistance of trains, and it varies with the square of the velocity.—Yours, etc.,

CHAS. E. WOLFF.

Brook Cottage, Ockbrook, near Derby, January 6, 1894.

Rome.—It is reported that the cable supplying the Via Nazionale and the Corsa at Rome with the electric light was cut on Sunday.

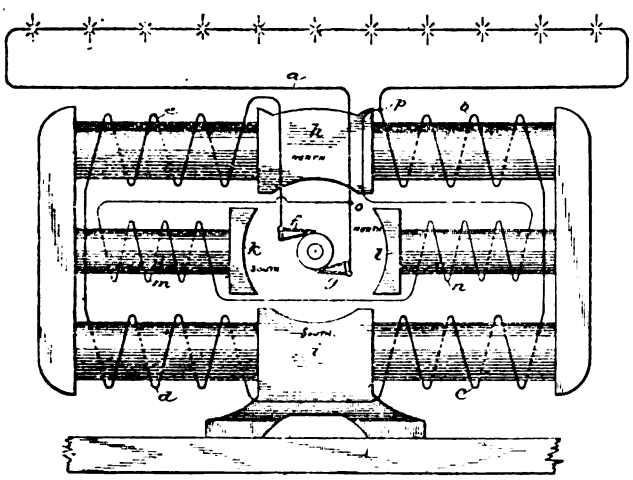
THE SCRIBNER CONSTANT-CURRENT ARC DYNAMO.

Mr. Charles E. Scribner, of the Western Electric Company, has recently devised an interesting method of avoiding sparking at the brushes of dynamos due to sudden changes of load, and described in a patent just issued. In this system the current built up in each coil while it is short-circuited is of the same direction and strength as that in the circuit of the current-producing coils into which it is introduced when the short-circuit is removed; that is to say, while each coil is short-circuited its current goes to zero, and then is built up to a certain extent, and by controlling this building up of the current in such manner as to make the current built up equal to that in the circuit of the coils into which it is introduced, objectionable sparking is avoided.



Scribner Constant-Current Arc Dynamo.

By reference to the accompanying diagram it will be seen that the main circuit, *a*, including the lamps, may be traced through the coils, *b c d e*, of the field magnets of the short-circuited coils, and thence through the pairs of brushes, *f g*. The poles, *h i*, are thus magnetised by these coils. In addition to these field magnets of the short-circuited coils there is provided the pair of magnets, *k l*, with the coils, *m n*; these coils are included in a shunt circuit between the points *o p*, which are connected with different sides of an arc light circuit. The magnets, *k l*, which have their coils included in the shunt between the points *o p* on different sides of the lamps are so placed with reference to the brushes and the revolving armature as to produce a field whose lines of force are cut by the current-producing coils. It is evident that as the number of lamps in the circuit is increased more current will be sent through the coils, *m n*; in other words, the increase of work to be done increases the field of the coils which produce the current to do the work, and *vice versâ*.

The poles, *h i*, are in position to produce a field which is cut by the short-circuited coils, and the windings, *b c d e*, are such that the circuit built up in the short-circuited coils is equal to the current in the circuit of the current-producing coils into which the short-circuited coils are introduced.

According to Mr. Scribner, between 50,000 and 60,000 ampere-turns of No. 16 wire upon poles which determine the E.M.F. of a dynamo of 1,000 to 1,200 volts maximum capacity will give the desired regulation. The size of the field should be so proportioned that this number of turns will have a resistance of from 500 to 600 ohms. The main fields may be varied to give the proper current in the short-circuited coil upon first building the dynamo, the number of ampere-turns necessary depending, of course, upon the character of the iron used and the shape of the pole-pieces of the main field cores. If the dynamo at 1,000 volts with the brushes clean gives a current higher than is desired, a reduction in the number of ampere-turns upon the magnets whose poles, *h i*, are placed over the short-circuited coils, can be made to bring the current to the desired strength.—*Electrical Engineer* (New York).

WAKEFIELD ELECTRIC LIGHTING.

The following is the report of Mr. Robert Hammond, M.I.E.E., upon the proposed establishment of municipal electricity works in this city.

1. Following your instructions I have pleasure in reporting to you upon the proposed establishment of municipal electricity works in your city.

2. I understand that since my interview with your General Purposes Committee, your Town Council have carried into effect their determination to apply for a provisional order under the Electric Lighting Acts, 1882-1888, and have chosen a compulsory area situated in the centre of the city.

3. I beg to lay before you the reasons why, in my opinion, it would be prudent on the part of your Corporation to carry out the provisions of the order and to lay down electricity supply works.

4. "Electricity supply" has completely emerged from the experimental stage, and is now firmly established as a sound and remunerative business, the works which are at present in operation absorbing a capital of over 4½ millions.

5. To give you a clear idea of the present position of electricity supply in the United Kingdom, I set forth a tabulated statement of the electricity works at present in operation, under statutory powers, the capital invested being set out and a discrimination made between those works situated where the gasworks belong to the corporation and where they belong to a company. This table is not confined to works belonging to local authorities, because the amount of capital already invested in the industry by private enterprise, as indicating the opinion of capitalists, has a very important bearing on the question of the soundness of the electricity supply industry.

TABLE A.—Electricity Works (holding statutory powers) in Actual Operation in the United Kingdom. Statement of Capital Invested.

Date of starting supply.	Name of place.	Supply by companies.		Supply by local authorities.	
		Where gasworks owned by a company.	Where gasworks owned by local authority.	Gasworks owned by a company.	Gasworks owned by local authority.

	Totals...	£4,017,060	£126,000	£397,200	£498,300

Digitized by Google

6. It will be seen that the total capital invested at the present time in electricity supply works operating under statutory powers and actually in operation is £5,038,560, which is contributed as follows:

Owned by.	Capital invested.
Companies	£4,143,060
Local authorities	895,500
	£5,038,560

7. In only two cases where the gasworks belong to the corporation—*i.e.*, Birmingham and Leeds—have the local authorities allowed a provisional order to go into the hands of a company.

8. In addition to the electricity works already in operation, there are 12 new works for which contracts have been given out, and the amount of capital involved therein may be tabulated as follows:

TABLE B.—Electricity Works in Course of Construction in the United Kingdom.

Name of place.	Supply by companies.		Supply by local authorities.	
	Where gasworks owned by a company.	Where gasworks owned by local authority.	Gasworks owned by a company.	Gasworks owned by local authority.
	£	£	£	£
Burton-on-Trent	—	—	—	25,000
Cardiff	—	—	32,500	—
Dewsbury	—	—	—	25,000
Ealing	—	—	25,000	—
Hampstead	—	—	25,000	—
Lancaster	—	—	—	25,000
Londonderry	—	—	15,000	—
Leicester	—	—	—	50,000
Oldham	—	—	—	27,000
Portsmouth	—	—	56,385	—
Richmond	20,000	—	—	—
Worcester	—	—	39,109	—
Totals	£20,000	—	£192,994	£152,000

9. It will be seen that in the case of these new works, none are being erected by companies in localities where the gasworks belong to the corporation, and that the amount of new work which companies have in hand bears only an insignificant proportion—5·79 per cent.—to that of local authorities:

Owned by.	Capital invested.
Companies	£20,000
Local authorities	344,994
Total	£364,994

which sums added to those given above (Table A) result as follows: Tables A and B (combined).

Owned by.	Capital invested.
Companies	£4,163,060
Local authorities	1,240,494
Total	£5,403,554

10. In addition, however, to the capital involved in works in actual operation and in course of construction, large sums have been voted by town councils for the laying down of electricity works, and specifications are being considered with a view of contracts being given out. These sums may be summarised as follows:

TABLE C.—Electricity Works Decided Upon (but contracts not yet given out) in the United Kingdom.

Supply by companies.		Supply by local authorities.	
Where gasworks owned by a company.	Where gasworks owned by local authority.	Where gasworks owned by a company.	Where gasworks owned by local authority.
£	£	£	£
35,000	Nil.	502,972	373,000

Again, note the great display in value—3·9 per cent.—of the new works decided upon by companies and by local authorities:

Owned by.	Capital invested.
Companies	£35,000
Local authorities	875,972
Total	£910,972

Reaching the grand total of Tables A, B, and C (combined).

Owned by.	Capital invested.
Companies	£4,198,060
Local authorities	2,116,466
Total	£6,314,526

11. In addition to the above there are some 43 places in which electricity works are projected, but in which no final decision has been come to. These works, if carried out, would involve a further expenditure of over £750,000.

12. The above figures are significant. They indicate: (1) That there is a consensus of opinion in favour of the establishment of electricity supply works; (2) that though the bulk of the pioneer work has been done by private enterprise, the newer works are almost all being undertaken by local authorities; (3) that with only two exceptions has any local authority owning the gasworks sanctioned the granting of statutory powers to a company.

13. It is a matter of importance in the cases where provisional orders have been sanctioned by corporations owning their gasworks, to consider the terms of purchase that have been arranged. The Leeds terms are as follows: The Leeds Corporation has the right of taking over the works and business of the company: (A) At any time prior to July, 1901, by the issue to the company of such an amount of Leeds Corporation stock as will produce by the interest or dividends thereon an annuity of 5 per cent. per annum upon the sum expended by the company upon the undertaking and chargeable to capital account, and also the payment to the company of a sum equal to the aggregate amount of a dividend of 5 per cent. per annum on the said capital expenditure, less the aggregate amounts of the dividends declared by the company up to the date of purchase. (B) At any time from July, 1901, to July, 1912, by the issue to the company of such an amount of Leeds Corporation stock as will produce by the interest or dividends thereon an annuity of 5 per cent. per annum upon the capital account of the company. N.B.—For instance, if at the date of such purchase the capital so expended were £50,000, the company would receive sufficient Corporation stock to produce £2,500 per annum, the market value of which is now about £80,000. (C) At any time between July, 1912, and July, 1922, either on the above-named terms (B) or upon the Corporation paying the company the then value of the undertaking in accordance with Section 2 of the Electric Lighting Act, 1888, together with such additional sum as may be determined by arbitration to be the value of the goodwill of the undertaking. (D) After the expiration of July, 1922, or at the end of every subsequent period of seven years, either on the terms of (B) or upon the Corporation paying the company the then value of the undertaking, in accordance with Section 2 of the Electric Lighting Act, 1888; but the option of purchase on the terms of (B) ceases in 1933.

14. From the above it will be seen that where a Corporation permits a company to obtain a provisional order, the Corporation has only the right of the acquisition of the undertaking, prior to the expiry of the time allotted by Parliament, under terms extremely favourable to the company.

15. Turning to the question of the financial results of the works already in operation, it would, of course, be idle to expect that they should show, in the very early days of their working, the same results as may be expected from concerns long established and with settled businesses. The following table, however, shows the margins, on the right side, between costs of working and revenue as exemplified by the 1892 balance-sheets of electricity works:

Name of works.	Margin between total costs and revenue.	On a capital of	Per cent. of margin to capital.
	£	£	
Birmingham	3,488	70,000	4·98
Bradford	1,476	34,243	4·31
Charing Cross	10,247	200,900	5·10
Chelsea	4,319	80,585	5·36
Eastbourne	1,746	37,119	4·70

Brighton	2,229	52,563	4·24
	£110,682	£2,177,963	5·08 % (average)

16. It will be noticed that in almost all the above cases there is sufficient margin between the costs of production and the revenue to provide for the annual sinking fund required to repay the electric light loan, if the supply were in the hands of the local authority.

17. The General Purposes Committee of the Birmingham Town Council have, however, just reported "that at present at all events, the profits made from the supply of electricity are inconsiderable"; but they overlook the highly-important fact that the bulk of the works in operation are only in the initial stage, and as they develop, and the demand increases, they will work at much cheaper costs, and show much more substantial margins between costs and revenue.

18. The active increase in the demand, however, will largely depend upon the possibility of being able to directly compete with gas in price, for the greater number of householders, as a rule, are compelled by stern financial necessity to give the preference to the less desirable article on account of its cheaper price.

19. At present electricity is being supplied in various towns at

Digitized by Google

prices which compare with gas at from 2s. 6d. to 4s. per 1,000ft., and at Wakefield if 6d. per unit be fixed upon as the charge, it will compete with gas at 3s., if 7d. per unit 3s 6d., per 1,000ft.

20. It must be remembered, however, that these prices are on the basis of a limited production, while they are compared with gas produced on a large scale. It is fair to assume that when electrical energy is produced on the same scale as gas it will directly compete with it in price.

21. One important feature in this connection is the series of improvements which are certain to occur in the incandescent lamp, on a par with those that have from time to time taken place in gas-burners. When the incandescent lamp was first invented it required, with a life of about 1,000 hours, according to the size of lamp, five to six watts for one candle of light. Now it requires three watts to 4½ watts for one candle of light. The manufacture of incandescent lamps in the country is now thrown open, and the German makers are offering short-lived lamps to consume only 2½ watts per candle. When, by various improvements in the filament, less electrical energy is required to produce each candle of light, without a curtailment of the life of the lamp, the comparison between the cost of electrical energy and gas as illuminants will become more and more favourable to electricity. If for the same amount of light a consumer should only use 100 units, at 6d. per unit, where he now uses 200, electricity to him will practically only cost half its present price.

22. Again, in the production of electricity at present there are no by-products, but there is a large margin for the utilisation of the electrical plant for purposes other than lighting. The work of generating electricity for lighting is only equivalent to about two and a half hours' use of the plant daily all the year round. If a full use of the plant during the remaining 21½ hours of the 24 were discovered, it would be possible to make a profit out of selling electricity at even less than 2d. per unit. This would correspond, say, to less than 1s. per 1,000ft. for gas. The advantages which gas derives from by-products will probably accrue to electricity in time through by-uses of the plant. However small, therefore, be the margin of profit at the beginning, there is a probability of large profits being made by degrees, without adding to or altering the plant.

23. To sum up, it may be contended that the business of electricity supply is based at the present stage on sound commercial lines, and that its future is all in the direction of cheaper costs.

24. The question, then, for the city of Wakefield to decide is whether it should keep the business in its own hands or sanction its transference to a company. If the latter course be adopted the Electric Lighting Acts provide for a 42 years' tenure by the company, and even if an arrangement be made for an earlier purchase, it is manifest that the Corporation will be called upon to pay a pretty heavy bonus, as already instanced by me in the case of Leeds.

25. It is, however, in any case manifest that the ratepayers will be better off if supplied by the Corporation than by a company, because the price charged by a company must cover the cost of administration by directors and also a provision of a good dividend to shareholders, whereas in the case of supply by the Corporation there will be no directors to pay and no fat dividends to provide. The local authority will, I presume, be able to borrow the capital necessary at 3 per cent., a rate that would, of course, not satisfy the shareholders in a company.

26. Again, if the Corporation were to sanction the transfer of its provisional order to a company, the first step of the company would be to select a compulsory area, limited in extent, but comprising the choicest portion of the town, from the electric lighting point of view. Ratepayers inside this area would be able, by the use of the electric light, to make their places of business more attractive, to the detriment probably of the ratepayers outside, who cannot demand a supply for two years, and can then only obtain it under onerous conditions of guarantee, etc.

27. In the hands of a company the growth of the undertaking must necessarily be slow. The shareholders, believing in quick returns, insist upon immediate and good dividends as the precursor to any enlargement of the capital account. The business is therefore often cramped for capital from the beginning, and the unfortunate ratepayers in the "outside area" are left in the lurch.

28. Your Corporation could afford to take wider views. If the business be in itself sound, your aim will be to develop it on an extended basis as rapidly as possible. You could afford to make "capital extensions" without waiting for a 5 per cent. or 6 per cent. return upon the work in the compulsory area; your principal aim being, with due regard to permanent profitable results, to extend the benefit of electricity supply throughout the whole of the district under your control.

29. Again, your Corporation has a strong interest in the advancement of any scheme which tends to improve the sanitary conditions of your city, and though the advantages of the electric light are now almost generally acknowledged, I venture to summarise the conditions which attach to the perfect light, and which are fulfilled by the incandescent light—*i.e.*, it must (1) not feed on the air; (2) add no noxious fumes to the air; (3) give off no appreciable heat; (4) be free from danger of causing fire; (5) not injure a tradesman's stock; (6) do no damage to ceilings, furniture, etc.; (7) not injure the sight; (8) be quite reliable; (9) not escape; (10) be absolutely free from danger to life or limb; (11) be convenient, capable of being measured and economised, and arranged artistically.

30. I may mention another advantage attaching to the supply being in the hands of the corporation—viz., that the corporation is itself a good customer in the direction of public lighting. The greatest inconvenience in electricity supply is that arising from the fact that the demand ceases almost entirely at bedtime, and it greatly assists economical working if the load can be continued far into the night, and the public lighting to a certain extent provides for a continuance of the load.

31. I am, in the above remarks, taking for granted that the Corporation will desire, certainly as the works develop, to adopt electric lighting in the public streets. The incandescent light, which is used in the houses, is not suitable for street-lighting, and I should recommend the adoption of the arc light. An arc light, however, gives a very much more brilliant light than the best gas-lights, and the result of introducing the arc light would therefore be to give a very much more brilliant illumination to the streets, resulting in an increased security both to persons and property, it being the experience of cities where the arc lighting has been introduced that crime has been reduced and the number of accidents minimised.

32. In the case of adopting arc lighting extensively, it is well to have the lamps arranged upon two circuits, so that each alternate lamp can be turned out, say, at 11 o'clock in the evening, the extinguishing being done by the movement of a switch at the central station, without involving the cost of a lamp-lighter. Street-lighting is, in my opinion, an extremely valuable accompaniment to incandescent lighting, as the streets in which the electric lights are placed are of course far better illuminated and lead to the better illumination of neighbouring premises. They also act as an attraction to people living in neighbouring places, and may be relied upon to generally increase the business of the place.

Selection of Site.

33. The most important point to be first considered is that of site. The nearer the generating station is to the centre of supply the better, and I have carefully considered the advisability of adopting the site owned by your Corporation at the top of Kirkgate.

34. As it is possible, when dealing with the problem of electricity supply, to lay down the initial works on a comparatively small scale and to gradually add plant, unit by unit, as the load increases, it is evident that though a small site may be suitable at the start, it is of vital consequence to provide good room for extensions, as if the undertaking proved a great success and the enlargement of the works could not be effected on the site originally chosen, it would be necessary to lay down second works—manifestly a very extravagant method of proceeding.

35. The Kirkgate site is very limited in extent, and I do not therefore recommend that the works should be erected on it, or, indeed, on any other site where ample room for extensions is not available. I have visited the sites which lie at the outskirts of the city, and I find that both the site at the proposed sewage works and the site at the sanitary depôt are suitable. I have based my estimate upon the establishment of the works upon the sewage site.

System of Supply and Estimate of Cost.

36. The next point to be considered is that of system. There is not a wide difference between the various systems of generation of electricity, but there are many systems of distribution of electrical energy for house-to-house lighting by means of incandescent lamps. The filaments within these lamps are made to stand only low pressure, and whatever system of generation or distribution may be adopted, the electricity must finally be delivered to the lamps at low pressure—*i.e.*, low tension. Distribution at low tension throughout, however, involves the use of a large quantity of electricity, since the electrical energy required for lighting is the product of pressure and quantity. For instance, 1,000 lamps, requiring each 35 watts of electrical energy, use a total of 35,000 watts, which may be brought from the generating works in the form of

Pressure.		Quantity.	
2,000 volts	.....	17·5	amperes
1,000 ,,	.....	35	,,
500 ,,	.....	70	,,
300 ,,	.....	116·6	,,
100 ,,	.....	350	,,

The size of the mains is governed by the quantity of electricity to be conveyed and the distance to which it has to be conveyed. It is manifest, therefore, that distribution by means of low tension necessitates much larger mains than distribution by means of high tension, and in scattered areas the length of the mains practically prohibits low-tension distribution.

37. In Wakefield, however, the city covers a compact area, the bulk of the lighting being embraced within a radius of half a mile from a central point. This can very easily be coped with by means of a pressure of 200 volts (three-wire system). In order, however, to keep the size of the main within practicable limits it will be necessary to generate the electricity at high tension and to bring it at high tension to the distributing station in the city, say at Kirkgate Corner or at any other suitable site which may be available. This distributing station would be in charge of an attendant, and from it the electricity would be distributed by means of cables radiating throughout the city.

38. The cost of a 3in. culvert and the cable requisite for bringing sufficient electricity from the sewage site to maintain, say, 6,500 incandescent lamps burning simultaneously would be £1,452, the cable being of section large enough to provide for a loss of electrical energy on route of only 5½ per cent. at full load, the loss dropping down to zero as the load diminishes. The annual monetary value of this loss can be estimated by calculating the total cost of production, and taking this at about £2,000, the 5½ per cent. would work out £110. As, however, the 5½ per cent. loss only occurs at full load and dwindles to nothing at no load, it would be safer to take the average at 1 per cent., or, say, £20. To this must be added the amount of the annual charge involved by

Digitized by Google

the capital outlay. Presuming that the city borrows at 3 per cent. and arranges to pay off the electric lighting loan in 25 years, the annual charge in respect of the above named £1,452 would be £83. 10s.; cost of the electrical energy lost on the route estimated at £20; total, £103. 10s.; which represents the annual cost of the distant site.

39. As a set-off against this annual charge there are many important advantages connected with the distant site: (1) It is of such a size that the city will not be compelled, as many have been, to choose cramped up and unsuitable driving engines; (2) water will be available for condensing, the effluent sewage being probably available; (3) coal will be obtainable at a cheaper rate than if delivery had to be made into the centre of the city; (4) supervision of the borough officials will be facilitated by the proximity of the electricity works to the sewage works.

Size of Works.

40. I have already pointed out that in coping with the problem of electricity supply, the plant can be laid down in instalments to meet the actual requirements of the city. In any case, whatever the size of the plant, it is desirable to divide it into units, as only for about half an hour daily is the full capacity of the plant required. On the other hand, too small a sub-division is undesirable, as small engines do not work so economically as large ones.

41. I recommend that the unit should not be smaller than 150 i.h.p., driving an alternator dealing normally with a maximum load of 75 kilowatts—*i.e.*, capable of lighting 2,500 incandescent lamps all burning at one time, permitting the fixing of about 3,750 lamps on the premises of the consumers.

42. I estimate that the cost of works containing this size unit would be £12,000, which figure covers all engineering charges and a fair margin for contingencies. It includes: (1) Suitable building, to cost with the foundations of the plant, £1,500; (2) Lancashire boilers, with feed-water heaters, and all necessary steam and exhaust pipes; (3) horizontal slow-speed engines; (4) alternators; (5) switchboard; (6) condensing arrangements; (7) 2,100 yards 3in. cast-iron culverts; (8) 8,400 yards of well-insulated high-tension cables (*i.e.*, four cables of 2,100 yards each; this sub-division providing for easy manipulation, testing, and repair, to connect the generating with the distributing station, and of a size capable of carrying the electricity generated by three such plants; (9) plant of distributing station; (10) 2,850 yards of well-insulated triple concentric low-tension distributing mains, with all requisite feeders for three such plants; (11) 10 arc lamps, lamp-posts, and switches.

43. But it must be borne in mind that the costs of working a large plant are, in the main, the same as those incurred in working a small plant, the only additional expenses of working a large plant as compared with a small one being that of the extra coal and the wages of additional engine-drivers and stokers and (with mechanical stokers) up to three units of plant there is hardly any additional wages at all. Unless, therefore, it is of vital importance to minimise the capital expenditure, it is hardly wise to limit the first works to one unit of plant.

44. The cost of two 150-i.h.p. plants with a capacity of 5,000 lights burning at once, and, say, 7,500 lights installed, would be £15,750, including 15 arc lamps, posts, switches, etc., for public lighting, and £2,250 for the buildings, foundations, etc.

45. The cost of three such plants with a capacity of 7,500 lights burning at once or, say, 11,250 lights installed, would be £19,500, including 20 arc lamps, posts, switches, etc., for public lighting, or for letting out to tradesmen, etc., and £3,000 for the buildings, foundations, etc.

46. For economically dealing with the low loads between 11 p.m. and sunset the next day, I recommend the use of a small day load self-contained plant of 50 i.h.p., the cost of which with necessary additions to switchboard would be £650. This sum must therefore be added to each of the foregoing estimates.

47. Summarising the foregoing we have:

(A) Plant for 2,500 lights burning at once or 3,750 installed, costs	£12.000
(B) Plant for 5,000 lights burning at once	15,750
(C) Plant for 7,500 lights burning at once	19,550
(D) Day load plant for 800 lights burning at once	650

Revenue.

48. In order to arrive at a just appreciation of the probable revenue, an estimate must be made of the probable consumption of electricity in the city of Wakefield. This can, of course, only be arrived at by comparison with other places.

49. The following is a statement of the consumption of electricity per lamp fixed which obtains in some of the central electricity works already in operation:

Name of town.	Annual consumption per lamp fixed.
Bradford	18·45
Birmingham	18·09
Brighton	19·51
Bournemouth	18·20
Exeter	19·14
Southampton	22·53
Liverpool	27·49
Northampton	10·94
Leeds (not yet ascertained, the supply having only been started in May last)	—
	154·35
Average of eight places	19·29

To be well within the mark, I think that the revenue may be calculated in Wakefield on the basis of a consumption of 18 units per lamp fixed.

50. The next step must be to determine what percentage of lamps may be fixed in excess of the maximum which the station can produce. In some localities it is found that out of every 100 lamps fixed there are never more than 50 in use at any one time, and in these places it is, of course, quite safe to instal throughout the town just double the number of lamps which the station can produce at any one time. In Wakefield I gather that the bulk of the demand will come from business premises, and under these circumstances it will probably be found that out of every 100 lights fixed 66 will be all on at one time.

51. Having decided that 50 per cent. more lights may be fixed than the maximum capable of being produced at the works, it will be for you to decide to what extent you will provide for reserve plant.

Plans.	Normal.			
	Capacity in horse-power.	Capacity in kilowatts.	Capacity with lights all on at once.	Permitting of fixing 50 % in excess.
A + B	200	100	3,300	4,950
B + D	350	175	5,800	8,700
C + D	500	250	8,300	12,450

If, however, all the above lights were fixed, there would be absolutely no margin of reserve. On the other hand, it must be borne in mind that the time of top load only lasts for about half an hour daily, and the risk involved in running the plant to its full capacity during half an hour daily is only very slight, and as the plant which I have specified is of first-class quality there would be a minimum risk of breakdown, especially as the plants could in an emergency be run with ease fully 20 per cent. beyond their normal capacity.

52. According to the number of plants the following would be the revenue on the basis of the consumption of 18 units per lamp per annum arrived at before.

Plan.	Lamps fixed.	Annual consumption of electrical energy per lamp in B.T.U.	Total annual consumption of electrical energy in B.T.U.	Revenue at 6d. per unit (equal to 3s. per M. for gas).
				£
A + D combined	4,950	18	89,100	2,227
B + D ,,	8,700	18	156,600	3,915
C + D ,,	12,450	18	224,100	5,602

Cost of Working.

53. The staff required for working the station under the various plans would be:

Officer.	Duties.	A and D combined.	B and D combined.	C and D combined.
		Per annum £	Per annum £	Per annum £
Engineer	Complete management of the works	200	200	200
Junior electrician	In charge of switchboard at heavy load	52	52	65
Ditto	In charge at light load	52	52	65
Cleaner	Cleaning the plant, and in charge at lightest load	52	52	52
Engine-drivers	Driving engine at heavy load	91	91	182
Engine-driver	Stoking and running engine at light load	91	91	91
Stoker	Heavy load	65	65	65
Lads	Odd jobs	26	52	52
Attendant	At sub-station	65	65	65
Ditto	Ditto	—	65	65
		£694	£785	£902

To which it would be wise to add for outside work:

Jointer	£120	£120	£120

It being presumed with regard to the clerical work that it will be done by the present borough officials.

54. In addition to the staff there will be the following expenses:

Coal, 600 tons, 1,050 tons, 1,500 tons at 9s.	£270	£472	£675
Oil, waste, etc.	90	150	200
Repairs	150	250	350
Water	nil	nil	nil
Insurance	20	30	40
	£530	£902	£1,265

Digitized by Google

55. Making a total cost of:

Wages and salaries on station.....	£694 ...	£785 ...	£902
Outside	120 ...	120 ...	120
Materials, repairs, etc.	530 ...	902 ...	1,265
	£1,344 ...	£1,807 ...	£2,287

56. On the above basis the works' costs come out as follows:

Plans.	Production in units.	Cost per unit in pence.
A+D combined	99,100	3·62
B+D ,, ...	156,600	2·79
C+D ,, ...	224,100	2·45

On reference to the table of costs which appears in *Lightning*, it will be seen the above estimates are not theoretical, but are based on experience of works' management, and that lower works' costs prevail in some electricity works producing greater outputs.

Name of company.	Output, B.T.U.	Works' cost per unit. Pence.
Newcastle and District Electric Light Company .	290,469	2 90
Newcastle-on-Tyne Electric Light Company.....	335,141	2·52
Birmingham.....	214,088	2·30
Bradford	401,540	1·96
Liverpool	796,281	1·86

and it may therefore be conceded that as the load on the Wakefield central station increases, the works' costs per unit would gradually decline.

On the other hand, it may be pointed out that in places where the economical system proposed for Wakefield is not in use, higher works' costs prevail.

Name of company.	1892 output, B.T.U.	Works' costs per units, pence.
Southampton	35,537	5·64
Northampton	38,293	4·40
Eastbourne	107,842	4·67
Bournemouth	132,343	4·57

The London stations are omitted in both comparisons as affording no guide to working in Wakefield.

The plan proposed by me appears therefore to entail very cheap costs of working, and if adopted by you, will, I feel certain, place you in the position of having one of the cheapest worked stations (of its size) in England.

The actual financial results to the Corporation would be as follows:

Plans.	Capital outlay.	Margin for providing sinking fund.	Percentage of margin on capital outlay.
A and D combined	£12,650 ...	£883 ...	7 per cent.
B and D ,, ...	£16,400 ...	£2,108 ...	12 ,,
C and D ,, ...	£20,200 ...	£3,315 ...	16 ,,

As, however, the working of the four plants at the time of the top load would leave no margin of reserve, the more prudent plan would be, if the capital outlay under plans C and D be incurred, to keep on the 150-h.p. plant in reserve and, at the time of the top load, to run the three remaining plants 20 per cent. above their normal capacity.

This would yield the following results:

Plan.	Capital outlay.	Production, units.	Costs of working	Revenue B and D combined + 20%.	Margin.	Percentage on capital.
C and D combined	£20,200	187,920	£1,950	£4,698	£2,748	13½%

ARC LIGHTS.

I have made all my calculations on the basis of an incandescent plant. If, however, as suggested by me, arc lights are adopted for public lighting, the cost of working same would be 1½d. per hour, if charged to the public lighting authority at 3d. per unit, which would fully cover the cost, in consequence of the prolonged number of hours of burning. Every arc light would take up as much electrical energy as 15 incandescent lights. I submit plan of the proposed central station, and in conclusion, I beg to say that if there are any points upon which the Electric Lighting Committee would like to confer with me, I shall be happy to keep any appointment that they may fix.

Bermondsey.—Last week the General Purposes Committee of the Vestry recommended that, for the more efficient lighting of Spa-road between Alscot-road and Grange-road, the present lamps should be shifted. After Mr. Paddon had moved the adoption of the recommendation, Mr. Tyler said that he thought this might be an opportune moment to consider the advisability of lighting the baths, Town Hall, and library with electricity. The Chairman said the question would involve considerable expenditure, and Mr. Ecroyd, one of the Library Commissioners, said they (the Commissioners) were not in a position to spend any money on electric lighting, seeing that at the end of the financial year they would have a deficiency of £100. No action was taken on Mr. Tyler's suggestion, and the motion was carried.

COMPANIES' REPORTS.

FOWLER-WARING CABLES COMPANY, LIMITED.

Directors: Wm. Fowler, Esq. (chairman), Walter Chamberlain, Esq., R. W. Eddison, Esq., George Fleming, Esq., the Lord Medway, Geo. F. Smart, Esq.

Report to be presented to the shareholders at the fifth ordinary general meeting, to be held at Victoria-mansions, 32, Victoria-street, Westminster, S.W., on Friday, January 12, 1894.

The directors beg to submit herewith their fifth annual report. As will be seen on reference to the profit and loss account appended, the directors have passed their fees for this year to the credit of this account, which thus shows a net profit of £1,990. 5s. 3d. Out of this profit the Board proposes to write £1,329 off the value of shares in other companies which now stands in the balance-sheet at £2,115, thus reducing this item for next year to £786, at which price they may safely be left for the present, and to carry forward the balance of £661. 5s. 3d. to the credit of next year. These shares in other companies were taken in part payment of contracts, and practically represent the profit on cables supplied. The directors believe that they will earn dividends, and become saleable at par or over in due course, but in the meantime they deem it desirable to reduce the estimated value. On turning to the balance-sheet, shareholders will notice that the directors have placed the whole of the fees, hitherto credited, but not drawn by them, to the credit of that account, and they have thus been able to strike out the balance of loss as it appeared in last year's balance-sheet, and to write off £1,209. 4s. 10d. from the preliminary expenses. No allowance has been made for depreciation of plant and machinery, but all has been fully maintained and repaired from revenue. The stock has been taken with great care, and valued throughout at or below cost. The year has been one of great depression in financial and commercial circles, and all who could have held back orders, as far as possible, for better times, but the Company's business has continued to increase nevertheless, the sales being considerably in excess of last year, whilst the gross profits have, on the whole, and notwithstanding severe competition, been well maintained. In 1892, by circular, and again in their report of last year, the directors pointed out that the capital of the Company was insufficient for its immediate requirements and altogether inadequate to any large increase; they therefore made a temporary issue of £10,000 in 5 per cent. debentures, repayable in September, 1894. With the exception of £1,000 taken by one shareholder, the whole of this amount was either subscribed or guaranteed by directors. In view of the immediate necessity of providing additional capital to meet the growing business of the Company, and to pay off the debenture debt, the directors are negotiating for a fresh issue of £25,000, on debentures to be secured against the general assets of the Company, which in the meantime have largely increased, and afford, in the opinion of the Board, ample security for such an issue. Meanwhile, the directors are still confident that, with sufficient capital and ordinary fortune, the Company's affairs must continue to improve. The general manager's report is appended. The retiring directors are Lord Medway and Mr. Geo. F. Smart, both of whom are eligible, and offer themselves for re-election. The auditors, Messrs. Cooper Bros. and Co., also retire, in accordance with the articles of association, but offer themselves for re-election.

General Manager's Report.—The financial year with which this report deals has seen many further extensive applications of our cables, and we have had a considerable share of the work which has been carried out, but there has been a decided depression in our business, and in telephony, particularly owing to the fact that the replacement of overhead by underground conductors, which is proceeding so actively in every other country in Europe, has been in England very greatly deferred. Everything, however, indicates an early extension of telephonic enterprise, and, as our cables have already secured a leading position, such extension cannot fail to beneficially affect the Company. In all systems of electrical supply of any magnitude, and especially in the municipal lighting stations now spreading all over the country, the cost of the cables forms a very large proportion of the total expenditure, and it is of the first importance that the highest efficiency should be assured. In the competitive battle which wages round these large contracts, some of the older companies enter with a much larger record; we have, notwithstanding, secured several important municipal contracts, and wherever we have had the opportunity, we have at least equalled the best of our rivals' work. Only time is necessary to enable us to equal their records. Our customers among the engineers who carry out the wiring of buildings for the electric light have largely increased during the past year, and a number of extensive factories in this country and abroad have been entirely wired on our system. It is in this branch, however, that we are hampered by the most serious of our difficulties, and it is often impossible to secure the adoption of our lead-covered wires for work of this class. Indiarubber-covered wire, while more expensive, and, we believe, less efficient and permanent than lead-covered wire, is still more economical to fix and manipulate, and it is to be regretted that we have not been able fully to meet the demand for this wire. I hope, however, that we shall soon be able to do so. Meantime, the best methods of overcoming the difficulties in the application of lead-covered wires to small installations have been studied, with a large measure of success. The plant at Woolwich has been most carefully maintained and considerably added to. It has been our aim in the development of this business to closely apply the results of

Digitized by Google

the most recent discoveries in those branches of applied science which have any bearing on our work. In competitive trials against other systems the high efficiency of our manufactures has been repeatedly established. Our progress has not been so rapid as some anticipated, but it has been considerable, and it has been on such safe and firm lines that we have every justification for confidence in the future. ALFRED E. MAVOR, General Manager.

BUSINESS NOTES.

Reading.—A large electric lighting scheme is proposed to be undertaken by a local company.

Great Northern Telegraph Company.—For the month of December the receipts were £20,800.

Buxton.—The Local Board have decided, in connection with their provisional order, to expend £10,000.

Western and Brazilian Telegraph Company.—The receipts for the week ended January 5 were £3,037.

Wigan.—The Library Committee have suggested the introduction of the electric light in the free library buildings.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 7th inst. amounted to £688.

Howth.—The subject of oil or electric lighting is under consideration in this district, which is situated near Dublin.

Vacancy for Pupils.—Messrs. Swinburne and Co., Broomhall Works, Teddington, have vacancies for two premium pupils.

Dalkeith.—The electric light has been fitted throughout the Dalkeith Hotel by Messrs. Fiford and Sons, of Southampton.

Bedford.—It has not yet been decided whether or not to transfer the Council's provisional order to the Bedford Electric Lighting Company.

Eastern Telegraph Company.—The receipts for the month of December were £55,579, as against £59,776 for the corresponding period of 1892.

Eastern Extension Telegraph Company.—For the month of December the receipts show a decrease of £5,389 as compared with the corresponding period of 1892.

Scarborough.—The Town Council have decided to bear the extra cost of laying underground wires for telegraphic communication with the branch post office at South Cliff.

Dover.—It is stated that there was a fair demand for the Dover Electric Light Company's shares, and that although they were not all applied for, the necessary capital will be forthcoming.

Woking.—Tenders are invited, by the 17th inst., for the lighting of the Woking station and Maybury ward for the Woking Local Board. Tenders to be sent to Mr. Robert Mossop, clerk, Woking.

Portsmouth.—The Electric Lighting Committee of the Town Council have been authorised to connect the mains with the technical school in Arundel-street, and with the branch library at Southsea.

Froggatt's Inventions Syndicate, Limited.—This Company has been registered, with a capital of £1,000 in £1 shares, to acquire and develop certain patents relating to methods of generating and storing electricity.

Electric Lighting of Edinburgh.—The Lord Provost's Committee of the Town Council have given instructions to advertise for estimates for the works in connection with the electric lighting of the city, the tenders to be lodged before the end of the present month.

Direct United States Cable Company, Limited.—This Company announces an interim dividend of 3s. per share, tax free, being at the rate of 3 per cent. per annum, for the quarter ending December 31, 1893, payable on the 24th inst., carrying forward £3,080.

Bray.—At last week's meeting of the Bray Township Commissioners, it was announced that the Electric Light Committee had recommended that the town clerk should be authorised to enter into correspondence with electric light contractors for purchase of plant, etc.

City and South London Railway.—The receipts of the Company for the week ending January 7 were £990, against £998 for the same period last year, or a decrease of £8. The total receipts for the first half-year of 1894 show a decrease of £8 over those for the corresponding period of 1893.

Sunderland.—In addition to the tenders mentioned in our issue of the 29th ult. as having been accepted, the tender of Messrs. Doulton and Co. at £807 for stoneware and pipes has been accepted, and also that of the British Insulated Wire Company for potential leads at 10½d. per yard, amounting to £90.

Port Beira Pier, Tramway, and Telegraph Company.—This Company has been formed with a capital of £150,000, in £1 shares, to acquire certain privileges and concessions granted by the Mozambique Company for the construction of piers and landing stages, tramways, telegraphs, and telephones in the port and town of Beira.

Walsall.—The Gas and Electric Lighting Committee of the Town Council have recommended that they should increase the amount of the loan to be asked for the proposed scheme of electric lighting to £21,900, so as to include the estimated value—viz., £2,250—of a part of the Wolverhampton-street Gasworks, intended to be used as the site of the electric generating station. The Mayor advised that the loan should be made £22,000, and this suggestion was adopted.

The Breaking up of City Streets.—Mr. Deputy Scott called the attention of the Commissioners of Sewers on Tuesday to the condition of some of the streets where the paving had been removed by the City of London Electric Lighting Company, and enquired whether there was no power to compel the company to replace the paving. Mr. King said that he thought the time had come when the Court should appoint some inspector to superintend the work of the company.

Stoke.—An electric light installation has been put up at the Stoke railway station, both in the goods yard and approaches. The platforms of the passenger station are now lighted by arc lamps. It is likely the offices and waiting-rooms at the station will soon be lighted by electricity. The North Stafford Hotel, the principal hotel in the district, has been equipped with an electric light installation, and in most of the rooms gas has been replaced by incandescent lamps.

Power Transmission in South Africa.—Messrs. H. Hanbury and Co., in their review of the South African market for 1893, quote the opinion of Mr. W. H. Furlonge, who was delegated by the United States Institute of Mines to report on the mines in the De Kaap district. Mr. Furlonge states that a great drawback to these fields has been the want of cheap motive power, but the electric installation of the Moodies, now approaching completion, will supply the mines of this concession with the necessary power at cost price.

Swansea Harbour.—The monthly meeting of the Swansea Harbour Trust was held on Monday, when the chairman moved

Digitized by Google

the adoption of the report of the executive committee, which recommended that a contract for the working, maintenance, and renewal of the electric lighting machinery and plant be let to Mr. John S. Brown, at £649 per annum. As to the electric lighting, it was pointed out that the trust had in the past been doing the work themselves at a cost somewhat more than that for which Mr. Brown had contracted.

Tenders Wanted for Cheltenham.—As will be seen from our advertisement columns, the Corporation of Cheltenham invite tenders for supplying and erecting engines, dynamos, and boilers at their electric light station. A copy of the specification and any further information may be obtained on application to Mr. Joseph Hall, A.M.I.C.E., Municipal Offices, Cheltenham. Sealed tenders, on forms to be supplied, addressed to the Electric Lighting Committee, and endorsed "Tender for Machinery," are to be delivered at the Municipal Offices, Cheltenham, not later than Tuesday, the 23rd inst.

Bradford.—At a meeting of the Bradford County Council, after the reading of the minutes of the Sanitary Committee, Alderman Smith Feather asked the chairman if he had heard anything of the process for utilising the refuse at the destructors for the purpose of generating electricity. He understood there were gentlemen prepared to carry out the scheme on the "no cure, no pay" system. Mr. Louis Walker (the chairman) said that the system in use at Halifax did not belong to the Corporation, but was being worked by a private firm. He hoped soon to have a sub-committee appointed to enquire into the matter.

Extension of Premises.—The Electrical Installation Company, Limited, of 64, Victoria-street, S.W., inform us that, owing to increase of business, they are extending their premises, and are moving into additional offices at 66, Victoria-street, to which address their general office was transferred on the 8th inst. The company have started works in Pimlico, where they are manufacturing some of their specialities, *inter alia* being their new patent "Vauxhall" arc lamp, the "Britannia" automatic projector for marine and photographic purposes, and apparatus for the application of their system of electric heating.

Situations Vacant.—The Corporation of Wolverhampton invite applications for the post of draughtsman and assistant in the borough electrical engineer's office, at a salary of £90 per annum. Applicants must be capable draughtsmen, and have had technical training in electrical engineering. The Corporation also require applications for the post of working outdoor foreman and linesman, at a salary of £2 per week. Applicants must be steady men, and have had sound practical experience of the wiring and fitting of houses for electric light and power. and also of arc lamps and motors. Further particulars will be found in our advertisement columns.

New Installations.—Mr. E. R. Dolby, C.E., of 8, Princes-street, Westminster, acting as consulting electrician for Mr. S. V. Morgan, has recently completed an installation of 137 lights at 37, Harrington-gardens, South Kensington (Messrs. G. Trollope and Sons, contractors); also about 80 lights in the Economic Life Assurance Society's offices (Messrs. Baily and Grundy, Limited, contractors). He is now acting as consulting electrician for the lighting of Saratoga, Forest Hill, putting in a complete installation, consisting of a Crossley's Otto gas-engine, a Mather and Platt dynamo, E.P.S. cells, and the equivalent of 104 lights, Messrs. Strode and Co. acting as contractors.

Lighting at Belfast.—At a meeting of the Corporation last week some discussion arose on a proposal to adopt new standing orders prepared by the Council in committee. Mr. Masterton moved as an amendment that the order which provided that the Electric Committee should have charge of the superintendence and management of the electric works should be omitted, and that the words "and the electric works" should be added to the one referring to the Gas Committee. Alderman Connor seconded the amendment. Mr. Harrison, who opposed the amendment, said that, as electric lighting was a new department, it should be entrusted to men who had a thorough knowledge of electrical work. The original motion was eventually adopted.

Transmission of Power.—Mr. Dicey, a mining engineer at Barberton, has made the following suggestion to the Pigg's Peak Estate and Gold Mining Company: "I should wish you to consider whether it would not be advisable to increase your milling power to 60 stamps, as it is undoubtedly the quantity, not the quality, of this ore that will pay, the power to run the mill to be transmitted by electricity generated at the falls, thus reducing the working expenses in the mill to a minimum. The two turbines at the falls are capable of running 150 stamps, so the actual cost of working 60 stamps or more is, comparatively, the same as working 40. The turbines, fluming, and everything connected with the water power are in perfect order."

Eccles.—The Town Council last week adopted a resolution authorising the Tramways and Electric Lighting Committee to take such preliminary measures as might be advisable, with the object of carrying out the powers conferred upon the Corporation by the Eccles electric lighting order. Alderman Kendall urged that as the Corporation were bound to carry out the order, which was obtained in June last, within two years, they were forced to take the matter in hand to maintain their right, if they only proceeded to light a portion of the borough. The Corporation, he was told, could not supply 2,000 or 3,000 lights without a loss; but if they could supply 6,000 lights with a profit, and if they could run this up to 13,000 lights, there was a possibility of making a profit of £1,000 a year.

Tenders Required for Hanley.—Tenders are invited by the 29th inst., as notified in our advertisement columns, for the electric light wiring and fittings to the Corporation buildings—namely, (1) Town Hall and Victoria Hall; (2) free library; (3) museum; (4) public baths; (5) vegetable and fish markets; (6) butchers' market; (7) electricity generating station; also for (8) electricity meters, main double-pole switches and fuses, and other stores; and for (9) electrical testing and measuring central-station instruments. Specifications, plans, and particulars may be obtained from Mr. Joseph Lobley, borough engineer, Town Hall, Hanley. A deposit of £1 will be required respecting items 1 to 7, which will be returned on receipt of *bonâ fide* tender. Separate tenders, sealed and endorsed, to be sent to the borough engineer.

City and Guilds Technical College, Finsbury.—A special course of three lectures on "Governing Arrangements of Engines," by Mr. R. G. Blaine, M.E., A.M.I.C.E., will be given on Thursday evenings, from 7.30 p.m. to 8.30 p.m., commencing Thursday, the 18th inst. The following is the syllabus of lectures: Lecture I. — January 18 — Elementary Principles; Centrifugal Force; Rules; Simple Conical Pendulum Governors; Effect of "Loading" a Governor; Fluctuation of Speed; Isochronism; Parabolic Governors; Numerical Examples. Lecture II. — January 25—Hartnell's and other Spring Governors; Automatic Regulation of Expansion by Corliss, Pröell, and other "Trip" Gears; Supplementary Governors and Governor Attachments; Defects of Various Governing Arrangements; the Testing of Engine Governors. Lecture III.—February 1—The Governing of Marine Engines; Balanced and Spring Governors: Pneumatic Governors; "Fluid-Friction" Governers; Governors for Gas and Petroleum Engines; Electric Governors; Conclusions.

Bury.—The Electric Lighting Committee of the Town Council have reported that at a meeting on the 20th ult. it was resolved that the Mayor be the chairman of this committee for the ensuing municipal year. Mr. Cartwright again submitted the schemes and tenders for the lighting of the borough with electric light, and read a report, which incorporated another report drawn by Mr. Wynne, the electrical engineer. Mr. Cartwright informed the committee that Mr. Wynne had convinced him that the continuous-current system was the best, and after reviewing and criticising the various schemes, advised the committee not to accept any of the schemes and tenders sent in, but to allow Mr. Wynne to prepare an entirely new scheme upon the continuous-current system. On the minutes of the Electric Lighting Committee coming up for confirmation last week, Councillor Bentley suggested that the steam needed to drive the engine be generated by waste heat from the destructors. As the destructors were to be erected in the spring, he urged that no time should be lost, and that the committee should meet at the earliest opportunity to consider the question.

Heysham.—Last week a meeting of ratepayers within that portion of the parish of Heysham called "Sandylands," and adjoining the West End of Morecambe, was held at the Cumberland View Inn, to receive the report of the recently-appointed inspectors for the lighting district recently formed under the Lighting Act. Tenders from the Morecambe Gas and Electric Light Companies for the lighting of the promenade and highway from the Battery Inn to Cross Cop were read and considered, after which it was resolved to adopt a scheme of electric lighting, the Morecambe Electric Light Company undertaking to fix and supply 25 16-c p. incandescent lamps during eight months of the year, and in June, July, August, and September substitute for the proposed 10 lights on the promenade an equal number of 500-c.p. arc lamps. For this their charge would be £49 per year; but as this would not cover the cost of installation, they stipulated that the contract be for three years, and that they have the right to supply for private lighting and motive-power purposes within the lighting area. The total cost for gas lighting, including interest on outlay, and providing for lighting, extinguishing, and repairing lamps, was estimated at £95 per year. It is expected that the installation will be completed in 10 weeks' time.

Electric Lighting at Cambridge.—The Town Council last week received a report from the Paving, Drainage, and Lighting Committee. The committee reported that they had considered the report of the Electric Lighting Committee with reference to the application by the Cambridge Electric Supply Company, Limited, to make certain exceptions to the delivery of a constant supply of energy, together with letters from the junior bursar of Trinity College and the secretary to the University Union Society thereon, which report and letters were referred to the committee by the Council on the 14th ult. The Paving, etc., Committee, after consideration of the objections made in the letters above referred to, and to the proposals of the Electric Lighting Committee, recommended that the company be permitted to make the following exceptions to a constant supply: On weekdays, from October 1 to June 25 inclusive, from 2 a.m. to 6 a.m.; from June 26 to September 30 inclusive, from 2 a.m. to 5 p.m.; on Sundays, from April 1 to September 30 inclusive, from 1 a.m. to 5 p.m.; from October 1 to March 31 inclusive, from 1 a.m. to 2.30 p.m. The committee further recommended that it be made a condition with the company that on a demand by any consumer for not less than 20 lights of 16 c.p. for any particular occasion, the supply should be continued until sunrise. After some discussion, the report was adopted, slightly amended.

Bournemouth.—Some discussion took place at a meeting of the Town Council last week on a motion brought forward by Councillor Haydon to rescind the resolution of the Council passed on December 22, 1892, authorising the construction of subways "for the purpose of enabling the proposed fountains to be illuminated with the electric light." Councillor Haydon maintained that the expenditure would not be justified, either on the grounds of necessity or attraction. Councillor Cutler seconded, and said it would have been a different matter if the fountains were to be placed in

Digitized by Google

the winter garden, where people paid for admission. In reply to Councillor Mattocks, the surveyor said the cost of the fountains and the subways was estimated at £900. The fountains were to cost £250 each apart from the electric light work. Councillor Roker said they had already raised a loan of £500 for the fountains, and they could not very well abandon that part of the work, but nobody wished to raise the rates unnecessarily, and he should vote against the additional expenditure of £400 for illuminations. Councillor Hoare thought it much better to do the work now, and he would like to move as an amendment that the chambers for the electric light be put in. Councillor Davis said he would be pleased to second the amendment. The Mayor said he could not receive it as an amendment, as it was a direct negative. After further discussion, the motion was carried.

Lighting of Swansea.—The question of electric lighting, to which we have referred in recent issues, is engaging the attention of the members of the Corporation. The Electric Lighting Committee is composed of some of the most practical men on the Council. The committee is as follows: Aldermen H. A. Chapman (ex-mayor), Richard Martin, M. Tutton, W. Richards, A. Mason, Councillors R. S. Lindley, Thomas Freeman, and G. Morgan. Several meetings have been held: interviews with four different experts have taken place, and every effort is being made to obtain the best and most reliable information. Several schemes have been suggested, but not one has been definitely fixed upon as yet. The attempt on the part of a private company to obtain a provisional order, as against the order granted the Corporation in 1889, has been overcome by the action of the Electric Lighting Committee. Of the different schemes submitted, two include the destruction of the town refuse by destructors. The committee are considering the details of the schemes, but are determined not to adopt one without the advice of an expert. For that purpose they have engaged Mr. Manville, of Messrs. Waller, Manville, and Kincaid, whom they will pay 50 guineas to prepare a report as to the best way of lighting that town by electricity, and of utilising the refuse. It is estimated that the scheme will cost £30,000, and that a sufficient profit will be realised to pay for the lighting of the whole of the streets.

Confirmation of Halifax Tenders. — After considerable difficulty a suitable site for the electricity works has at last been found, and the purchase was confirmed on Wednesday last by a special meeting of the Council. The site, which is about 400 yards from the one originally decided on in Cripplegate, is an excellent one, and has an area of nearly 5,000 yards. Coal can be shot direct into the boiler-house from the railway, and condensing water is plentiful. Two sub stations, each of 100-kilowatt capacity, are now under construction, from which a three-wire network will supply the centre of the town, the outer district being at first served by separate transformers. The Council also confirmed the following contracts, which were given out by the Electric Lighting Committee some weeks ago: Boilers and mechanical stokers: Yates and Thom, Limited, £1,688; Green's economiser: Yates and Thom, Limited, £489; horizontal engines: Pollit and Wigzell, Limited, £1,860; condensers: Pollit and Wigzell, Limited, £225; alternators and exciters: Electric Construction Company, Limited, £2,055 (amended tender); switchboard: John Fowler and Co., Limited, £460; transformers and fittings: C. A. Parsons and Co, £844. 6s.; cables, pipes, etc.: Siemens Bros. and Co., Limited, £7,450; trench digging: Watkins and Wilson, Halifax, under footpath, 9½d. per yard, road 1s. 7d.; two horizontal engines for exciters: Robey and Co., Limited, £317; sub-stations: H. Jenkinson and Co., Halifax, £79. 15s. 8d.

Whitehaven.—The Town and Harbour Trust last week confirmed the minutes of the Electric Light Committee. The minutes stated that the surveyor reported that at present there were 550 16-c.p. lamps supplied with current, and applications had been received for an additional 480 lamps, exclusive of the street and harbour lamps. Mr. Musgrave mentioned that he understood that so far the committee had sufficient power to supply all applications that had been made, and that the committee were making every effort to meet those applications. Of course they understood that in the first year of such an experiment there would be some little difficulties to overcome; but, so far as he could understand, the electric lighting might be considered a success. That being so, he would like to know whether provision had been made for further extension of the private wires throughout the district. The Chairman said, in reply, that the generating machinery was sufficient for the applications at present, but he thought it would be patent to everybody that before next year it would be necessary to put down more plant. The engines were now running almost to their utmost capacity, and they hoped that the accounts on March 21 next would be so satisfactory as to leave no doubt whatever in the mind of any one trustee as to the expediency of duplicating or at all events considerably augmenting their plant. It was not the intention of the Electric Lighting Committee to bring this matter before the Board until they were in a position to give some result of the present year's working.

Lighting at Chester.—A monthly meeting of the Chester Town Council was held on Wednesday, the principal business being a motion proposed by Alderman H. T. Brown that the memorial of the dean and chapter against the utilisation of the Hop-pole Paddock as the site of the proposed electric lighting station be further considered and a reply sent to it. He pointed out that, although the memorial had been presented two months ago, no reply had been sent to the dean and chapter, and in this respect the Council had shown scant courtesy. The memorial, he said, was divided into two parts. The first was a protest against the Paddock being used as proposed, and the second was what almost amounted to an offer from the dean and chapter to concur with the Corporation in securing the Paddock as an open space for the citizens. The Council resolved, by 17 votes to 9, that the Paddock should be the site of the generating station, but he pointed out that the second part of the memorial had not been taken into consideration. He did not wish to reopen the question, and he merely asked that the Council should sanction a reply being sent to the dean and chapter. The Deputy-Mayor admitted that the Council had come to their decision rather hastily. If they had seen the plans he did not think they would have approved of erecting buildings of that character so near the walls, not to speak of the cathedral. Mr. G. A. Dickson seconded the resolution. Mr. W. H. Churton regretted that there should have been an oversight in replying to the memorial of the dean and chapter, and moved that the resolution of the Council be sent as a reply, with an expression of regret that they could not accede to the wish of the memorialists. He assured the Council that the Electric Lighting Committee were not going on with the matter too hastily. Before proceeding further, they were to have an assurance from an expert electrical engineer that there would be no likelihood of damage to the walls or cathedral resulting from the erection of the electric station in the Paddock. They would have no ugly buildings erected which would be a disfigurement to the surroundings, and they wanted the engineer to be responsible for any damage to the walls, the cathedral, or the adjoining property. Mr. W. C. Deeley seconded Mr. Churton's resolution, which was carried.

Battersea and Electric Lighting.—On Wednesday evening, Mr. W. Willis, L.C.C., brought forward two motions, of which he had given notice, at a meeting of the Vestry of the parish of St. Mary, Battersea, the first being to revive the question of lighting the parish by electricity; and the second that a new committee, consisting of five members from each ward, be appointed to enquire fully into the matter, and to report to the Vestry. Mr. Willis stated that on September 23, 1891, he had moved a resolution that it was expedient to seriously consider the lighting of the parish electrically, and that a special committee should enquire into the cost and practicability. The Vestry as a whole was then apparently opposed to the electric light, and the committee having been agreed upon, appointed as its members those who were avowedly opposed to electric lighting. At that time a company, the Putney and Hammersmith Electric Lighting Company, had applied for powers, and the committee reported that they considered the company had precedence of the Vestry, and that it should be allowed to go ahead. This company had abandoned its powers some time ago, and Mr. Willis accordingly proposed the motions which stood in his name, and these were seconded by Mr. Morels. Mr. Taylor proposed as an amendment that the subject should be postponed until a new vestry had been elected in November next, but practically unanimity prevailed in favour of Mr. Willis's proposals. Mr. Cosligan approved of the appointment of a committee, and said there could be no sensible objection to it, as it would simply search for information. The electric light was bound to come in the course of a few years. He, however, thought that a committee composed exclusively of Battersea vestrymen would be of little use, and that they should have an expert as a guide. Mr. Howarth Barnes, who, when Mr. Willis moved the appointment of the original committee, had suggested that its appointment be postponed for two years, now supported Mr. Willis, stating that he thought that immense progress had been made in electric lighting. Mr. Hart was of opinion that if any profit was to be made out of electric lighting, the Vestry should have it, and he adduced statistics showing the success which had been met with in St. Pancras, which was the only London parish which had gone in for electric lighting, and he also pointed to the good results which had been obtained by municipalities in Bristol, Dublin, Brighton, Huddersfield, and other towns. The motions were agreed to, and a committee was appointed consisting of Messrs. Willis, Shutter, Holloway, Clifford Smith, McGill, Marsen, Nelson, Bootle, May, Davies, Hart, Morels, J. H. Hunt, Winchester, Parr, Derby, Scholfield, Mansel, Munslow, and Barnes.

Lighting at Wolverhampton.—Mr. Codrington, one of the Local Government Board inspectors, held an enquiry last week relative to an application by the Corporation for a loan of £30,000 for carrying out an electric lighting scheme in the borough. There was no opposition. The town clerk appeared to support the application, and there were also present the Mayor (Alderman C. T. Mander), Mr. A. P. Brevitt (architect), Mr. R. E. W. Berrington (borough engineer), and Mr. F. H. Lewis (electrical engineer to the Corporation). The Town Clerk said the provisional order under which the Corporation sought to supply the electric light for public and private purposes was granted on August 4, 1890. So far as the electric lighting extension was concerned, the Board's consent had already been obtained to a loan under the Electric Lighting Act for the purchase of land adjoining other land belonging to the Corporation in Commercial-road, and now used as a wharf. A generating station was about to be erected according to plans which had been prepared by the architect (Mr. Brevitt), at an estimated cost of £4,985, according to an accepted tender. The electrical engineer to the Corporation (Mr. Lewis) had had considerable experience, and the Corporation had every confidence in the scheme he had submitted. The central station would, he said, be at the Town Hall, with branch stations at the Art Gallery and the Free Library. It was proposed to light the streets by means of arc lamps. There would be 42 lamps, and 20 of them would be extinguished at 12 o'clock at night, and the others would be left till a later hour. The trunk mains, which were high-pressure feeding and low-pressure distributing, would be so insulated as to comply with the requirements of the Board of Trade, and there would be certain pre-

Digitized by Google

cautions which would prevent any danger. The whole scheme had been submitted to the Board of Trade, and although he had received a reply which was virtually a consent to the scheme, he had not yet had their formal consent, the Board stating that they would be unable to send their formal approval by the date named in his letter. The estimated cost of the scheme was £30,000, of which £17,442. 14s. 2d. was for plant, and £1,320 for arc lamps, and £2,243 would be left for contingencies. With regard to the question of the repayment of the loan, he had written to the Local Government Board asking whether they had any powers to suspend the operation of the sinking fund with respect to this undertaking for a few years, in order to enable the Corporation to turn round during the time between the commencement of the work and the completion of it. He was to ask that the longest possible period which could be should be allowed the Corporation, who were one of the first boroughs in the district to carry into effect the electric lighting order. It was very necessary, in the interests of the ratepayers, having regard to the high rates, that they should have a little latitude in the period allowed for repayment. It was not to be supposed that the Corporation would make instant profit. The first year or two would be very trying. The electrical engineer estimated the dead annual expenditure at £3,307, and to cover this a minimum annual consumption would be required of 193,600 units at 6d. per unit, which was equivalent to the consumption of 5,308 c.p. lamps and 50 arc lamps. Evidence having been given by Mr. Lewis (the electrical engineer), Mr. A. P. Brevitt (architect), and Mr. Howell (borough accountant), in reply to a question, the Inspector said he thought expenditure in the laying out of fittings might be regarded as capital expenditure, and that a loan might be applied for. The proceedings then terminated.

Monmouth.—The Town Council on two occasions last week discussed the questions of sewerage and electric lighting. At the second meeting the Mayor remarked that there was so much to be duplicated in the drainage and electric lighting schemes that it would be well for the members of the Corporation to have a clearer view of the matter than was conveyed in the figures afforded at the previous meeting. He had since gone carefully through them, cut out the duplicates, and divided them into four headings as follows: Sewerage, purification works, lighting, and what he called the junction works—that was, where the schemes touched each other. Under the head of sewerage, the amount for the sewers themselves was £5,425 (these were the figures of the amended schemes now before the Local Government Board), contingencies, £545; compensation, £35; engineering fees, £390; and legal, £70; making a total of £6,465. Under the head of purification works were—tanks and filters, £980; receiving tanks and pumps, £800; rising main, £100; for that proportion of land, £400; ploughing land, mixers, and roads on works, £150; 10 per cent. contingencies, £397; compensation, £15; fees, £190; legal, £30; total £3,062. The items for lighting were—generating plant, with two engines of 70 h.p., one boiler, and three turbines of 70 h p., £4,884; trenching, £250; total, £5,134. He did not approve of some of the items in the junction works; they seemed to him to be unnecessarily expensive. However, the figures were for deepening 700ft. of existing channel, £233; head-race, £1,161; culvert under the railway, £388; tail-race, £317; weir, £68; fish grating, £101; accommodation works over the canal, required by the solicitors to the Duke of Beaufort, £250; land, £162; turbine well, £389; buildings and machinery foundations, £1,000; contingencies, £200; total, £4,269. Colonel Walwyn asked if any agreement had been entered into with the Brush Company. The Mayor observed that they had accepted their tender. Alderman Vizard said that no final agreement with them had been made. The Mayor replied that the selection was provisional. The total sum required to be spent over the two schemes, as they stood at present, was £18,930, which was an advance of £930 upon the figures placed before them before. The difference was to be accounted for in this way. The present tender of the Brush Company was £4,884, and it had been increased to that amount from £4,246, the amount of the accepted tender of November 16, 1893, on account of the fresh demands which had been made upon them. There was a difference of £638. The increase had arisen partly at the instance of the Corporation themselves in view of a reduction in the annual expenditure. There was further £101 for fish gratings asked for, at the head and tail of the race, by the river surveyors; £250 for accommodation works asked for by the agents of the Duke of Beaufort; and £250 for trenching, which originally appeared in Mr. Lailey's scheme, but which had now been transferred to the lighting scheme because it had nothing whatever to do with the sewerage. The Mayor explained the arrangement by which two engines of 35 h.p. each had been adopted instead of one of 60 h.p., and three turbines of 23½ h.p. each instead of two of 30 h.p. The possible reduction in the annual cost when only a small power was required was obvious. Alderman Vizard asked who was responsible to them for the figures relating to electric lighting. The Mayor replied the Brush Company, who gave them the figures. It was eventually decided that a competent engineer be employed to go into the matter, take his own measurements, and give them his own opinion on the figures relating to the project for electric lighting. The Mayor said that under these circumstances the town clerk had better write to the Institute of Civil Engineers at once, and get them to nominate some hydraulic engineer with whom they might get into correspondence as to charges, etc. The town clerk was instructed accordingly.

Lighting of Guildford.—As stated in our last issue, the Town Council have given consent to the application of the Holloway Electricity Company to the Board of Trade for a provisional order, on the understanding that the undertaking may be acquired by the town in 10 years, if such should be deemed advisable. In this connection, the letter read at a meeting of the Council last week from Mr. H. A. Folkard, the secretary of the company, is worthy of note. The letter stated: "It will be within your recollection that in 1882 Parliament passed an Electric Lighting Act which contains a clause enabling local authorities to buy up undertakings after 21 years upon the terms of Section 2 of the Act. This Act so much failed in its object that in 1888 Parliament passed another Electric Lighting Act, which increased the period for compulsory purchase from 21 to 42 years from the date of the order. The conditions of purchase as unanimously agreed to by your Council, and forwarded to this company,, are based on Section 2 of the Act of 1888, with power to purchase the undertaking at the expiration, not of 42 years, nor even of 21 years (which period was considered too short by the Legislature), but after a lapse of 10 years only. Obviously, this condition does not carry out the spirit of the Act, but is, on the contrary, in direct antagonism to it. As this provision, if insisted upon, will entirely check the commencement of lighting in your borough by private enterprise, I am further directed to ask you to lay this letter before the authority at its next meeting, with a respectful request that the members will reconsider our application of the 6th ult., and give such consent as will enable this beneficial undertaking in the town to be carried out." The Town Clerk, after having read the letter, stated that he believed January 15 was the last day for sending in objections to the provisional order, and he thought a committee should consider in some way the form to be agreed on. Alderman Mason moved that the question be referred back to the committee for reconsideration. Councillor Salsbury said he should have no objection to second that, but he did not think it would meet the point unless the committee had power to act, because the Council would not meet for another fortnight, and the time would have elapsed before that. The Town Clerk thought the committee should have power to send in objections, but, of course, the committee could not take power to alter the period. January 15 was not the last day for deciding one way or the other whether they would extend the 10 years or not. Councillor Emery said that 10 years seemed rather a short period. It would be rather unfair to come in and buy up the works at old metal price, and not give the company some recompense for their outlay. Councillor Wrist said he supposed the Council saw no objection to the provisional order; they had all agreed to it. The Mayor explained that, supposing the provisional order were to pass as it was now, there was no term at all. In the general Act of Parliament there was a term of 42 years, but the Council asked that there should be a condition for purchase after the end of 10 years, and every five years subsequently. That had not been inserted, and if they wanted it inserted, or any condition fixing the time at less than 42 years, they must object to it as it stood, because it did not contain anything of that sort. Councillor Bullen presumed it was not competent at that meeting to move an alteration of the period suggested. The Mayor replied that it was not on the agenda. But it did not seem to be essential that they should do it then; there would be plenty of time afterwards, if they chose to lodge any objection. If they were willing to accept the 42 years, they need not trouble to lodge any objection. Councillor Bullen said he must admit that 10 years did seem a short period for persons to come and get all their appliances, etc., and, before the thing had got into good working order, to stand the chance of losing it. A motion was eventually passed referring the subject back to the General Purposes Committee, with power to take such steps as they might think necessary.

Lighting and Traction at Blackpool.—The subject of electric lighting extensions was warmly discussed by the Town Council last week. Mr. Councillor Bickerstaffe referred to the minute desiring Mr. R. Hammond to report and advise the Corporation upon any extensions required in connection with the electric light installation. Before anything was done, he said, he should like to have some idea of what money had been already expended on the station, and some information as to whether the results were likely to pay any reasonable interest for this extra outlay. Pending such explanation he should move that this minute be referred back. Mr. Alderman Parkinson seconded, remarking that they had an electrical engineer who should be capable of advising the Electric Lighting Committee, and he did not see why they should not place the responsibility upon him, and not put another man over his head. Mr. Councillor Ward thought that if the committee looked upon their electrical engineer as incompetent for developing any further scheme, the Council should be acquainted of the fact. Mr. Councillor Heap said that did the members of the Council know exactly the position the committee had taken, that amendment would not be persisted with. The committee had been brought face to face with a greater demand than the present machinery could cope with, and they were simply looking forward to the time when they would have to increase their plant in order to meet the requirements of the town. He could hardly see that the members of the Council were in the entire ignorance they professed on this matter. The committee knew exactly what the station was costing, and what the electric light was costing them. Mr. Councillor Heap, in reply to a question as to why all the information was kept by the committee, said that there was no secresy; every consumer of current knew what he was paying. The committee could see that some extension was requisite, and they were merely proposing to obtain advice from the engineer who had made their installation for them. Their engineer might be as capable of reporting to them as anyone, and might perhaps hold the opinion himself, but they preferred to go to the engineer who had conducted the installation. Mr. Councillor Sergenson said that they had understood for some time that this would be necessary. The Mayor observed

Digitized by Google

that, if he remembered rightly, Councillor Pearson said that such a step would be necessary. He felt very pleased that there was such a resolution on the books; it showed that Blackpool was progressing. Mr. Councillor Bickerstaffe remarked that they were first asked to give them £26,000, and now they would be asked for another £20,000. Mr. Councillor Pearson said that there seemed to be some misunderstanding as to what the duties of their engineer really were. It was perfectly understood when the appointment of a resident engineer was recommended that he should take care of the plant; it was not for the engineer to tamper or tinker with anyone's scheme, a system perhaps which had taken a specialist years to perfect. They did not know what this system would bear in the way of extension, and while the resident engineer might undertake a small extension, it would be better to consult Mr. Hammond as to what was the best to be done. The amount of money which they originally obtained from the Corporation was £26,000, and the likelihood was that before many weeks were over they would have to ask the Finance Committee to negotiate borrowing powers for another £20,000. The consumption of the current was increasing so rapidly that they would have to make an extension which would cause an expenditure of the sum mentioned. This did not startle him, for he could always see from the first initiation that Blackpool would prove an exceptional town, and that the light would be used with avidity. Referring to a promise from the Tower Company, he said that he had been officially notified by the chairman of the Tower Company that if the Corporation could supply them with the light they would take it from the borough; if they could not supply it, the company would no doubt put down their own plant. The committee had estimated the amount of current which they anticipated would be demanded next season, and they found that they would have a demand for nearly double the current which now formed their output. They could tell to a minute fraction what the light was costing them to produce, and they had not placed the figure at the lowest ebb. Then they had to consider that the more consumers they got the more profit they would make, and at less price would they be enabled to supply the current. In his opinion the electric lighting department was going to be a good and profitable concern to the Corporation. He did not know any reason why it should now be challenged, and he could promise them that every matter would be placed before the Council before any further expense was incurred. It was to this end that the committee asked the Council to authorise them to receive a report in a proper manner from the specialist. The amendment was lost, and the minute adopted. With regard to the electric tramcars, Mr. Alderman Buckley asked what was the fee of Mr. M. Holroyd Smith, whom the Electric Lighting Committee proposed asking to inspect the tramway line and plant, besides another inspection by Mr. Thomas Parker. Mr. Councillor Pearson said Mr. Smith's fee was £10. 10s., with out-of-pocket expenses.

The Lighting Question at Newport.—Colonel J. Ord Hasted, R.E., Local Government Board inspector, held an enquiry last week into the application of the Newport Corporation for a loan of £28,000 for electric lighting. There were present at the enquiry the mayor (Councillor F. Phillips), Alderman Moses (chairman of the Electric Lighting Committee), Mr. R. Hammond (electrical engineer consulted by the Corporation), and the borough surveyor (Mr. J. H. Haines). The Town Clerk stated that in the session 1893 three companies applied for provisional orders to supply Newport with electricity, each of which the Newport Corporation opposed. The Corporation was informed by the Board of Trade that the applications would be refused on the understanding that the Corporation would themselves apply for a provisional order in the following session. Accordingly the Corporation sought for and obtained a provisional order in the session 1891. The representatives of the Corporation visited several towns in the kingdom for the purpose of ascertaining which system would be the best to adopt. Eventually, they decided in favour of the high-tension alternating-current system, and they retained the services of Mr. R. Hammond as consulting electrical engineer. The estimate of expenditure put in by Mr. Hammond was £20,000. That was the original estimate sent to the Local Government Board. The Corporation had since then advertised and obtained tenders. As a result of these tenders, it was expected that the original estimate would be exceeded, not by a large sum, but by some amount. As to the prospects of the proposed installation, the Corporation themselves were very large consumers of gas at the various public buildings and institutions of the borough, and, in addition, they had to pay for the gas supply for 800 public lamps in the borough. It was not proposed at the outset to light more than 40 arc lamps in the main streets of the borough, but the whole of the supply they intended to give they hoped would be taken up by the private consumers. The lighting station would be erected on land belonging to the Corporation. Mr. Hammond, who described the scheme, stated that under the provisional order granted to the Newport Corporation the compulsory area included High-street, Commercial-street, Commercial-road, Dock-street, and Baneswell-road, about 5,000 yards in extent. The Corporation, however, desired to place the light at the disposal of as large a number of ratepayers as possible, and had decided to at once lay down mains which would include a total area of 12,300 yards for the purposes of private supply. For incandescent lighting 4,300 yards of mains would be laid, and the Corporation proposed to lay down 4,850 yards of mains for arc lighting. With regard to the means of generating electricity, the site which had been adopted was admirably suited for electrical works. It was close to the Monmouthshire Canal, from which water could be obtained for condensing purposes at a nominal rental of £25 per annum, and there was also a railway running near, by which a coal supply was easily obtainable. With regard to the capacity of the station, the scheme involved the provision of plant for 7,500 lights, all burning at once, and also arc plant capable of running 150 arc lights. This plant would be divided into sections, so that by means of keeping one plant in reserve the chance of breakdown would be avoided and the necessity of storage obviated. The reason for the difference in the original estimate and the present estimate was that the specification had been strengthened. With a view to economical working during the hours of very early morning and until sunset of each day a small engine would be used, so that the cost of running the large engines of 150 h.p. would be avoided. In answer to the inspector, Mr. Hammond said that the scheme had not yet received the approval of the Board of Trade, as they were considering replies to certain questions put by them to the Corporation. Alderman Moses said the Corporation were anxious to proceed with the work as quickly as possible. Mr. Hammond having put in a list of tenders received, amounting to 60, the enquiry then closed. The Town Council, on Tuesday, discussed at some length and warmth the report of the Electric Lighting Committee, who recommended that the all-round tender of Messrs. John Fowler and Co. (Leeds), Limited, at the sum of £23,384 for the whole installation, less the amount of £3,756, the tendered price for cables, should be accepted. The question of accepting a separate tender for the cables having been considered, it was recommended that the tender of Messrs. Siemens and Co. for the cables at the sum of £2,896, subject to the cables being made in England, be accepted. It appeared that the next lowest tender was that of Messrs. Crompton at £20,780. The recommendation of the Electric Lighting Committee deciding to accept the tender of Messrs. Fowler and Co. was ultimately referred back to the committee.

Electric Lighting at Wigan.—When the confirmation of the minutes of the Gas and Electric Lighting Committee of the Town Council was moved last week by Mr. C. B. Holmes, Mr. Laycock stated that he had read the circular that had been issued by the town clerk in regard to electric lighting, and an abstract of which is given below. Mr. Laycock said that some people did not exactly understand it. He took it that at a cost of 2s. 4½d. they got the same illuminating power from gas that they would have to pay 5s. for electricity. Mr. Holmes said he believed that was considered a fair average. Mr. Laycock suggested that before anything was done in the matter a meeting of tradesmen should be called, and all the information respecting the electric light be placed before them. Alderman Phillips agreed with the suggestion of Mr. Laycock, and thought that, if practicable, the electric light should be carried out. He had been informed that the cost of gas was 2s. as against 3s. for electricity. Mr. Holmes, in reply to Mr. McQuaid, said they felt that when the electric light was introduced it would for years be a loss to the town, but it was the general desire that it should be provided by the Corporation. The committee, however, did not want to rush into any extravagant expenditure. He concurred with the suggestion of Mr. Laycock, and thought the meeting might be held in the old Council-chamber. The minutes were confirmed. The circular referred to reminded the ratepayers that in 1890 the Corporation obtained a provisional order, but as there did not then appear to be any general desire on the part of the public to adopt this system of lighting in preference to gas, no electrical works were laid down. The Corporation, however, thought it right to state that they were prepared to undertake to supply electric current in certain streets, if such be the wish of the ratepayers. The town clerk therefore asked the ratepayers whether they would agree to take electric current for lighting purposes, if provided by the Corporation, for a fixed period of three years at 6d. per Board of Trade unit. Continuing, the town clerk says: "I may say that the Board of Trade have made the equivalent of electric current to be 10 units to 1,000 cubic feet of gas. A unit will supply about 30 glow or incandescent lamps of 8 c.p. each, of suitable efficiency for one hour; therefore, as an ordinary efficient flat-flame gas-burner, consuming at the rate of five cubic feet per hour, will be equal to 11 sperm candles power, 10 'units' of electric current will, when supplied to 300 8-c.p. incandescent lamps, give an illumination equal to 2,400 sperm candles over a period of one hour; 1,000ft. of gas consumed by the ordinary efficient flat-flame burners will give an illuminating power equal to 2,800 sperm candles during the same period; the cost of the current being 10 units at 6d. = 5s., the cost of the gas being 1,000 cubic feet at 3s., less 10 per cent. discount = 2s. 8½d.; if, however, the consumer of gas is entitled to 23 per cent. discount, the relative cost would be—electric current, 5s. net; gas, 2s. 4½d. net." With reference to this circular, Mr. G. Stephen Corlett has written to a Wigan paper as follows: "The circular expresses in a remarkably lucid manner the method of arriving at the relative cost of gas and electricity, but I do not think the final conclusions are quite correct—that is to say, the electricity bill will compare more favourably with that of gas than appears from the circular. It is stated that one unit (1,000 watts for an hour) of electricity will supply 30 lamps of 8 c.p. for an hour, which means that the lamps will be working at an efficiency of $\frac{1000}{240} = 4{\cdot}16$ watts per candle-power—a very low standard to take. A few weeks ago I had occasion to test an installation of 950 Edison-Swan 16 c.p. lamps, fitted during the summer by my company, and found the efficiency to work out exactly to 3·75 watts per candle-power. This result can generally be obtained from Edison-Swan lamps, and is about 10 per cent. better than the figures given by the Corporation. But the master patents held by the Edison-Swan Company have recently lapsed, and much more efficient lamps are now available, one type of which, at an efficiency of 2·6 or 2·7 watts per candle-power, has a life of 500 hours, and only costs 1s. 9d. per lamp. It seems to me only fair that, when

Digitized by Google

considering relative cost of gas and electricity, the question of lamp renewal should be taken into account. I do not consider that any fair comparison of light given can be obtained by considering the costs of two fixed quantities of gas and electricity; surely the light from the 1,000 cubic feet of gas will vary according to the state of the burners, and that given by the 10 units of electricity according to the efficiency of the lamps. A lamp of 16 c.p. burning for 1,000 hours at 2·7 watts will take 43·2 units, and will cost for that time, 43·2 units at 6d., £1. 1s. 7d.; two new lamps at 1s. 9d., 3s. 6d.; total £1. 5s. 1d. Taking for gas the figures given by the town clerk—viz., 14 c.p. per hour for 5 cubic feet of gas (probably about the best results possible), it appears $16 \times 1,000 \times 5 \div 14 = 5,715$ cubic feet of gas will be required to give 16 c.p. for 1,000 hours. It should be noted that the price of gas will shortly be raised to 3s. 3d. per 1,000, and I think our calculations should be based on the figure less 10 per cent. If a gas consumer be entitled to 20 per cent., it is only fair to assume that he would have a proportionate reduction on his electric light, as is the custom in most large towns; 5,715 cubic feet at 3s. 3d., less 10 per cent., equals 16s. 7d. So that for a 16-c.p. lamp for 1,000 hours the relative cost would be—gas 16s. 7d., electricity £1. 5s. 1d., or about 33½ per cent. in favour of gas."

The Birmingham and Midland Institute Conversazione.—This conversazione, to which reference was made in our last issue, commenced on Tuesday, and will be concluded to-night (Friday). There is an exhibition of machinery, models, and electrical appliances by the Birmingham Electric Supply Company, Limited, who are supplying the electric current for working the same from their street mains. The arrangements have been carried out by Mr. J. C. Vaudrey, the company's engineer. At two stands, which have been furnished and decorated by Messrs. Norton and Co. as drawing and dining rooms, there is an illustration of the advantages of electric lighting as an illuminant. In the drawing-room the cut glass and fittings have been supplied by Messrs F. and C. Osler. From the centre of the ceiling hangs a magnificent fuchsia-shaped five-light chandelier in cut-glass; there is a handsome electric floor lamp of three lights, and two pendants, while the sideboard contains two table lamps and a couple of crystal vases, which also reflect the electric light. The designs of these lamps are exceedingly rich and pretty, the Moorish pendants and the beautiful Venetian vases being rare examples of skilful workmanship. The floor lamp is portable, and connected to the electric supply by a flexible cord and plug. The dining-room is fitted with copper and brass by Messrs. Evered and Co. A handsome three-light copper and silver plate chandelier ornaments the centre of the apartment. Upon the overmantel are reading lamps, and overhanging the sideboard are a couple of tripod pendants. In another portion of the room the various details of the company's underground system are displayed. There is, first of all, a street service box open for inspection, with the sections of the service line laid bare. The system adopted in making the house connections is illustrated, and the meter shelf, containing a meter and a small section of casing, is exhibited to show the standard method of wiring. There are also various sections of mains shown by the Callender Bitumen Company, Limited, who are the contractors for the laying of the mains in Birmingham. Two types of meters used by the company, and lent by Messrs. Chamberlain and Hookham and Messrs. Ferranti, are exhibited on an adjoining stand—one with the interior exposed and the other in pieces. The company have between 300 and 400 such meters in use. Stand 5 is entirely devoted to illustrations of the method of using electricity as a motive power. Small motors are exhibited, driving direct the following machinery: 30in. lathe, lent by Messrs. James Archdale and Co.; jeweller's lathe and jeweller's drill, lent by Messrs. C. Churchill and Co.; buffing machine, lent by Mr. G. H. Johnstone: hair-brushing machinery, lent by Messrs. Osborne, Garrett, and Co.; Blackman ventilating fan, lent by the Blackman Ventilating Company; Sturtevant blower, lent by the General Electric Company, Limited, London; dental lathe and dental drill, lent by Messrs. Cuttries, Wallis, and Co., Limited, Leeds; and a Singer sewing machine, lent by Mr. Henry Lea, M.I.C.E. This last exhibit will be specially interesting to ladies. The electric motor is mounted upon a rocking frame, which is connected by a cord to the ordinary treadle. The treadle is not continuously worked up and down by the foot, as is commonly the case, but is simply held down by the foot as long as the machine is required to work. A single movement of the foot thus successively performs the three operations—it takes off the brake, turns on the electric current, and tightens the driving belt. When pressure of the foot is removed, a coiled spring slackens the driving belt, cuts off the electric current, and applies the brake. In either case the three operations are performed apparently instantaneously by the slight movement of the foot. Motors for machines have been lent also by Messrs. Crompton and Co., Limited, and the Electric Construction Company, Wolverhampton. To enhance the value of these exhibits the speed and approximate power of each motor is indicated on the stands. Another part of the room is fitted up as a kitchen wherein heating and cooking by electricity are practically demonstrated. The apparatus has been lent by Messrs. Crompton and Co., Limited, of Chelmsford and London, and the cooking is carried out under the superintendence of Mrs. Seaton, London. Various other appliances, lent by the General Electric Company, are shown at work. The Edison-Swan Company have lent a collection of incandescent lamps from 2,000 c.p. to 8 c.p. A most interesting side show is made up of a historical collection of incandescent lamps belonging to Mr. J. C. Vaudry, M.I.C.E., the Birmingham Electrical Supply Company's engineer, under whose direction the whole of the arrangements in this department have been carried out. Four types of arc lamps—the Brockie-Pell, Crompton-Pochin, Luna, and the Mathieson—used on the circuits in the town are shown mounted and with the works exposed, and several examples of standard electric light fittings complete the exhibits in the electricity department. An attraction on Tuesday was the telephonic transmission of musical and theatrical performances from the Metropolis and some of the principal towns in the country, in connection with the National Telephone Company's system. The rooms in which the receivers were placed were crowded throughout the evening, and the visitors thoroughly enjoyed the novel experience of listening to operatic and pantomime work in distant towns. The pantomimes at Liverpool and Manchester, nearly 100 miles off, were clearly heard; and the institute was also connected with the theatres at Bristol, 99 miles distant; Gloucester, 60 miles; Cheltenham, 50 miles; Leeds, 136½ miles, and Newcastle-on-Tyne, 235½ miles. The distance did not seem to matter, for one performance appeared to be heard as well as another. The telephone was also connected with the house of Dr. Taylor, Stafford, where a concert of vocal and instrumental music was heard splendidly.

Electric Lighting of Brighton.—A special report of the Lighting Committee, presented at a meeting of the Town Council last week, recommended the purchase of the goodwill of the Brighton and Hove Electric Light Company, Limited; that application be made to the Local Government Board for sanction to borrow further moneys for electric lighting purposes; that additional mains be laid and additional plant provided; and that the Council, by special resolution, direct an extension of the present area of supply under the Brighton Electric Lighting Order, 1883. The report having been received, Alderman Moon moved the first resolution—namely, "That the Council agree to purchase the goodwill and business of the Brighton and Hove Electric Light Company for the sum of £5,000, subject to the terms set out in the draft agreement, and that the town clerk be authorised to fix the common seal of the borough to an engrossment of such agreement." Mr. Moon thought it would be necessary for him to go over some of the old ground. It would be recollected that some two years ago the Lighting Committee entered into negotiations with the Hammond Company for the purpose of taking over their business and undertaking. These were the instructions of the Council in April, 1891, and accordingly the Lighting Committee appointed a sub-committee to negotiate with Messrs. Hammond for the purchase of the company's business. Messrs. Hammond asked for £17,500, and it was only after a very lengthy discussion and correspondence that eventually the sub-committee got the price asked reduced to £7,000. With that amount they came to the Council in November, 1891, and advised the Council to take over the Brighton and Hove Electric Light Company's undertaking at that price. He regretted to say that at that time the Council could not see their way clear to adopting the suggestion of the Lighting Committee. The committee were perfectly unanimous that it was the best thing to do, but the Council rejected the proposal. Since then they had had to oppose the company before the Board of Trade and in Parliament on their applications for provisional orders. They had also had to compete with them in their business. But to this time they had had no further practical communications with the company on any basis of purchase until, as would be seen from the report, they had a communication from Mr. Sneath, the receiver appointed by the Court on behalf of the debenture-holders, asking them if they would be inclined to take over the undertaking. Mr. Sneath then offered that they should take it over for £7,000, which was the old price, and the committee did not feel disposed to recommend the Council to give that amount at present. They accordingly suggested £5,000, and he had now very great confidence in submitting that to the Council. He found, on referring to the company's statement, that in September, 1891, at the time when the committee were proposing to take over the business for £7,000, the company had 8,168 lamps, and that the consumption on these was 67,000 units. That was the official statement, and he supposed it was accurate. Now, in September, 1893, he found that that had increased to 9,665 lamps, with a consumption of 154,000 units. Therefore the committee were now proposing to give them £5,000 for what approximated to the difference between these figures. He might say, however, that part of these lamps were in Hove, and they did not propose to take that part over. £5,000 would not be a large sum to give the company for their undertaking, and the report showed that they would be able to make a profit of something like £585 a year on the company's lamps, and that in the short time of 10 or 11 years the whole amount would be wiped off. He had all the more reason for recommending this to the Council because of the position that they themselves held. They would remember that the Corporation commenced their undertaking in 1891, and that in running the light from September to December, 1891, they made a deficit of £283. 10s. 6d. That was for three months. Then during the year 1892, after paying all expenses—all capital charges, interest charges, maintenance, and everything that could be properly charged to the undertaking—they made a profit, entirely unanticipated by any member of the Council or of the committee, of £12. 5s. 3d. At that time they made up their minds that they would reduce the price to the consumers, and the committee recommended that the price should be lowered from 7d. after the first two hours to 3½d. About 150 consumers had participated in this reduction of the price, and it resulted in reducing the average cost to every customer to 6$\frac{1}{10}$d. Notwithstanding that reduction in price, according to the estimated balance-sheet that had been given to him by Mr. Wright, it was shown that the estimated profit in 1893 would be £432. 4s. 11d. He could not say that that would be the exact amount, but he had every reason to believe that that would be within the actual figures.

Digitized by Google

Thus, notwithstanding the large amount laid out on this undertaking, they would see that the committee had run it in a commercial and successful manner, and it could be, if necessary, appropriated to the reduction of the rates, for he had no doubt that next year would show a very much larger profit. The purchase-money they asked for was £5,000, and for additional mains and plant for supplying the company's customers £19,227. This estimate was prepared by their engineer, Mr. Wright, but, as they would see by the report, the committee had thought it wise to consult Prof. Kennedy. With one or two exceptions, the professor practically agreed with Mr. Wright's report. Mr. Wright recommended three-wire low-pressure mains for the Kemp Town district, and to feed these distributors two split feeders. Prof. Kennedy quite agreed with this method of supplying Kemp Town, but, instead of taking two feeders, he saw his way clear to supplying the district with one feeder split into three parts, one going to Bristol-road, another to Paston-place, and the third to Chichester-terrace. That, of course, would effect an economy to some extent. Then, to carry the system into the Lewes-road district, what Mr. Wright recommended involved the laying down of a very heavy and expensive feeder. Prof. Kennedy thought it would be more economical to supply this district with a small section feeder on the high-pressure system, carried underground in iron pipes; while with regard to Preston he would apply the same system that Mr. Wright had already recommended, with a loop to connect Lewes-road and Preston. These alterations were expected to result in a saving of £2,600. Thus, under this heading, they ought to deduct £2,500 or £2,600 from the £19,227. The plant and mains for supplying the Preston district were estimated to cost £4,290, and the cost of laying on new house services and purchasing additional meters was estimated at £6,483, the total estimated cost being £32,500 It was not necessary to lay out the whole of that amount simply to take over the company's customers. They were now providing not only for those customers whom they should get from the company, but they were looking forward for four or five years to come. They were in these estimates providing for 7,500 lamps, which was 6,107 more lamps than the company now had in the outlying districts. The light was now an established success, and it would be a very wise thing for the Corporation to take over the company's business, for although up to the present time the company was not doing so well as it might, yet it was very conceivable, and, indeed, very feasible, that if they liked to take away their old plant and put in better, they would be able to carry on the business successfully, and be a successful opponent to the Corporation. It would therefore be wise for the Council to get the whole business in their own hands. Councillor Ballard said he did not think the report should go forward without some criticism, not necessarily of a hostile character. They were asked, he said, to give the company £5,000 for no property whatever, only the goodwill. They were not taking the engines, or wires, or posts, or anything, but merely taking over the company's customers at the company's price; and he was afraid those prices would not be found very remunerative, especially some given lately in opposition to the Council. He believed competition a healthy thing, if there was not too much of it. Rather than the present scheme he would see the committee carrying on the company's installation, and replacing it as they found streets or districts would be better served otherwise. Alderman Reeves congratulated the committee on the decision they had arrived at, adding that he believed it to be a sound business transaction. After further discussion the report and the resolutions were unanimously adopted.

PROVISIONAL PATENTS, 1894.

JANUARY 1.

4. **Improvements in electricity meters.** Albert Ebenezer Schurr, Lyncot, Leigh-on-Sea, Essex. (Jules Cauderay, Switzerland.)
6. **Electrically-heated brands and stamps.** Gustav Binswanger, 71, Queen Victoria-street, London.
12. **Improvements in electrical indicators.** Alexander William Stewart, The Crescent, Dalmuir, Dumbarton.
46. **Improvements in electrical apparatus for controlling traffic on single lines of railway.** William Robert Sykes, jun., and Arthur George Evans, 70, Palace-chambers, Westminster.
57. **Improvements in electric motor apparatus.** William Armour Johnston, Arthur William Browne, and John Clarence Davidson, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)
62. **Improved method of and apparatus for synchronising alternating-current dynamo electric machines, and switching them on and off mains.** John Augustin Kingdon, 28, Southampton-buildings, Chancery-lane, London.
67. **Improvements in and connected with arc lamps.** Louis Carl Henry Mensing, 166, Fleet-street, London.

JANUARY 2.

92. **An improved bracket or hanger for electric lamps.** John Peter Hebendahl, 89, Chancery-lane, London.
95. **Improvements in telephonic transmission and in the art generally of distributing or transmitting alternating currents for power and other purposes.** William Hain Eckert, 52, Chancery-lane, London. (Complete specification.
130. **Improvements in electric light appliances.** Alfred Henry Wildy, 18, Buckingham-street, Strand, London.
135. **Improvements relating to the transmission of electric currents and to conductors therefor.** Michael Idvorsky Pupin, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)
139. **Improvements in telephone exchange systems.** Romaine Callender, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)
140. **Improvements in telephone exchange systems.** Romaine Callender, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

JANUARY 3.

191. **Improvements in dynamos.** Nathaniel Shepard Keith, 24, Southampton-buildings, Chancery-lane, London.
192. **Improvements in electric drills or reciprocating motors, and in dynamos for working the same.** Nathaniel Shepard Keith, 24, Southampton-buildings, Chancery-lane, London.

JANUARY 4.

205. **Automatic compensators for neutralising the magnetic effects of dynamos and motors on board ships.** Sydney Evershed, 1, Woodfield-road, Harrow-road, London.
207 **Improvements in electrical transformers and apparatus connected therewith.** Sebastian Ziani de Ferranti, 27, Charterhouse-square, London.
214. **Improvements in apparatus for transmitting movements for actuating mechanism at a distance, for telegraphing, indicating, and for analogous purposes.** Stephen Alley, 87, St. Vincent-street, Glasgow.
249. **Improvements in electric switching apparatus, more especially intended for use on electrically-propelled vehicles carrying both the source of electricity and the motors.** Frank King, 47, Lincoln's-inn-fields, London.

JANUARY 5.

267. **An improved electric bell indicator.** William Valentine Hunt and William Hunt, 21, Sangora-road, Clapham Junction, London.
294. **Improvements in type-printing telegraphic apparatus.** William Phillips Thompson, 6, Lord-street, Liverpool. (Johann Kustermann, Germany.)

JANUARY 6.

334. **Improvements in fastenings for electric light shades or globes.** Philip Henry Jauncey, 51, Lozells-road, Birmingham.

SPECIFICATIONS PUBLISHED.

1892.

23460. **Electromotors.** Barnett.
23774. **Electric arc for lighting.** Niewerth.

1893.

601. **Electric incandescent lamps.** Hughes.
775. **Electric arc lamps.** Conrady.
1661. **Electrolytic apparatus.** Andreoli.
1683. **Electric arc lamps.** Lott.
2272. **Electric light hangers.** Holt.
3118. **Electrical conductors.** Edmunds.
3119. **Forming solid ends on electrical conductors.** Edmunds.
3152. **Electrical pendulum indicator.** Beal.
7600. **Electrical heating apparatus.** Salomons.
16226. **Electric cars.** Egger and others.
18064. **Electric switches.** Edison and Swan United Electric Light Company, Limited, and Bell.
18990. **Electrically heating or working metal.** Thompson. (Coffin.)
20408. **Ear-pieces for telephone receivers.** Kinniburgh.
21324. **Electric cables.** De Ferranti.
21628. **Telegraphy.** Delany.

NOTES.

Afghanistan.—The electric light and the telephone are used in Cabul.

Sweet Violin. — Violin playing by electricity is reported as the latest move.

Hyde Park.—The new sanitary building erected near the Marble Arch is lighted by both electricity and gas.

Electric Cranes.—The two electric cranes now fitted on the Town Quay at Southampton are reported to have stood all tests.

The Dangers of Coal Gas.—A manhole cover in connection with the St. Pancras electric lighting mains in Endsleigh-gardens was blown up the other day.

The Leeds Tramways.—The *Yorkshire Post*, in a series of articles on the future of the Leeds tramways, discusses the various systems of traction in use in different countries.

New Calendar.—We have to acknowledge receipt from Mr. C. Rettie of a wall calendar, showing the application of electricity to shiplighting and electric traction on tramways.

Traction at Bristol.—The Sanitary Committee of the Corporation have under consideration a proposal to introduce the trolley system on the projected extension of the tramways.

Society of Arts.—On Monday, at 8 p.m., the first Cantor lecture on "The Detection and Measurement of Inflammable Gas and Vapour in the Air," by Prof. Frank Clowes, D.Sc., will be delivered.

Dynamo and Transformer Construction.—Mr. James Swinburne is now giving a course of lectures on "Dynamo and Transformer Construction" to the students of the Electrical Standardising, Testing, and Training Institution.

Personal.—Mr. Gisbert Kapp is now in Germany, where he has gone to inspect the electrical plant contracted for by Messrs. Siemens and Halske for the Cape Town Corporation. The machinery comprises a combined steam and water-power plant.

Cost of Traction on Tramways.—The cost of haulage on the lines of the London Tramways Company, whose system of 23½ miles, with the exception of three miles operated by cable, is worked by horses, amounted to 8¾d. per mile run during 1893.

Award.—Mr. Robt. Thompson, chairman of the North-East Coast Institute of Engineers and Shipbuilders, announced on Tuesday that Mr. J. Brentnall Duckitt was a successful candidate for graduate award for his paper on "Continuous-Current Dynamos."

Book Received.—"Electric Waves," being researches on the propagation of electric action with finite velocity through space; by Dr. H. Hertz. Translated by Prof. D. E. Jones, B.Sc., with a preface by Lord Kelvin, P.R.S. (London: Macmillan and Co. 10s.)

The Institution.—An ordinary general meeting of the Institution of Electrical Engineers will be held on Thursday next, the 25th inst. A paper by Mr. W. H. Preece, C.B., F.R.S., past-president, will be read on "Notes of a Trip to the United States and to Chicago, 1893."

The Antwerp Exhibition.—On Saturday a meeting of the London Executive Committee of the forthcoming international exhibition at Antwerp was held at the Mansion House. A public meeting is to be held at the Mansion House on the 25th inst., at three o'clock, to further advance the interests of the British section.

The Electro-Harmonic Society.—As stated in our last issue, the next smoking concert of this society will take place on Friday next, the 26th inst., in the Banquet-room of the St. James's Hall Restaurant, Regent-street, W. The programme of the concert, which will commence at eight o'clock, is an attractive one. It was printed in our last issue.

The Junior Engineering Society.—To-morrow (Saturday) afternoon, the 20th inst., at 3 p.m., a visit will be paid to the engineering laboratories, workshops, etc., of the Battersea Polytechnic Institute, Battersea Park-road, S.W. At the last visit of this society an inspection was made of Mr. Peter Mumford's Royal Flour Mills, Vauxhall.

The "Medical Battery" Company, Limited.—On Wednesday, at Marlborough-street Police Court, Mr. Hannay resumed the hearing of the charges of conspiracy to defraud made against Messrs. Harness, M'Cully, and Hollier. The case for the prosecution was concluded last week, and on Wednesday the case for the defence was commenced.

Berliner's Telephones.—A new illustrated list of Berliner's telephones has been issued by Messrs. O. Berend and Co. The list deals with telephone sets for domestic use, improved Blake transmitter combinations, battery sets, transmitters and receivers, and telephone exchanges, etc. We are informed that the firm's telephones received the only reward given for microphones at the Chicago Exhibition.

New Type of Reflector.—We have received particulars from Messrs. J. Gill and Sons, of West House Works, Heckmondwike, of a new reflector arrangement for lighting, applicable both to gas and electrical illumination. It is claimed that this appliance absorbs all tobacco smoke, and that it transforms into pleasant and agreeable rooms those places which are under ordinary conditions stuffy and uncomfortable.

The Pacific Cable.—Mr. Sandford Fleming, who is now on his way back to Canada after paying a visit to the Australian Colonies, is enthusiastic about the scheme for an "all-British" cable across the Pacific. Mr. Fleming figures it out that messages could be sent between England and Australia over the proposed Canadian Pacific cable for about 3s. 3d. a word, as against the present rate of 4s. 9d. a word over the Indian Ocean wires.

Lines of Equal Magnetic Declination.—The *Colliery Guardian* has forwarded us a map showing lines of equal magnetic declination or variation of the compass corrected to the beginning of January 1. The lines, which are shown in red on the map, depend, as in several past years, on the magnetic survey of the kingdom undertaken by Profs. Rücker and Thorpe, as published in the *Philosophical Transactions* for the year 1890.

Electric Traction at Bristol.—A deputation from Bristol, representing the Kingswood and St. George's Urban Sanitary Authorities and the Bristol Tramways and Carriage Company, Limited, have paid a visit to Walsall to inspect the overhead electric system of the South Staffordshire Tramways Company, in view of the fact that arrangements are in progress for the introduction of a similar system in the two districts in question.

The Santiago Mining Exhibition.—The Department of Science and Art has received through the Foreign Office a despatch from her Majesty's Minister in Chili, in which it is announced that the opening of the Santiago (Chili) Mining and Metallurgical Exhibition, 1894, has been postponed from April until September of this year, but

Digitized by Google

that, notwithstanding this deferred date of opening, all proposed exhibits can at once be forwarded to Santiago.

Regent-street Polytechnic.—On Monday evening a social reunion and distribution of prizes to the students of the mechanical and electrical engineering classes took place at the Regent-street Polytechnic. There are, it seems, some 350 pupils in the former class under Mr. Henry Spooner, and 300 in the latter under Mr. W. Hibbert. Attached to the electrical department are two physical laboratories, one for elementary and one for advanced students.

Telephonic Communication with Lightships.—The last of the difficulties which have so long stood in the way of the completion of the arrangements for the telephonic connection of the Goodwin lightships with the shore are now removed. The Ramsgate Corporation have granted the necessary permission for carrying the wires through to the town post office. The connection will be direct between the North Sand Head lightship and the Ramsgate Post Office.

Electric Traction at Hartlepool.—We understand that a syndicate has been formed which has purchased the Hartlepool tramways for the purposes of equipping them with the overhead system. The promoters appeared before the Works Committee of both West Hartlepool and Hartlepool Corporations on the 11th inst., and after having explained their intentions, the committee decided to report in favour of the proposition to the Council. We are informed that the tramway system is to be considerably extended.

The Hermite Process.—Preparations for the forthcoming experiments in electrical sanitation are proceeding at Worthing, and operations will probably be commenced about a week or ten days hence. When all the arrangements have been completed, M. Hermite will come from Paris to superintend the tests, which will probably be witnessed by a large number of people interested in sanitary science, applications for permission to be present having been received from many parts of the country.

Derry.—The secretary to the Port and Harbour Commissioners has communicated to the latter a letter from the Board of Trade relative to the inspection of cattle after sundown by means of the electric light. At present, when cattle arrived in the port for shipment to England or Scotland after sunset, they cannot be inspected, and must be kept for 24 hours longer, at expense to the shipper. The secretary has been instructed to write to Belfast to know what was actually required in the way of electric light, and then to ask the Corporation of Derry on what terms they could supply the light on the quays.

South Wales Engineers.—A new building in Park-place, Cardiff, which is now to be the headquarters of the South Wales Institute of Engineers and the Monmouthshire and South Wales Coalowners' Association, was opened last Friday. Besides being lighted with gas in certain parts, the building has been equipped with a complete electric light installation by Messrs. Verity and Co. It is intended to have the electric supply from the Corporation system when it is complete and in working order, but at present it is obtained from Cardiff Castle, through the kindness of the Marquis of Bute. In the evening, a conversazione was held. Prof. A. L. Selby, M.A., in the absence of Principal Jones, gave a demonstration of the projection of the electric arc, and much interest was centred in the various exhibits.

The Government and Telephony.—Notice of motion has been set down by Mr. Provand, M.P., for next session of Parliament that a select committee be appointed to enquire into and report upon the proposed arrangements between the Post Office and the telephone companies as to the working and all other agreements between the telephone companies; and generally on the future policy of the Post Office with reference to the extension of the telephone service. The *Pall Mall Gazette* understands that although the terms of the agreement between the Post Office and the National Telephone Company have not yet been submitted to Parliament, they have been practically settled, subject to ratification by the Department after the House of Commons has had the promised opportunity of discussing them.

The Halifax-Bermudas Cable.—A *Times* correspondent states that strong pressure is being brought to bear upon the Canadian Government by business men in Canada to induce it to grant the extension of the Halifax-Bermuda cable to Jamaica. The leading shippers have been interviewed on the subject, and they hold the extension of the cable to Jamaica and other islands to be absolutely essential to the development of Canadian trade. Four steamers a month are now running from Halifax to those islands, but business is very much restricted by the high telegraph rates charged, and by the fact that the daily quotations of prices published in the West Indian newspapers come from New York. The extension of the Bermudas cable would make it possible for the Canadian market prices to be published in the West Indies side by side with the American quotations; and with the advantage of cheaper cable rates Canadian trade would be largely increased.

The Newport Tenders.—The Parliamentary and Improvement Committee of the Newport Town Council sat for some time on Tuesday to reconsider the tenders sent in for electric lighting plant. It will be remembered that at the monthly meeting of the Corporation last week the Electric Lighting Sub-Committee recommended the acceptance of the tender of Messrs. John Fowler and Co., although their tender was more than £2,000 above that of Messrs. Crompton and Sons. The Corporation refused at that meeting to adopt the recommendation of the committee, but referred the matter back so that Messrs. Crompton might be heard in answer to certain observations made with reference to their plant by the consulting engineer. One of the firm of Messrs. Crompton and their South Wales representative, Mr. Howell, of Llanelly, attended before the committee, and a protracted discussion took place, but no decision was arrived at, the matter being adjourned for a week.

Royal Meteorological Society. — The annual meeting of this society was held on Wednesday evening at the Institution of Civil Engineers, Westminster, Dr. C. Theodore Williams, president, in the chair. The council in their report stated that the society had made steady and uninterrupted progress during the year, there being an increase in the number of fellows, and the balance of income over expenditure being greater than in 1892. They also reported that Dr. C. Theodore Williams, previous to vacating the office of president, had expressed a desire for the formation of a fund for carrying out experiments and observations in meteorology, and that he had presented to the society the sum of £100 to form the nucleus of a research fund. The president, Dr. C. Theodore Williams, in his valedictory address gave an account of the climate of Southern California, which he made most interesting by exhibiting a number of lantern slides. Subsequently, Mr. R. Inwards, F.R.A.S., was elected president for the ensuing year.

Fire Brigade and Telephony.—Captain Simonds, in his report for 1893, issued on Monday, says: "Early in the year an important change was made in the system of

Digitized by Google

providing against a breakdown in the direct telephonic communications between the headquarters and the superintendents' stations. For this purpose there used to be loop lines and instruments connecting each district with those adjacent to it. This method necessitated the message being repeated four times, causing considerable delay and increasing the risk of errors being made. Duplicate direct wires between headquarters and each superintendent's station, run on different routes to the original wires, have been substituted for the loop-lines, and are found to be much more convenient. A signalling apparatus, in connection with the telephone wires, has been established throughout the A district, whereby considerable time is saved in getting help on to fires. The telephones at the Manchester-square station have at the same time been rearranged. These changes will be extended to the other districts as soon as the necessary instruments can be supplied."

Accumulator Traction.—Mr. L. Epstein has written a letter to the *Standard* in reference to an article on different systems of electric traction that appeared in the leading columns of that paper on the 6th inst. He says: "It seems to me that too much stress is laid by the writer upon the objection to the use of accumulators on account of their great weight and the cost of renewing them. With regard to the first, it should be remembered that the additional weight of an accumulator car (an electric car being in any case much heavier than a car drawn by horses) is only about 20 per cent., and, as regards the cost of renewal, practical working has established the fact that the maintenance rate of 1½d. per car mile leaves a very fair margin of profit. Now, all the other items of expenditure being known, and accumulator-makers being willing to undertake the maintenance, it can be shown that the cost of working a tramway line by accumulators is not more than if the same line be worked by a system in which the current is conveyed from a distance. As regards the cost of installation, an accumulator line compares favourably with a direct system, such advantage being, of course, still more marked in the case of conversion of an existing horse tramway."

The Fatal Accident in Blackfriars.—The inquest as to the death of Frederick W. Ball, who was killed at the Blackfriars station of the London Electric Supply Corporation on September 12 last, was resumed and concluded on Monday at Guy's Hospital. The enquiry had been adjourned twice for the attendance of Ernest Meech, who was injured by the electric current, and had since been in hospital. After Meech had given evidence, the jury ultimately returned a verdict that they were of opinion that Ball met his death accidentally by electricity; that had proper precautions been taken to provide the men with gloves the fatality might have been averted; that the rules and regulations should have been printed; and that Meech should have been more competent. With regard to the suggested use of indiarubber gloves, there is little doubt that the provision of gloves would induce a false feeling of security, and dirt on the gloves might lead to a man receiving a fatal shock. As to printed rules and regulations, the men engaged in the transformer stations are experienced and thoroughly understand their duties, knowing full well that they must not touch the transformers when the current is passing. This is the main safeguard.

The Liverpool Electric Railway.—Mr. Wm. B. Forwood, the chairman of the Liverpool Overhead Railway Company, has addressed to the secretary of the Electric Construction Company a letter of which the latter will be justly proud, and particularly Mr. T. Parker, the engineer and works director. In fact, it would be difficult for a higher compliment to be paid than that contained in the communication in question. Mr. Forwood and his colleagues express their satisfaction with the manner in which the company has fulfilled its contract with the electrical equipment of the railway. The directors state that the machinery has been well and substantially made; that it is economical in working; and that its efficiency may be gauged by the fact that during the 10 months the line has been opened a five minutes' service of trains has been run, and 96 per cent. have been on time. They also say that they considered that the generating station has proved its capacity and reliability, and they have, therefore, relieved the contractors of its charge. The directors are of opinion that these excellent results are very largely due to the scientific skill, thorough and untiring industry of the works director, Mr. Parker, to whom they asked the secretary to convey their thanks.

Electric Traction in Birmingham.—A short time ago the Central Tramways Company approached the Public Works Committee of the Town Council with a view to obtaining sanction to the adoption of the trolley system of working electric cars. The committee were also asked to inspect the working of the system at Walsall. Members of the committee recently visited Walsall, but on Monday the committee decided that they could not consent to the application. The principal objection is said to be the unsightliness of the poles and wires. In this connection a Birmingham paper states that the directors of the tramway company are much disappointed at the committee not consenting to the adoption of the overhead system. Continuing, the same paper says: "The present cars, worked by accumulators, entail a considerable loss. In view of this it was in contemplation to reduce the service to one of four cars, making a journey each way every half-hour during the period between now and the autumn, by which time the new system could have been brought into use. This would have lengthened the life of the accumulators at present belonging to the route, so that no additional capital expenditure would have been entailed for fresh ones. Under the new circumstances we learn that it is not improbable that the service of electric cars will have to be reduced to three vehicles."

The Testing of Electrical Instruments.—The Physical Laboratory Testing Department of Owens College, Manchester, is prepared to test a limited number of electrical instruments, free of charge, under certain conditions. The results will be embodied on a certificate which will bear the college stamp, and the certificate will only contain a statement of the results of experiments made with the instrument, and no opinion will be expressed as to its value or construction. The electrical standards of the laboratory will be compared from time to time with the standards of the Board of Trade, and every effort will be made to ensure accuracy; but the college incurs no responsibility with respect to the correctness of the figures given in the certificates. The college will test direct-current meters up to 100 amperes, and give the corrections to the instrument both for descending and ascending currents at definite points, which, for each instrument, shall number not less than three and not more than 10. Alternate-current meters will also be tested as far as the resources will allow. Voltmeters will be tested up to 200 volts, and before long the testing may be carried to 1,000 or 2,000 volts. Clark cells will be compared with a number of standards, the E.M.F. of which will be determined from time to time. Instruments of different kinds from those mentioned will be tested as far as circumstances will permit. All enquiries on the subject should be addressed to Prof. Arthur Schuster, Owens College, Manchester, and headed "Physical Laboratory Testing Department."

Digitized by Google

Wator Power in India.—Some time ago a committee consisting of Profs. W. C. Roberts-Austen, W. C. Unwin, and G. Forbes, and Colonel J. Pennycuick, was appointed to consider the question of the utilisation of the water power derived from the Periyar Irrigation Works. This committee is reported to have concluded its investigations and issued its report. The committee is of opinion that by the adoption of the arrangements proposed, motive power can be supplied in the towns of Madras, Madura, and Trichinopoly at an annual cost of £3, £2, and £1. 10s. per horse-power respectively. Colonel Pennycuick deals with the hydraulic machinery. His calculations lead to the result that at the works the capital cost per horse-power would not exceed £4, or the annual charge about 10s. per horse-power. The motors, according to Prof. Unwin, should be either Girard turbines, as used at Turin, or tangent wheels. Prof. Forbes, in his report, deals with the cost of the electrical part of the works, including the generation of electric current and its transmission to certain points. He decides in favour of an alternating current. For general purposes he prefers the two-phase system, and bases his calculations on that. He suggests that the type of machine required is that each motor should be 5,000 h.p. Prof. Roberts-Austen deals with the question as to whether it is possible to obtain aluminium by electrical energy, and here it is only a question of the material whence the aluminium is to be extracted.

Electricity on Warships.—The Brazilian cruiser "Nictheroy," to which reference was made in a previous issue, is fitted with a complete electrical equipment. The plant consists of two 10in. × 10in. 50-h.p. Ideal engines, each belted to a standard General Electric compound-wound bipolar dynamo of 30 kilowatts, or 540 16-c.p. lamps capacity each. Upon a slate switchboard near the dynamos are mounted a full complement of marine volt and ammeters, and a double-pole knife switch for each circuit leaving the board. There are five circuits for the 300 incandescent lamps installed, two for the search-lights, and one for the 50-h.p. motor. The switchboard is so arranged that either dynamo can be used either on the motor or lighting circuits. The wires from the board are led through a special moulding, and wherever exposed to moisture are provided with a leaden armour. All the appliances such as switches, receptacles, etc., are of the same watertight pattern as used on the United States war vessels, as are also the fixtures, portable lights, deck and battle lanterns. For the last a separate circuit has been provided. They can thus be carried from place to place, and connected at different convenient points. On the roof of the pilot-house, says the New York *Electrical Engineer*, is set the automatic 30in. search-light, similar in size and intensity to that on Mount Washington, which throws a beam of light which can be seen from Portland, Me., 85 miles away. That on the "Nictheroy" is flanked on both sides by Hotchkiss rapid-firing machine guns, and can project a beam of light from its spherical concave mirror sufficiently powerful to allow light-coloured objects to be easily distinguished at 6,000 yards. It is furnished with a diverging lens, by which the beam can be diverged horizontally to cover a wide space. The lamp takes a current of 100 amperes to produce an effective arc between the points of the two, one and a quarter inch carbons. In the pilot-house is a small switchboard from which the search-light is electrically controlled, and may be moved in any direction horizontally or vertically. The small motors which do this work are concealed in the iron pedestal of the projector. The after search-light is used as an auxiliary. It is of the same pattern, but has a mirror of only 12in., and is hand controlled. The "Britannia" is also fitted with one 24in. and one 12in. projector. A 50-h.p. motor is used to train the dynamite gun, which can be raised, lowered, or turned to left or right as required. A system of electric signals completes the electrical equipment.

The Late Prof. Hertz.—The death has recently occurred of Prof. Heinrich Hertz, who was born at Hamburg in 1857. He studied physics at Munich, and afterwards at Berlin under Prof. Helmholtz. He then took up his abode as a lecturer at Kiel, and two years later was made professor at the Technical College of Karlsruhe, where his world-renowned experiments were instituted. Hertz's investigations deal exclusively with the relations between light and electricity. Maxwell had handled the subject theoretically, and already in 1865 had developed his electromagnetic theory of light. In connection with this enquiry, it now became a question of measuring directly, by means of experiments, the rapidity of the transmission of electric action; for instance, the charging of a Leyden jar or the motion of a magnet. Hertz was able to prove experimentally that electric waves, like light-waves, are transverse to the line of motion of the wave, and that they require a specific time for their transmission. Further experiments, in which the primary and secondary conductors were placed in the foci of two concave mirrors, showed that the electric waves followed the ordinary law of reflection. By the interpolation of a conducting screen in the path of the rays an electric separator was produced; the rays were not destroyed, but were reflected. Hertz was able to show the phenomena of refraction by the help of large prisms of asphalte or pitch. His experiments proved that there existed, not only optical waves of electricity of the well-known minuteness of waves of light, but similar ones measuring several metres, or even kilometres, in length. They proved that electric waves may be generated in connection with light-waves—that is to say, in innumerable places where their existence had hitherto been unsuspected. It goes without saying that the experimental proof of the intimate relation between light and electricity did not fail to win signal fame for its discoverer throughout the length and breadth of the scientific world. From a position of relative obscurity, Hertz leaped at a single bound to world-wide celebrity. His call, as the successor of Clausius, to the chair of physical science at Bonn, followed in 1889, an appointment which was of short duration. The Royal Society in 1890 awarded to Prof. Hertz the Rumford medal for his discoveries in connection with electromagnetic radiation.

The Midland Institute Exhibition.—The small exhibition at Birmingham, of which a description was given last week, was really very interesting and highly creditable to its organisers, and it may well serve as an example to those who are interested in the supply of electricity in other places. It was neither a purely scientific display nor a bazaar for display of goods seeking customers, but an attempt to educate the general popular mind and impress upon the visitors the practical uses which they could make of the electric current as now supplied from the mains, involving only the periodical operation of paying for the work done for them. The mode in which the current is led into the houses in Birmingham was shown in an actual connection through which passed the current working the exhibits. The meters as used were shown with their working parts exposed, and in the case of the Ferranti with a complete set of the parts separately. Two small rooms were so fitted as to tend towards a breach of the tenth commandment, who might covet without being able to obtain such pleasant surroundings. A rigidly correct follower of Ruskin might object that the true canons of art

Digitized by Google

would not permit lights to issue from wine-decanters, pretty enough in themselves to be more agreeably occupied, but the graceful cut and ground glass chandelier in one room was equalled in beauty by the contrasted yellow and white glass of that in the other room, each of them being well brought out by their surroundings, and exhibiting all the virtues of the electric light. A number of motors were working smoothly at various operations adapted to exhibit their utility. The most notable were a dentist's drill, so perfectly under control that it suggested that even the aching void of a hollow tooth might give pleasure to a properly-balanced scientific mind—perhaps more perfectly if in someone else's head. But the neatest illustration, and one which caught the attention of the lady visitors, was a sewing-machine perfectly controlled by the pressure of the foot on the ordinary treadle; this moved a lever carrying the motor and tightening or slackening the driving cord, and at the same time actuating a brake which stops the motion of the machine. There was a great display of cooking apparatus, and illustrations of cooking without dirt and smoke, baking, and heating irons at any desired temperature, and saucepans boiling merrily away by heat contained in their bases. No doubt this display must have been very interesting to many visitors, and let us hope that some among them may be inclined to taste and try the results under their own supervision. There were, of course, plenty of illustrations of electric lighting and its management of interest to the visitors.

Electricity in Mining Operations.—A lecture on this subject was delivered on Saturday at Derby by Mr. George Fletcher, under the joint auspices of the Midland Counties' Branch of the National Association of Colliery Managers and the Technical Education Committees of the Nottinghamshire and Derbyshire County Councils. Mr. Fletcher dealt with the subject under the heads of the application of electricity to signalling, blasting, lighting, the transmission of power, pumping, hauling, and coal-cutting, and also testing for gas. After explaining how electric currents can be generated, he passed on to a consideration of transmission and utilisation of electrical energy. The lecturer then referred to pumping and hauling appliances in operation at St. John's Colliery, Normanton, and at the Abercanaid Colliery, and by the kindness of Mr. Howell he was able to lay before his hearers photographs of the plant and curves showing the efficiency of the plant. Referring to its application to mining, he pointed out that where there was any surplus power the electric lighting was certainly economical. Experiments had been tried with a view to substituting the ordinary miners' lamps by electric lamps attached to the electric mains by flexible conductors. That had, however, proved inconvenient, and what was wanted was a portable electric lamp. Many such lamps were on the market, but he was not aware that any one of them complied with the requirements. Those requirements were, he understood, low first cost, that the lamp should not be more than 4in. square, or 3lb. or 4lb. in weight, that it should maintain a light of about 1 c.p. for 14 hours at a cost of about 1d., and that it should not easily get out of order. As to its superior safety, it should not be forgotten that it lacked the advantage of being a ready means for detecting the presence of fire-damp, and it was by no means certain that the fracture of an electric lamp would not lead to an explosion if it were surrounded by an explosive mixture. True, many lamps had been broken in an explosive atmosphere without producing an explosion, but by means of experiments it had been found that explosions did sometimes result. Undoubtedly there were means of rendering it impossible for the fracture of the glass to fire explosive mixtures. In regard to its use in testing for gas, he explained that it had long ago been found that a thin platinum wire which was made to glow by the passage of an electrical current through it, increased in brilliancy when placed in an atmosphere containing a small percentage of fire-damp. That fact had been made use of in gas indicators, and it was generally admitted that this was a very delicate means of testing for gas, but that it was exceedingly inconvenient to use, and that in a great measure had prevented its adoption. The lecturer had, however, devised and provisionally protected an invention for a more convenient application of this process. In conclusion, Mr. Fletcher referred to the use of electricity for coal-cutting.

Driving Printing Machinery by Electric Motors. A noteworthy example, which we trust will soon be followed in many other cases, has just been set by the proprietor of the *Pall Mall Gazette*, who is the first in the Metropolis to introduce electric motors for driving printing machinery for the production of newspapers. There are already two or three towns in the provinces where electricity as a motive power is used in newspaper offices, but until now London has remained behind in this direction. The plant at the *Pall Mall Gazette* offices, put in operation for the first time on Tuesday, was supplied and designed by Messrs. Mather and Platt, Limited, under the superintendence of their engineer, Mr. Hardman A. Earle, M.I.E.E. It consists of two 40-h.p. motors of the Manchester type, driven off the outside mains of the Charing Cross and Strand Electricity Supply Company's three-wire system. This gives a constant pressure at the terminals of the machines of 200 volts. The motors are connected by belts to a common 4in. countershaft, divided into three sections so as to avoid the use of fast and loose pulleys. By means of handwheels, actuating a couple of clutches, either or both motors can be turned on to the countershaft at will, and made to act on the main shafting of the presses, which passes through a channel underground. The current supplied to the motors being taken from the electric lighting mains, special arrangements had to be made by Mr. W. H. Patchell, A.M.I.C.E., M.I.E.E., the chief engineer to the supply company, to prevent the load all coming on at once; and for this reason a set of resistances in parallel is placed in the circuit to each motor, so that by simply moving a lever on from one contact to another slowly, the current is supplied to the motor by degrees, allowing the engineer at the central station to make any adjustment that may be necessary to prevent fluctuations in his light. The working of the printing-presses in the production of an evening newspaper takes place, fortunately, during the daytime, before the demand for electric lighting upon the central station has reached an appreciable amount. The larger a central station is, or, rather, the more lamps it has upon its circuits, the less necessary this adjustment becomes. Half a minute is, therefore, devoted to turning the current on gradually, and when the motor has once attained its speed no alterations in the load will perceptibly affect it. Before the plant was brought into use a large portion of one day was devoted to making careful tests of the electrical and mechanical efficiency of the new plant. The belts were all coupled up to the shafting, the clutches fixed, and then one motor was started from the company's mains. This drove the countershafting round (but not the main shafting, which was disconnected), and caused the other motor to revolve as a dynamo. The current from this was then passed into a battery, and the energy it represented was carefully compared with that put into the motor from the company's mains. The results were announced to be highly satisfactory.

PRACTICAL INSTRUMENTS FOR THE MEASUREMENT OF ELECTRICITY.

BY J. T. NIBLETT AND J. T. EWEN, B.SC.

XVI.

(Continued from page 535, Vol. XII.)

RESISTANCE, *continued.*

Jenkin's Resistance-Measurer.—Another modification of the differential galvanometer method of measuring resistances is due to the late Prof. Fleeming Jenkin. Instead of the coils being set parallel to each other, as in the Siemens instrument, they are mounted with their centres coincident and their axes at right angles, so that in plan view they form a cross, as shown in Fig. 40. They are so mounted as to be capable of rotation about their common vertical diameter, and at their centre is suspended a short magnetic needle, to which is rigidly attached a long light pointer. The position into which the coils have been turned may either be indicated on a circular scale by means of an index which turns with them, or some such arrangement as that shown in Fig. 40 may be

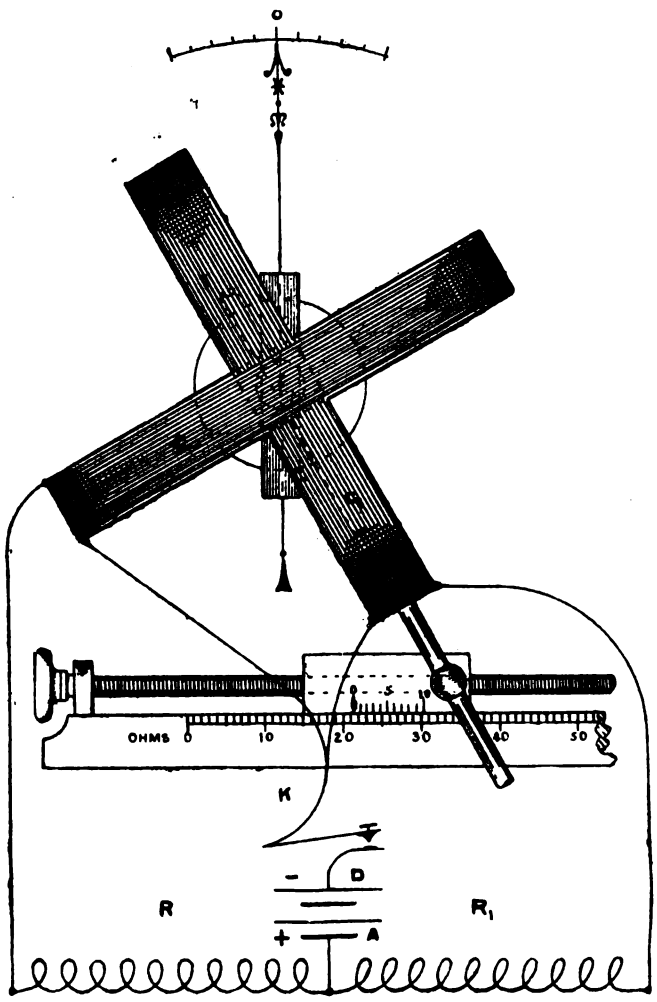

FIG. 40.—Jenkin's Resistance-Measurer. Diagrammatic Plan View.

adopted. As will be seen from Fig. 40, which shows a diagrammatic plan view of the whole apparatus and connections, the connections to the battery, the key, and the two resistances are made in precisely the same way as in the Siemens instrument; and the two portions of the current passing through the two coils tend to turn the needle in opposite directions just as before.

There are various ways of getting over the practical difficulties of arranging the two coils of this instrument. In one method the two cores on which the coils are to be wound are made of the same size, and rigidly fixed together so as to intersect each other; the two wires are then wound in alternate layers, so that the two coils when completed have their wires interwoven at the crossings. Another method is to make the one coil so much smaller than the other as to be just able to pass through it, and to wind the two in such a manner that with equal currents the magnetic effects on a needle suspended in the usual way at their common centre will be exactly the same. The coils are then mounted, as before, on a vertical axis, the two coils being at right angles to each other and the one inside the other.

A third, and perhaps the best, of the three methods is to make the two coils exactly equal and similar in every way, and to mount them at right angles to each other on the same vertical axis, and the one on top of the other. A pair of needles are required in this case, one for each coil. These are made exactly the same, and are magnetised to precisely equal extents, and are then placed parallel to each other and attached rigidly to the ends of a stiff metal wire, equal in length to the distance between the centres of the two coils. Thus, when this arrangement is hung in position by means of the usual silk-fibre suspension, we have two horizontal needles—one suspended at the centre of each of the two coils—swinging in unison, so that the same vertical plane always passes through their directions. The magnetic moments in this case are, of course, exactly the same as if the two coils had been made to intersect each other, and had a single needle suspended at their centre, as in the first case; and by this arrangement several difficulties in construction inherent in both of the other methods are overcome.

The device illustrated in Fig. 40 for rotating the coils and indicating the position into which they have been turned to obtain "no deflection" of the needle on sending the currents through the coils, enables the value of the unknown resistance, R, to be read off directly in ohms from a suitably graduated linear scale, just as in the Siemens instrument.

The motion of the two crossed coils, C and C_1, about the vertical spindle, round which they are free to turn, is controlled by means of the long screw which is rotated by the milled head shown at the left side of the diagram. On this screw rides a block, through a guide on which passes a long rod which turns the coils about their vertical axis. This rod is always kept in the same vertical plane as the coil C_1 by means of two guides fixed beneath the coil. As is indicated in Fig. 40, the screw, the main scale, and this directing-rod are all made much longer than shown, in order to permit

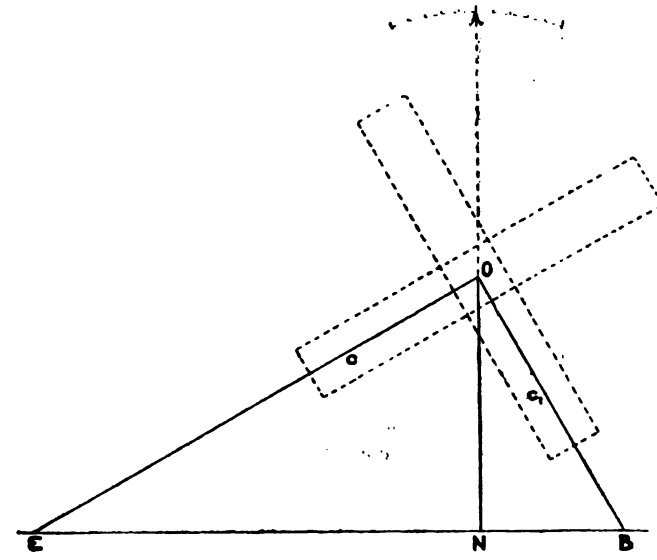

FIG. 41.—Skeleton of Jenkin's Resistance-Measurer.

of the coil C being brought round so as to be nearly perpendicular to the direction of the scale.

The value of the resistance R being measured is read off directly from the linear scale by means of the vernier engraved on the sliding block as shown.

The principle on which this depends may be explained in the following manner. Suppose that the known and unknown resistances, R_1 and R, are connected up along with the battery, A D, and the key, K, to the two coils, C and C_1, as shown in Fig. 40, and that the vernier has been adjusted to such a position, by means of the milled head and screw, that the needle pointer shows no deflection when the key is closed.

Let O in Fig. 41 represent the common axis of the two coils, and E B a line drawn parallel to the linear scale through the guide on the vernier block. Let O E and O B represent the directions of the two coils, C and C_1, respectively (B repre-

Digitized by Google

senting the guide on the vernier block), and let O N be drawn perpendicular to E B.

Now since the needle is not deflected when the circuit is closed, the magnetic effects of the two opposing currents in the coils, C and C_1, must be exactly equal; and, therefore (according to the principle of the ordinary galvanometer), the currents in the coils are proportioned to the sines of the respective angles between the coils and the needle. But (on the principle of the Wheatstone bridge) the currents themselves are inversely proportional to the resistances of their respective circuits.

Thus we may write

$$\frac{\text{Resistance of R + C}}{\text{Resistance of } R_1 + C_1} = \frac{\text{Current in } C_1}{\text{Current in C}} = \frac{\text{Sin B O N}}{\text{Sin E O N}} = \frac{\text{Sin B O N}}{\text{Sin O B N}} = \frac{\text{N B}}{\text{N O}};$$

or to write this in another way,

$$\frac{\text{Resistance of R + C}}{\text{N B}} = \frac{\text{Resistance of } R_1 + C_1}{\text{N O}}.$$

But whatever the position of the coils, the distance N O is always the same, and the value of the resistance $R_1 + C_1$ is also constant and known. Therefore, from the above relation it is evident that on the same scale on which the distance N O represents the resistance $R_1 + C_1$, the resistance of R + C is similarly represented by N B. Thus, equal increments in the resistance of R + C are represented by equal increments of the distance N B; and the magnitude and value of the divisions on the linear scale are readily obtained from the above proportional relations. Further, since the resistance of the coil C is a fixed and known quantity, the position of the vernier zero can be so adjusted on the sliding block that it deducts the resistance of C from the length N B on the scale, and reads off the value of the resistance R in ohms direct. In the example shown in Fig. 40 the value of R is 21·2 ohms.

(To be continued.)

FAULTS IN DYNAMOS.

(Continued from page 43.)

D. Open Circuit in the Internal or External Circuit.—When the fault is in the external circuit, an incandescent lamp inserted between the terminals of the dynamo after the main leads have been removed will burn steadily; otherwise, the fault must be looked for in the internal circuit in the manner following:

(*a*) *Disconnection in the Field Coils.* — By means of a battery and galvanometer or bell connected as in Fig. 1 this fault can be readily detected, care being taken to first detach the ends of each coil. A disconnected coil will not cause any deflection of the galvanometer or sound of the bell. After each coil has been tested, all the connections in circuit should be carefully examined and the contacts scrupulously cleaned.

(*b*) *Disconnection in the Armature Circuit.*—To determine whether a break exists in the armature circuit, the wires connecting the coils with the collector should first be removed and each coil tested with the apparatus as in Fig. 1. If with one of the coils tested in this way there is no deflection of the galvanometer, there is a want of continuity, which should be tested for as follows: The dynamo should be started, and two points, *c d*, of the commutator, Fig. 4, comprising between them several bars, should be touched with a wire, *a b*. If the machine begins to give current a spark will show on the commutator between the two ends of the wire, *a b*, and thus indicate that the fault is between those two points. If no sparking occurs, other points of the commutator must be touched with the wire, *a b*, until sparking does occur. Immediately a spark shows, however, the dynamo must be stopped to avoid damage to the commutator and armature. The faulty coil can then be detected by the traces of burning which will appear upon the bar corresponding to it. In the majority of cases this fault is more often due to a bad contact than to rupture of the conductor, and it has a very mischievous effect upon certain bars of the commutator by reason of the strong sparks which are produced when the brushes pass over those bars. It is necessary, therefore, whenever the bars wear unequally to test all the connections between them and the coils corresponding to them, so that the fault or faults may be detected and repaired.

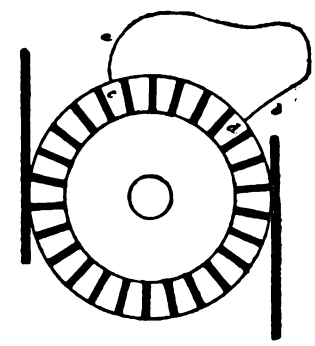

Fig. 4.

(*c*) *Brush Not Making Contact.*—A simple examination of the brushes is sufficient to show this defect.

(*d*) *Disconnection in the External Circuit.*—When the test described under D shows that the fault is in the external circuit, examination must be made of all the apparatus in circuit—terminals, cut-outs, lamps, etc.—to see if they are in good order, or making good contact, as the case may be. This examination (made, if possible, with a battery and galvanometer) should include the switchboard, etc., and if it does not indicate the locality of the fault, all the apparatus should be left open, and the main leads, tested with a battery and galvanometer, joined up as in Fig. 5. One of the poles of the battery and one of the ends of the lead to be tested are put to earth, and the other end of the lead is touched with the wire *f*. If the lead is not broken, the galvanometer needle will deflect, and *vice versâ*. To locate the fault, the wire *f* should be connected with *n*, and a section of the lead tested by connecting it, for instance, at *p* with the wire *f'*. If there is then a deflection, the part *n p* is in good order, and the fault must be looked for between *p* and *q*. The wire *f* can then be joined at *r* to see if the fault is between *r* and *p*, and thus by making repeated tests the fault may be located in a section sufficiently short to permit of its being discovered on examination. In an installation where the lamps, etc., are mounted in parallel on the main leads, the working of the dynamo cannot be interfered with except by a break in the main circuit, because if any interruption occurs in a branch the lamp or lamps on it would go out, but the rest of the installation would continue to work.

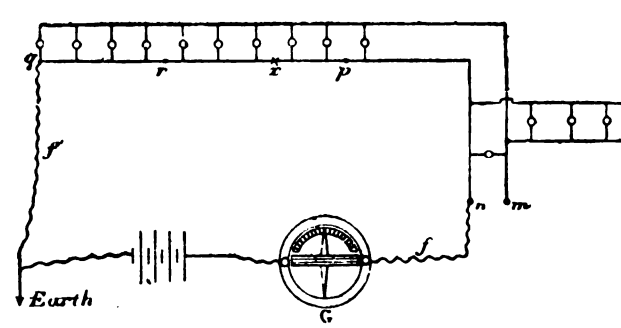

Fig. 5.

E. Reversed Field-Magnet Coils.—When the field-magnet coils have been placed on their cores in the reverse way, or their connections have been reversed, strong magnetisation of the pole-pieces will be perceived on approaching to each of them in turn a small piece of iron. If the experiment is made with a suspended magnet, each of the pole-pieces will attract the same pole of that magnet, indicating that they are of the same instead of being of opposite polarity. When the dynamo is of the multipolar type, the experiment must be made with two consecutive pole-pieces. Once the fault is detected, it may

Digitized by Google

be remedied by rewinding the defective coil or reversing its connections.

II. PRODUCTION OF STRONG SPARKS AT THE BRUSHES.

Causes of serious sparking at the brushes are:

A. Surcharge from the dynamo. (a) Excessive voltage. (b) Great excess of current. (c) Bad insulation of the external circuit.
B. Bad adjustment of the brushes.
C. Bad state of the commutator.
D. Bad state of the brushes or brush-holders.
E. Disconnection in the armature circuit.
F. Short-circuit in the armature.
G. Defective insulation of an armature coil.
H. Weak magnetic field.

A. SURCHARGE FROM THE DYNAMO.—When the dynamo is surcharged—that is to say, when the voltage or the current is excessive—not only will violent sparking be produced at the brushes, but the field coils and the armature will be greatly heated (see III.); otherwise the belting is much too tight, and will make a noise as it slips on the pulley.

(*a*) *Excessive Voltage.*—This fault will be shown by the voltmeter. It may be due to either excessive excitation or excessive speed. In the one case the resistance should be increased to diminish excitation, as this frequently rectifies the voltage, and in the other case—which can be ascertained with a speed indicator—the engine driving the dynamo must be reduced in speed. It may also happen, when a dynamo is started for the first time, that the excess of speed is due to the pulley being of improper size.

(*b*) *Great Excess of Current.*—When a dynamo is supplying arc lamps, the surcharge may have its origin in an excess of current. The ampere-meter will show this, and the resistance in the circuit of each arc lamp can be increased until the fault disappears. If incandescent lamps are in circuit, the fault may be occasioned by there being more lamps than the dynamo is able to supply. In that event, lamps should be cut out until the defect is remedied.

(*c*) *Bad Insulation of the External Circuit.*—It is also possible that the surcharge may be due to bad insulation of the external circuit, giving rise to a considerable increase in the current furnished by the dynamo. This often occurs in rainy weather, when the external circuit is aerially carried and consists of naked wires. To locate the fault or earth contact, the main leads should be removed from the terminals of the dynamo, and the ends, *m n*, left open.

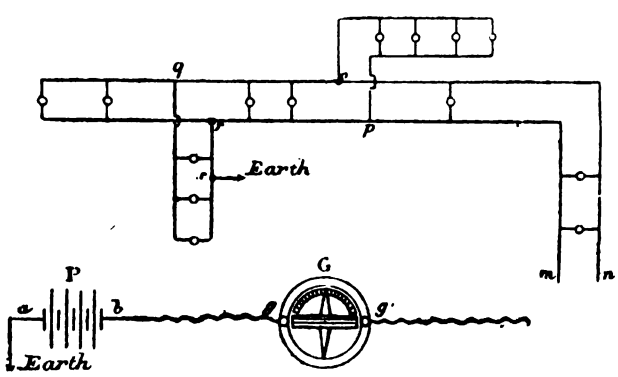

FIG. 6.

That done, the lamp circuits should be closed, as in Fig. 6, and one pole, *a*, of a battery, P, put to earth through a gas or water pipe, and the other pole, *b*, connected to one terminal, *g*, of a galvanometer, G; attaching to the terminal *g'* a wire for a purpose about to be explained. Suppose there is a loss to earth at a point, *x*, of the line or wiring. The end of one of the main leads—*m*, for example—is touched with the wire from *g'*. If there is no earth contact, the needle will not be deflected, but if there is, it will be deflected. To localise the fault, the leads should be disconnected from the branches, *o p* and *q r*, and then the lead, *m* or *n*, should be again touched with the wire from *g'*. If there is no deflection, the fault is not in the main circuit, and the branches, *o p* and *q r*, should be connected one at a time and tested as before. One of them will be faulty, and as soon as it is known which one it is, all the lamps and apparatus in that branch should be opened, and the wires *q* and *r* tested separately. Then, if a close scrutiny is made of the defective wire, the fault should be easily found. It often happens that the shunt circuits are faulty, and in such case it is necessary to disconnect them from the main leads for testing purposes.

B. BAD ADJUSTMENT OF THE BRUSHES.—When sparking is caused by bad adjustment of the brushes, it may be ascertained by displacing or shifting the brush-holders, for the reason that the sparking will vary with each movement. To obtain good adjustment, it will be sufficient to move the brushes gently backwards and forwards until a position is found in which the sparking is reduced to a minimum. If that does not have the desired effect, see whether the contacts of the opposing brushes are of exactly the same diameter, because if the brushes are not precisely in opposition they should be readjusted. A simple means of discovering this is to count the bars of the commutator, or take a measurement on each side of the space which separates the brushes from each other. If, for instance, a commutator is composed of 40 bars, and that upon which the upper brush is placed be called No. 1, the lower brush to be in its proper position should be on the twenty-first bar. Correct position of the brushes is a matter of great importance, and they should make gentle but firm contact with the collector. If they press too heavily, they soon wear out; if too lightly, they are liable to jump and produce sparking. Care should be taken that none of the wires or laminæ of the brushes are turned up out of the flat, but that they all lie evenly upon the collector, and that they and the brush-holders are thoroughly well made and fitted. The points of contact of the brushes with the collector should always be those which give rise to the minimum of sparking. At the same time, it should be remarked that these points will vary with the strength of the current.

C. BAD STATE OF THE COMMUTATOR.—This, again, produces excessive sparking. To find if the fault arises from this cause, see if the commutator turns freely, is quite round, and has no inequalities of any kind on its surface, as the latter will prevent the brushes from making good contact. To determine whether the commutator is quite round, it should be turned gently and closely examined. If not quite round, it should be made so in a lathe, either with or, when possible, without removal of the armature. Inequalities on the surface of the commutator may be small scratches caused by sparking, or be due to displacement of the bars. If the commutator is gently revolved, these inequalities may be felt with the hand, but if it is a high-tension machine, a small piece of wood had better be used. If scratches, etc., exist, they should be rubbed down with sand-paper, but emery-paper must on no account be substituted. If sand-paper is not sufficient, a file in the hands of a competent workman may be employed, but the metallic dust must be carefully removed to avoid short-circuiting the armature coils. In case the inequalities are due to wearing, from friction with the brushes, the lathe must be resorted to.

D. BAD STATE OF THE BRUSHES AND BRUSH-HOLDERS.—If these are in a defective condition, there will be bad contact between the brushes and commutators, and consequently much sparking. To ascertain this, proceed as in B, and remedy the fault by readjustment and cleaning.

(To be continued.)

INSTITUTION OF ELECTRICAL ENGINEERS.

INAUGURAL ADDRESS OF MR. ALEXANDER SIEMENS, M.I.C.E. (PRESIDENT).

(Concluded from page 47.)

Originally the steam-dynamos were designed for use on board ship, where economy of space is of importance, and great credit is due to the Admiralty for introducing very early a system of testing which has been no small incentive to all concerned to improve the dynamos as well as the steam-engines. In these tests the dynamo is run for a number of hours at its maximum output, and no part of it

Digitized by Google

must get hotter than the surrounding air by more than a prescribed number of degrees of heat. Nothing could be simpler than this test, and at the same time it is the most reliable way of finding out whether a dynamo has been constructed suitably for its work. During the same run the water is measured which, in the form of steam, is supplied to the engine, and the relation between the water consumed and the electrical energy supplied to the electrical circuits determines the merit of the steam-dynamo tested.

By far the most important connection between mechanical and electrical engineering is, however, the transmission of power, which has of late acquired so much prominence. If the first stage of the development of the electrical industry was closely connected with telegraphy, the second step may be said to have been taken when electric lighting was introduced, and now it seems that transmission of power is the problem which electrical engineers have to grapple with in the near future. The success of electric tram lines has undoubtedly contributed to direct general attention to the transmission of power by means of electricity, but great care will have to be exercised so as not to start in a direction that can lead to no practical results. Many schemes have been started to introduce electricity as the motive power on the main lines of railway, and to accelerate at the same time the speed of the trains very considerably, even up to 200 miles per hour. It would be rash to say that such a speed will not be attained some day, but in my opinion none of these schemes can be carried out on a commercial basis with the means at present at our disposal. Trebling the speed of the trains necessitates a radical alteration in the laying of the permanent way, a thorough reconstruction of the carriages, and demands an amount of power that we have no means at present of estimating accurately, nor have we motors that could produce it with a moderate weight. Even if these obstacles are overcome, the enormous capital outlay could only be justified if a very frequent service was kept up, as in the case of successful electric tramways. In most schemes it is, in fact, proposed to run single carriages at short intervals between important towns, but up till the present time it has not been possible to convince capitalists that such a service would pay, either between Vienna and Budapest, or between Chicago and St. Louis, which are the most notable instances of such schemes.

Leaving these ambitious projects out of consideration, enough scope remains for the development of electric traction in this country to render a healthy activity in this branch of our industry probable for a number of years; and the report of the Hybrid Committee which sat last year has removed, let us hope, a very serious obstacle to electric traction. As the rules which the Board of Trade has drawn up in accordance with the instructions of this committee are still under consideration, it would obviously not be in order to criticise the version that has been published; it would, however, be hampering the industry if too many details were too accurately prescribed. In this connection it must not be forgotten that in the past the industries of this country have been developed, to the great advantage of the nation, with very little legislative interference; and it would at present be premature to make the regulations about electric traction too stringent, as the working out of this branch of electrical engineering is by no means completed.

Besides traction, there is the distribution of power, in which mechanical engineering is of the greatest influence on the successful application of electricity. It is, of course, a purely electrical problem to deliver your current either at a standard voltage, or in a constant quantity, at all points of your network of mains; but the application of the motors to the work they are required to do, and the determination of their dimensions, involve principally mechanical considerations. How much there is still to be done in this respect was made apparent during the discussion of Prof. Forbes's paper on the proposed utilisation of water power at the Niagara Falls. Although the prevailing opinion seemed to be that for transmission to a great distance alternate currents only can be utilised, I believe that of the actually established long-distance transmissions the greater part are worked with continuous currents. No hard-and-fast rule can apparently be laid down that either the continuous or the alternate current should be preferred in all cases where power has to be transmitted to a distance; and in judging of the merits of the two systems the proper conclusion can only be arrived at if the commercial aspect of the case is allowed to decide the question.

The installation of rotary-current motors at the Frankfort Exhibition driven by the water power at Lauffen was undoubtedly an engineering success, and served very well for the purposes of an exhibition; but nobody has attempted to do everyday work on the same lines, for the simple reason that it would have been much cheaper to produce the power in Frankfort by steam-engines than pay the commercial interest on the outlay that had been necessary to establish the transmission from Lauffen. The generating plant of this installation is now used for the lighting of Heilbronn, and there are a few other instances where rotary currents are used for long-distance transmissions; but, as I said just now, it would be wrong to generalise by preferring either the one or the other method of transmission in all cases.

Another great field for electric motors is just being opened by their introduction for distributing power in works, with a view of abolishing shafting, leather belts, and other intermediate gearing, and of giving each lathe or other tool an independence that cannot be attained under the present system. A most interesting paper on this subject was read by M. Castermans before the Society of Engineers in Liège in August, 1892, in which he compares in detail several proposals for distributing power in a new small-arms factory that has since been erected at Herstals. The result he arrived at was that with electrical motors he could exert on the working machines 70 per cent. of the power generated by the main engine, while the next best other method gave only 63 per cent., when the shops were working at their full capacity.

In these problems, again, mechanical engineering questions decide whether the application of electricity is justifiable; and it is quite apparent that an electrical engineer requires to be well versed in a variety of subjects if he wishes to keep in the front rank. Fortunately for our profession, the question of technical education generally has received particular attention during the last quarter of a century; and omitting all reference to other occasions when this subject has been brought before this Institution, I will only remind you of the eloquent address of Prof. Ayrton, which no doubt is still fresh in your memory. It will, therefore, not be necessary for me to repeat his lucid exposition of the transition from the former system of pupilage to the modern one of educating the budding engineers in colleges and their laboratories, which has supplemented, and to a great extent supplanted, the old one. No doubt this altered system of education is capable of producing a class of men who are well adapted to explore the untrodden fields of applied electrical energy, where the problems constantly demand a thorough knowledge of scientific principles; but, in combination with this, an equally entensive acquaintance with practical possibilities is requisite. This most important co-operation of science and practice is essential for all real success, and no doubt it appears to be superfluous to insist on the necessity of bearing this in mind; but a perusal of patent specifications will at once convince you that either the one or the other factor is sadly wanting in many would-be inventors. Years ago it was science that was most conspicuous by its absence in these documents; but in the present time it is very often obvious that the inventor has no clear conception how his invention could be carried out so as to make it useful to mankind, and even fails to see the obvious impossibility of realising his ideas in the way he claims in the specification. As usual, it is very difficult to steer the middle course; and if the scientific man had for years to cry in the wilderness because his pursuits did not receive the proper attention in the education of engineers, it seems now to be the turn of the practical man to warn students that there is something more to be learned besides scientific truths before they can aspire to be recognised as engineers.

It has always appeared to me that at school the mental

Digitized by Google

powers should be principally exercised in a way to make them fit for learning, and that at the same time they should become accustomed to the careful consideration of a problem in its various aspects. Although it has been the fashion of late to deprecate the study of Latin and Greek, I am quite certain that the attack is made from quarters where the mental training which the study of these languages entails is not appreciated at its right value, nor is the enormous advantage considered which their knowledge gives in the study of modern languages. After the mental powers have been prepared in this way, it is of no great consequence whether most of the details of the school teaching are speedily forgotten or not; the essential point is that the student should have acquired a good method of learning, so as to assimilate to the best advantage the course of training he attends at college. While the teaching at school has a general character, and embraces chiefly subjects that ought to be known to all classes, at college the various professions are differentiated, and in each branch the students learn the general principles that ought to govern them in their future career.

Formerly it was possible to let the course of scientific studies embrace all that was known in any particular branch; in fact, the general principles and the interdependence of the various branches were not, and partly are not yet, properly understood. To attempt a similar course at the present time is simply impossible, and the danger that has to be avoided in our scientific colleges is the tendency to teach our profession too much in detail. Besides overwhelming the professors with work, such a course is apt to create in the students the conviction that on leaving college with a first-class certificate they know all that can possibly be known, and that anything that does not fit in with the theory of their pet professor must necessarily be condemned.

A fault into which young men are liable to fall, when they come full of honours from college, is that they consider the passing through workshops beneath their dignity, especially when they have attended for the prescribed time in the workshop of the college. They quite forget that the practical conditions that prevail in works where machinery is made for sale differ entirely from those of a laboratory, where the only aim is to give the students an opportunity of acquiring manual skill. Another class of students commences practical work with the greatest interest, and the fixed determination to introduce with all possible speed the various improvements which the difference of the practical work with which they come in contact from the teaching at college suggests to them. On all these students it cannot be impressed too much that the practical training is of quite as much importance as the scientific course at college; in fact, in most cases the conclusions of pure science have to be modified by practical considerations before a useful application of science can be produced.

For this reason it is highly desirable that the teaching at engineering colleges should be confined to general principles as far as the applications of science are concerned, but that the students should become thoroughly well acquainted with the mental tools that are used in scientific investigations, such as mathematics, the general principles of chemistry, and of the branches of natural philosophy. While the student is trained afterwards in practical work, he has time to select what special branch of the profession he wishes to devote his life to, and no doubt he will find that his college studies have to be supplemented by reading up the various technical works referring more particularly to the selected branch. If he has been able to acquire a certain knowledge of modern languages, he will find his labours lightened very materially by having a much larger range of literature to select from.

In this respect electrical engineering has been especially fortunate, for it has more than any other profession an international character, and this Institution has from the very commencement counted among its members distinguished electrical engineers of many nationalities. It is quite true that after a time the principal foreign nations formed their own electrical institutions, but the international character of the profession has been kept up by the congresses which have met from time to time with a view of regulating electrical matters of international importance. At the official congress which met last year at Chicago, an international system of units of measurement has been settled, or, rather, readjusted, for the electrical engineers have from the beginning enjoyed the immense advantage that their units of measurement have been the same in all countries. Not only has this circumstance greatly promoted the intercommunication between the various nations, but the character of the electrical units facilitates the demonstration of the interdependence of the various forms of energy, and simplifies the calculations of the engineering profession. If a proof were necessary of the utility of having the same units understood in all civilised countries, it is only necessary to observe the conditions and the tendencies that prevail in other matters of international interest.

It is chiefly owing to telegraphy that the conditions of modern life differ so essentially from the state of things before the means of quickly communicating with distant parts were at the service of the community at large. Through the ever-increasing network of telegraph wires all mankind is drawn together, and the mutual reaction of the affairs of distant nations is very well illustrated by the newspapers of all countries vying with each other to bring the latest news from all parts of our globe, and by the effect this news produces at home. Not only are industrial enterprises greatly aided by the possibility of watching their progress in distant countries as easily as it was formerly possible to follow the fortunes of works in the next county, but the distribution of the commodities of life can be regulated in such a way that an extraordinary demand in one country can be met by an extraordinary supply from another one. Under such conditions of intercommunication it is not to be wondered at that attempts have been made, and, in fact, have been to a great extent successful, for facilitating the intercourse between nations in various directions where an international agreement could do away with existing difficulties.

One of the most important international conventions is the Postal Union, into which most nations of our globe have entered, and whose influence is brought home to us every day. In another direction an effort has lately been made to make the mode of reckoning time more uniform, and the result is that Greenwich time has practically been adopted in a great many civilised countries by making the local time either the same, or differing from Greenwich by one hour or by multiples of an hour. An even more important agreement among many nations has existed now for more than a quarter of a century by their adopting the metrical system of measurement; and it is well worth while seriously to consider the effect of this concerted action on the part of foreign nations, as it forms an ever-increasing obstacle for the successful competition of English manufacturers. An ideal system of measurement should be based on units which can be reproduced at any time and at any place with mathematical precision, and you all know that the metrical system was intended to embody this desirable condition. From various causes, into which I need not enter here, the attempt has failed; even the kilogramme does not bear the relationship to the linear units which it originally was intended to have, so that the bases of the metrical system are now an arbitrary metre and an arbitrary kilogramme. All the same, its very general adoption has proved a very great convenience, and there is little doubt that the introduction of international electrical units has been accomplished with such facility because they are based on the metrical system.

When we recollect that it was a German professor who suggested the absolute system of measurement, that the British Association first established practical electrical units, that the metrical system is of French origin, and that the electrical system of measurement was elaborated by discussions between engineers and scientific men of all nations at the various congresses, we cannot wonder that a very perfect system has been the outcome, and that its general adoption in all countries has followed without discussion, although the formal recognition may not yet have been pronounced in all cases. Even in this system it has been found necessary to settle one of the units—the ohm—in an arbitrary manner, as it was recognised that for practical purposes it was better to have an arbitrary but fixed standard, than to correct the unit every time that

Digitized by Google

an improvement in methods or in instruments admitted of determining it with greater accuracy than before. It is well worth while to reflect on the lesson which this fact conveys—viz., that, in spite of the earnest endeavours and the painstaking collaboration of most competent men, it has not been possible to follow out in practice the dictates of pure science, but that a compromise was found to be inevitable.

The conclusions to which this consideration of the influences that have shaped the course of electrical engineering leads us, may well awake in us the hope of an ever-increasing activity and of an ever-growing importance of the applications of electricity; but we must not forget that we can only succeed if we understand how to adapt our work to practical requirements without losing sight of scientific laws. For this reason nothing can further the interests of our profession more than a free and frequent interchange of ideas between the engineers, who carry out the practical applications, and the scientific men, who investigate the nature of electricity.

In the past this Institution has been the arena in which many subjects have thus been discussed to the advantage of everybody concerned; and it is the duty of all its members to contribute, either by reading papers or by criticising those submitted by others, to the development and to the ever-increasing importance of the electrical engineers.

IMPEDANCE IN AERIAL LINES AND ALTERNATE CURRENTS.

M. Hospitalier, in an article in *L'Industrie Electrique*, considers the question as indicated by the following abstract:

The increase of effective resistance in a conductor of circular section to the passage of alternate current is not so important as the inductive phenomena. The formulæ given below permit the calculation of the impedance in aerial lines, and the determination of the increase of pressure required to overcome this impedance.

Let the aerial line be formed of two parallel wires of radius r, length l, the total length of the wires being $2\,l$, at a distance d, with a self-induction L, a resistance R, the wire having a resistivity ρ, all the quantities being measured in C.G.S. units. The impedance of this line for an alternate current of pulsation ω (calling pulsation, with Prof. Fleming, $2\,\pi$ times the frequency) will be equal to

$$\sqrt{R^2 + \omega^2 L^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

and supposing $\sqrt{R^2 + \omega^2 L^2} = k\,R$,

we have a relation which defines a new physical quantity, which Mr. Kennelly calls the "factor of impedance." This, by definition, is the factor by which the electric resistance has to be multiplied to obtain the impedance or apparent resistance.

In the particular case considered with a double aerial line of parallel copper wires of circular section, we have—

$$L = 2\,l\left(\frac{1}{2} + 2\,\log_e \frac{d}{r}\right) \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$R = \frac{\rho \cdot 2\,l}{s};$$

$$R^2 = \frac{4\,\rho^2\,l^2}{s^2} = \frac{4\,\rho^2\,l^2}{(\pi\,r^2)^2} = \frac{4\,\rho^2\,l^2}{\pi^2\,r^4};$$

$$k = \sqrt{\frac{R^2 + \omega^2\,L^2}{R^2}} = \sqrt{1 + \frac{\omega^2\,L^2}{R^2}};$$

which gives

$$k = \sqrt{1 + \pi^2\,r^4 \cdot \frac{\omega^2}{\rho^2}\left(2\,\log_e \frac{d}{r} + \frac{1}{2}\right)^2} \quad . \quad . \quad (3)$$

The calculation of the factor of impedance from this formula is troublesome. Mr. Kennelly has prepared tables giving k for wires from 1mm. to 10mm. diameter for distances varying from 0m. and 10m., and for frequencies of 40, 60, 80, 100, 120, and 140 periods per second values for all the frequencies obtaining in practice. Kennelly's 1893 table for frequency of 100 periods per second is here reproduced for use in calculating other frequencies and other resistances.

FACTORS OF IMPEDANCE FOR TWO PARALLEL COPPER WIRES AT 15° C.

$\frac{\omega}{2\,\pi} = \frac{1}{T} = 100$ periods per seconds. $\rho = 1688{\cdot}6$ C.G.S. units.

Distance between wires, in centimetres.	Diameter of wire ($2r$) in millimetres.					
	1	2	4	5	8	10
1	—	1·0018	1·015	1·028	1·092	1·142
2	—	1·0027	1·028	1·056	1·218	1·384
4	—	1·004	1·045	1 093	1·383	1·689
5	—	1·005	1·051	1·107	1·432	1·796
10	—	1·007	1·073	1·154	1·638	2·145
20	1·0007	1·009	1·098	1·207	1·844	2·510
50	1·0009	1·011	1·136	1·287	2·208	3·009
100	1·0011	1·014	1·169	1·353	2·373	3·394
200	1·0013	1·017	1·204	1·423	2·617	3·783
500	1·0015	1·021	1·252	1·521	2·929	4·302
1,000	1·0018	1·023	1·293	1·599	3·170	4·698
2,000	—	1·028	1·337	1·670	3·428	5·093
5,000	—	—	—	1·789	3·755	5·635

It will be seen, for instance, from (3), all other things being equal, we pass from frequency 100 to another frequency by the following process:

1. Square k.
2. Deduct 1.
3. Multiply the remainder by the square of the new frequency.
4. Divide by 10,000.
5. Add 1.
6. Extract the root, and the result gives the new factor of impedance.

Numerical Example.—Consider a double line of copper wires, 1m. apart and 1cm. diameter, traversed by an alternating current with a frequency of 120 periods per second. We find from Mr. Kennelly's table that the factor of impedance is 3·394 for a frequency of 100 periods per second. This impedance will be between three or four times that of the resistance found by means of a Wheatstone bridge.

For a frequency of 120 periods per second we shall get

1. $(3{\cdot}39)^2 = 11{\cdot}49.$
2. $11{\cdot}49 - 1 = 10{\cdot}49.$
3. $10{\cdot}49 \times 120^2 = 151{,}056.$
4. $\frac{151{,}056}{10{,}000} = 15{\cdot}1.$
5. $15{\cdot}1 + 1 = 16{\cdot}1.$
6. $\sqrt{16{\cdot}1} = 4{\cdot}01.$

Thus in passing from a frequency of 100 to one of 120, the factor of impedance is increased from 3·39 to 4·01.

If, for example, it is required to convey 10 km. ($2\,l = 20$ km.) a current of 20 amperes, the resistance of the line will be 4 ohms, and the impedance will be 16 ohms; so that in order to obtain 2,000 effective volts pressure, it is necessary to produce 2,320 at the outgoing terminals instead of 2,080, which would suffice if the line had no self-induction. It is hardly necessary to point out that the loss of energy upon the line does not correspond with the product $C^2\,R$—current squared into effective resistance; it is in this particular case $4 \times 20^2 = 1{,}600$ watts, and not the product of current squared × by impedance, which represents a quadruple loss, or 6,400 watts.

Referring to M. Hospitalier's table published in our issue of December 29, it will there be seen that the effective resistance of the conductor does not sensibly differ from the electric resistance, the self-induction being inappreciable for wires of 1cm. diameter and ordinary frequencies, but the impedance, on the contrary, is increased.

These calculations assume electrostatic capacity negligible. If capacity has to be considered, as in the case of concentric cables, or cables in juxtaposition, the formulæ are more complex, and not yet authoritatively agreed.

ELECTRICITY IN THE PANTOMIMES.

The earliest, best, and most consistent users of electrical energy for lighting purposes have been theatrical managers. Gradually, too, there is an increasing use of this illuminant for scenic purposes, and its portable form especially lends itself to artistic effect which can be obtained in no other way. Many thousands of young and old people have visited Drury Lane and the Lyceum during the present pantomime season, and have seen the use made of electricity on the stage.

A much freer use of the illuminant is made by Mr. Oscar Barrett at the Lyceum for his beautiful pantomime, "Cinderella," than is made by Sir Augustus Harris at Drury Lane. Our artist, Mr. W. M. Bowles, has visited both theatres, and in the accompanying sketches on pp. 77, 80, and 81, has attempted to delineate the uses made of the electric light. At the Lyceum the light appears in various scenes; thus in Scene 1, the "Factories of Fairyland," two fairy glass slippers on cushions appear, each being supplied with two 2½-c.p. lamps.

The fire in Scene 4, the "Kitchen at the Baron's," is produced by a cluster of ruby-coloured lamps. The vision in the overmantel is illuminated by means of a 100-c.p. lamp, with a resistance in circuit. The resistance is used to gradually bring the lamp from a state of non-luminosity to its full incandescence and then back again.

In Scene 5, the "Fairy Boudoir," the fairy slippers, electrically lighted, are again introduced, and are supposed to be placed on Cinderella's feet. Immediately lights on Cinderella's feet spring up, giving her the appearance of wearing the glass slippers. The two huge candles in this scene are each supplied with a fully-run 100-c.p. lamp, contact with the lamps being made by floor plugs. Perhaps one of the most beautiful properties in this scene is the scent-bottle. Concealed within this are 11 25-c.p. lamps so coloured as to produce prismatic tints on the glass.

The carriage in which Cinderella goes to the ball is lighted by 52 2½-c.p. lamps, all energised by a small 30 ampere-hour lithanode battery. The current used is about 65 amperes. Between each spoke of the four wheels a lamp is placed, and all the lamps are run in parallel. Although the wheels revolve, yet the current through the lamps is never interrupted, and constant luminosity is obtained. Each wheel is protected by a cut-out, and the current is under the control of one switch.

The palace entrance and terrace in Scene 7, the "Grounds of the Palace," is decorated with a large number of electrically-lighted floral sprays, each spray representing flowers in different stages of bloom. There are 26 sprays. The largest contains 10 lamps and the smallest five lamps. In each of these electrical fittings three kinds of lamps are used. The smallest lamps are arranged at the top of the sprays, and represent the flower buds. Lower down a larger-sized lamp is used, and these give the appearance of a flower just opening. Then lower down the flowers appear to be in fuller bloom, and at the base of the spray the lamps represent the full-blown flower. All the lamps are covered with a wire frame, on which is placed silk to give the desired natural colour of the flower.

Each floral fitting is mounted in a conical metal shoe which fits a metal socket which is firmly secured to the scenery. The electricity is led into the sprays by flexible wires and suitable wall plugs. All the floral fittings are detachable, and they have to be fixed and removed each time the scene is set. This is sharp work, as only 10 minutes is allowed for setting up the scene and about seven minutes for removing it.

The base of the structure forming the "palace" is divided into nine sections, and each of these has been connected up electrically by means of flexible wires and stout wall plugs. The current from the supply company's mains is carried up on to the stage, and is controlled by a switch and fuse on each lead. The wires leaving the switches are carried under the stage and terminate in a fireproof junction-box, which opens up on to the stage floor. Cables capable of carrying 100 amperes from the stage box and a junction-box are fixed on the back of the main part of the scenery. About 200 lamps are used, each taking about 0·3 ampere and 100 volts to fully incandesce them. The total current used is about 65 amperes, and the duration of light is about 15 minutes.

At the termination of this scene the lights are turned off and the electrically-illuminated slipper is discovered on the stage. The slipper used here is fitted with three 2½-c.p. lamps.

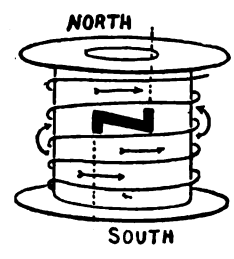
The whole of the electrical properties used on the stage in this pantomime were designed and made by the Lithanode Company and were installed by them, and are being electrically worked and maintained for Mr. Oscar Barrett by the company.

Turning from the Lyceum to Drury Lane, the recognised centre of English pantomime—where for many years Sir Augustus Harris has provided entertainments unsurpassed for spectacular effect, and where this year he has not fallen short of anything that has ever gone before—we find a mass of glitter and colour which has artistic beauties appealing to all playgoers. Sir Augustus Harris, however, has not largely employed electricity, but where he has done so it heightens the brilliancy of the scene. Perhaps one of the prettiest effects is obtained in the fish ballet, wherein troupe after troupe of imitation fish pass before the sightseers. In those members of the *corps de ballet* representing mackerel small four-volt lamps are used in the head-dress, as shown in the picture. These lamps are actuated by portable lithanode batteries, and thus a very brilliant effect is obtained. The portable batteries are two-cell batteries to give an ampere-hour. At the commencement of what we may term the pantomime proper, Mr. Harry Payne and his colleagues are introduced by Miss Kingston as "the Spirit of the Pantomime," and this spirit has the star upon her forehead, or rather upon her head-dress, in the shape of an incandescent lamp. Considerable use also is made of electricity in the transformation scene.

But perhaps the great attraction in this year's pantomime at Drury Lane is in the "English History Procession," which concludes with one of the most brilliant scenes that have ever appeared in the theatre. This procession, too, has a great educational value, for youngsters will undoubtedly recollect the variations in dress that occur in the various periods of our history far better than they will by any amount of reading, plain or illustrated.

POLARITY OF ELECTROMAGNETS.

Mr. Lopez, in the columns of our American contemporary the *Electrical Review*, gives yet another rule for finding the north or south poles of an electromagnet. He uses the letter Z as an indicator, and says: "Imagine the line which connects the parallel lines of a letter Z to be a little more



perpendicular than is usually written. Apply this letter to the electromagnet so that the connecting line of the Z shall lie in the same direction as the coil is wound, looking in the direction in which the current is flowing. The upper portion will point to the north pole and the lower to the south pole." The accompanying sketch shows the principle of the rule.

TO CORRESPONDENTS.

All Rights Reserved. *Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.*

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XI. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

A NEW DANGER.

The daily papers have lately given prominence to letters commenting on this new danger, which is nothing more nor less than the blowing up of manhole covers in electrical distributing systems. We have referred to the topic before, but the companies do not seem to adopt the obvious means of remedying the trouble. It is of the first importance to recognise that there are three factors contributing to each explosion: first, we have gas leakage; secondly, a collecting chamber for an explosive mixture; and thirdly, a spark to cause the explosion of the mixture. As regards the first, we know pretty well that the soil around all gas mains and pipes is saturated with leakage gas, and we know also that if the gas is able to collect in cavities and mix with air an explosive mixture is formed. Further, we know that the electric light cable connections are made in the manholes, and that unless we can get absolute contact at the connection there may—nay, there must be sparking. No matter how carefully connections are made, there will now and again be arcing, and the spark from the arcing will explode the gaseous mixture. The obvious remedies are, in the first place, to design the subways and manholes so as to have no collection of gas. That means ventilation, for unless the manhole is airtight the lighter gas, instead of collecting, will dissipate harmlessly in the air. We venture to affirm that many manholes are airtight, and with the slightest leakage of gas into them the moment comes when the mixture is explosive. If, however, the joints and connections are perfect, the mixture is harmless; but joints and connections are not always perfect. Thus an imperfect contact in the manhole is one of the causes of the trouble. Electrical engineers know that this gas leakage will prove troublesome, and as the gas companies will certainly not amend the ways that have been tolerated for years, it behoves the electric supply companies to adapt their designs so that the dissipation of the gas is assured. It is perfectly evidently to all who study town life that the possible uprising of a manhole cover at any moment cannot be permitted, and as the remedy is so simple the danger will not be tolerated. In some cases, the spark which causes the explosion is in no way connected with the supply mains; but it must be regretfully admitted that in certain cases it must have arisen in the manner we have indicated. If it were possible in every case to ensure perfect connections, that would be an effective remedy; but in the present state of practice it would be dangerous to recommend it in preference to ventilation. The latter would not only be equally effective, but would also have the merit of greater simplicity. There are many causes which contribute to the giving way of a joint or, at least, which render its insulation imperfect, but it is difficult to see how any properly designed system of ventilation could be so seriously interfered with as to permit of the collection of gas and air under pressure. It will be seen that we do not contemplate sparking through any other cause than bad connections; but there are other causes, which, however, mostly occur through carelessness or

laziness of workmen. Loose metallic contacts do not place themselves of their own accord in manholes or across cables, and in such cases no amount of care will guard against wilful attempts at damage. Strict supervision may partially prevent these contacts, but it is possible that the cure will be through the criminal law rather than from any other source.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

SHUNTS.

SIR,—I had written a somewhat long letter on this subject, but forbear to send it; but a few words are necessary to bring this discussion to a conclusion. So far my contention is allowed—viz., that the text-books do not explain the phenomena of shunts. Each correspondent agrees in that, though they may not agree together—and no text-book authority has been bold enough to defend his book. That is all right; perhaps in future editions authors will pay a little attention to the matter, and not waste our time, money, and temper in a vain endeavour to believe what is not correct. I thank, heartily thank Mr. Sinnott for his letter, which confirms my suspicion as to the text-books. Now a word to Mr. Yellowplush. He attempts to flatter me by placing me on a pedestal upon which he looks and runs away. According to my lights (electric), you, Sir, have merely stated that, with pressure constant, branch circuits or shunts do not interfere with each other, and thus there is no division of the original current. Mr. Yellowplush is so evidently ignorant of the whole subject that he has not yet attempted to justify his remarks, but prefers to suggest that you and I are one, and gives this, I presume, as an excuse for not explaining what the real effect of a shunt is. I have asked for a text-book which really explains, but Mr. Yellowplush has not favoured me with its title yet. I asked, does a shunt divert; and if so, what? Mr. Y. is silent on the subject. He is, however, turning out to be real nice in giving me a high position in journalism, but having ere now been identified as "G. A. S.," I am not so proud of the position he affects to suggest I fill as I might otherwise be. An artist of my acquaintance hinted that a mixture with sky-blue might better show his real colour, but my education is defective in colour-mixture. So I must leave some more learned brother to say what the result would be.—Yours, etc.,

H. L.

HIGH-SPEED ELECTRIC RAILWAYS.

SIR,—With reference to Mr. Wolff's letter in your last issue under the above title, I hasten to thank him for his endeavour to explain the disparity between the air resistance values mentioned in my article, and at the same time to express my fear that his explanation does not quite "fill the bill." When writing, I purposely made the statement conditional, "If this—*i.e.*, the air resistance—be considered to act wholly in a direction parallel to the line of travel, with close-coupled cars," etc.

I would not like to affirm absolutely that only the head resistance need be taken into account, even when the train has specially-shaped ends, is built without projections, and is coupled up so closely as to offer a continuous surface on the sides and intermediate ends; but I certainly think Mr. Wolff assumes too much when he says he "*knows* that skin friction forms a large part of the resistance, and *varies with the square of the velocity*."

So far the latest experiments tend to show that even the head resistance varies with the first and not the second power of the velocity, and I do not think the skin friction would follow any different law. Then the amount of skin friction in the case discussed is extremely small—so small as to create a disparity in the other direction.

If the air resistance is assumed to act equally over the whole area of train—say 8,000 square feet—then its value hardly exceeds $\frac{3}{8}$lb. per square foot; whilst if we take 15lb. per square foot for the head resistance, then the side resistance representing the skin friction is only $\frac{1}{5}$lb. per square foot.

This may be a fair average value, but I very much doubt whether the effect of this side resistance is at all as great as Mr. Wolff supposes. It may in some cases be to no small extent balanced by the air eddies at the end of the train.

Of course, on ordinary steam railroads at usual speeds, side winds cause a much greater demand on the coal-pile than those dead ahead; but this is not by any means solely because of the extra air resistance. The tilting over of a train by wind pressure throws more weight upon one side, and increases the track resistance enormously, with a corresponding call for more energy from the locomotive.

With a train properly designed and constructed I doubt very much whether the skin friction, *per se* (especially at high speeds), requires the expenditure of any serious amount of energy; certainly not to the same extent as the head resistance. As I stated, however, in my article, the absolute lack of reliable data upon this and kindred points, makes it impossible to dogmatise in any way. One can only assume—perhaps incorrectly.—Yours, etc.,

FRANK B. LEA.

THE TENDENCY OF BUSINESS.

SIR,—It appears from your leader of last week that you regard my remarks with reference to sub-companies as reprehending to some extent the character of the business done in the past in supply-station work. My remarks should not have conveyed this meaning, as I merely called attention to the fact that the larger manufacturing concerns had a considerable holding in sub-companies, and that the taking of shares for work done had greatly quickened the development of the electrical industry towards its final stage of evolution. The result is that the firms which assisted in the promotion of companies in the early stages now get the bulk of supply work, while those which could not command capital have gradually settled down to work in other branches. That progress would have been greatly delayed if business had not been thus *made*, is precisely what by inference I pointed out; and it by no means follows that I regard sub-companies as an evil, or that I regret the circumstance that the shareholders in electric manufacturing enterprises become incidentally shareholders in supply companies. This factor has had a great directional influence on the industry, and that is all I wished to point out.—Yours, etc.,

W. B. ESSON.

THE EARL'S COURT EXHIBITION.

SIR,—We observe in your business notices for 1893 you state that the Brush Company supplied the whole of the electrical plant at the Earl's Court Exhibition. As this statement would lead your readers to suppose that the arc lamps were included in the plant, we beg to say that both inside the building and in the gardens the standard "Brockie-Pell" arc lamp was used throughout.—Yours, etc.,

JOHNSON AND PHILLIPS.

14, Union-court, Old Broad-street, E.C., Jan. 15, 1894.

THE TESLA ELECTRICAL OSCILLATOR.*

In the lecture delivered before the Chicago Electrical Congress, Mr. Nikola Tesla first drew attention to the method and means which he had devised for the continuous production of alternating currents of constant period, and in which all rotating parts are avoided by the employment of his oscillating engine directly to the movement of the generating coil in the magnetic field.

The main reason why no engine heretofore has been capable of producing results of this nature is that it has been customary to connect with the reciprocating parts a heavy flywheel, or some equivalent rotary system of relatively very great inertia, or in other cases where no rotary

* From an advance proof of the *Electrical Engineer* (New York).

Digitized by Google

system was employed, as in certain reciprocating engines or tools, no regard has been paid to the obtainment of the conditions essential to the end which Mr. Tesla had in view.

In applying the Tesla oscillator for the generation of currents of constant period, certain conditions are encountered which must be taken into consideration in order to satisfactorily secure the desired result. When a conductor is moved in a magnetic field and a current caused to circulate therein, the electromagnetic reaction between it and the field might disturb the mechanical oscillation to such an extent as to throw it out of isochronism. This, for instance, might occur when the electromagnetic reaction is very great in comparison to the power of the engine, and there is a retardation of the current, so that the electromagnetic reaction might have an effect similar to that which would result from a variation of the tension of the spring; but if the circuit of the generator be adjusted so that the phases of the E.M.F. and current coincide in time—that is to say, when the current is not retarded—then the generator driven by the engine acts merely as a fractional resistance, and will not, as a rule, alter the period of the mechanical vibration, although it may its amplitude. This condition may be readily secured by properly proportioning the self-induction and capacity of the circuit, including the generator.

Mr. Tesla has, however, observed the further fact in connection with the use of such engines as a means for running a generator, that it is advantageous that the period of the engine and the natural period of electrical vibration of the generator should be the same, as in such case the best conditions for electrical resonance are established, and the possibility of disturbing the period of mechanical vibrations is reduced to a minimum. Mr. Tesla has found that even if the theoretical conditions necessary for maintaining a constant period in the engine itself are not exactly maintained, still the engine and generator combined will vibrate at a constant period. For example, if instead of using in the engine an independent cylinder and plunger, as an air spring of practically constant rigidity, the piston may impinge upon air cushions at the ends of its own cylinder. Although the rigidity of such cushions or springs might be considerably affected and varied by the variations of pressure within the cylinder, still by combining with such an engine a generator which has a period of its own, approximately that of the engine, constant vibration may be maintained even through a considerable range of varying pressure, owing to the controlling action of the electromagnetic system.

Indeed, Mr. Tesla has even found that under certain conditions the influence of the electromagnetic system may be made so great as to entirely control the period of the mechanical vibration within wide limits of varying pressure. This is likely to occur in those instances where the power of the engine, while fully capable of maintaining a vibration once started, is not sufficient to change its rate.

In our issue of November 8, 1893, we gave the details of construction of the Tesla oscillator, and a patent just issued to Mr. Tesla now enables us to supplement our previous descriptions with those of other types employed by him in this work. The accompanying engraving, Fig. 1, is a sectional view of an oscillator fulfilling the conditions laid down above.

Referring to Fig. 1, A is the main cylinder in which works a piston, B. Inlet ports, C C, pass through the sides of the cylinder opening at the middle and on opposite sides. Exhaust ports, D D, extend through the walls of the cylinder, and are formed with branches that open into the interior of the cylinder on each side of the inlet ports and on opposite sides of the cylinder. The piston, B, has two circumferential grooves, E F, which communicate through openings, G, in the piston with the cylinder on opposite sides of the piston respectively. The particular construction of the cylinder, the piston, and the ports controlling it may be very much varied, and is not in itself material, except that in the special case under consideration it is desirable that all the ports, and more especially the exhaust ports, should be made very much larger than is usually the case, so that no force due to the action of the steam or compressed air will tend to retard or affect the return of the piston in either direction. The piston, B, is secured to a piston-rod, H, which works in suitable stuffing-boxes in the heads of the cylinder A. This rod is prolonged on one side and extends through bearings, V, in a cylinder, I, mounted in line with the first, and within which is a disc or plunger, J, carried by the rod, H. The cylinder, I, is without parts of any kind, and is airtight except as a small leakage may occur through the bearings, V, which experience has shown need not be fitted with any very considerable accuracy. The cylinder I is surrounded by a jacket, K, which leaves an open space or chamber around it. The bearings, V, in the cylinder, extend through the jacket to the outside air, and the chamber between the cylinder and jacket is made steam or air tight by a suitable packing. The main supply pipe, L, for steam or compressed air leads into this chamber, and the two pipes that lead to cylinder A run from this chamber, oil-cups, M, being conveniently arranged to deliver oil into the pipes for lubricating the piston.

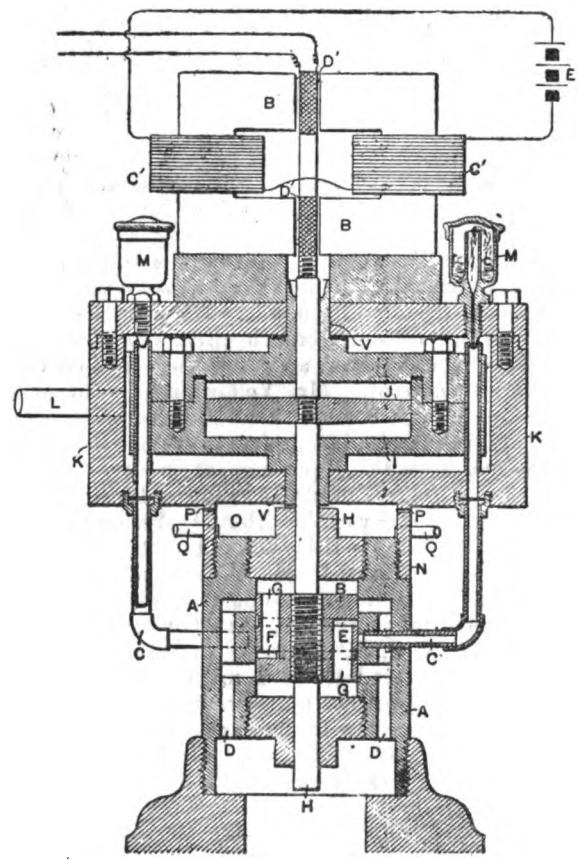

FIG. 1.

In the particular form of engine shown, the jacket, K, which contains the cylinder I is provided with a flange, N, by which it is screwed to the end of the cylinder A. A small chamber, O, is thus formed which has air-vents, P, in its sides, and drip pipes, Q, leading out from it through which the oil which collects in it is carried off. In the position of the parts shown, or when the piston is at the middle point of its stroke, the plunger, J, is at the centre of the cylinder I, and the air on both sides of the same is at the normal pressure of the outside atmosphere. If a source of steam or compressed air be then connected to the inlet ports, C C, of the cylinder A, and a movement be imparted to the piston as by a sudden blow, the latter begins to reciprocate in the well-known way. The movements of the piston compress and rarefy the air in the cylinder I at opposite ends, alternately. A forward stroke compresses the air ahead of the plunger, J, which acts as a spring to return it; similarly, on the back stroke the air is compressed on the opposite side of the plunger, J, and tends to drive it forward. The compressions of the air in the cylinder, I, and the consequent loss of energy due mainly to the imperfect elasticity of the air, gave rise to a very considerable amount of heat. This heat is utilised by conducting the steam or com-

Digitized by Google

pressed air to the engine cylinder through the chamber formed by the jacket surrounding the air-spring cylinder, the heat thus taken up and used to raise the temperature of the steam or air acting upon the piston is availed of to increase the efficiency of the engine.

In any given engine of this kind the normal pressure will produce a stroke of determined length, and this will be increased or diminished according to the increase of pressure above, or the reduction of pressure below, the normal. In constructing the apparatus proper allowance is made for a variation in the length of stroke by giving to the confining cylinder, I, of the air spring properly determined dimensions. The greater the pressure upon the piston, the higher will be the degree of compression of the air spring, and the consequent counteracting force upon the plunger. The rate or period of reciprocation of the piston, however, is mainly determined by the rigidity of the air spring and the inertia of the moving system, and any period of oscillation within very wide limits may be secured by properly portioning these factors, as by varying

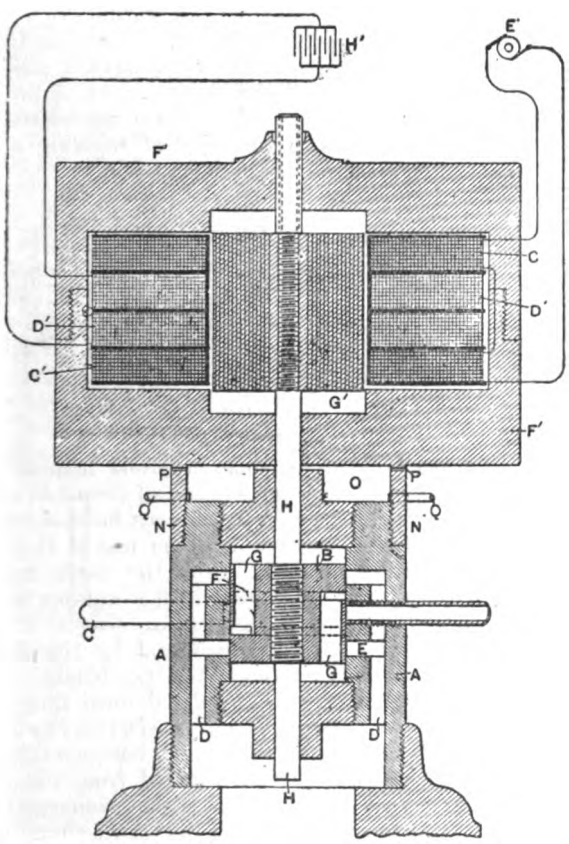

FIG. 2.

the dimensions of the air-chamber, which is equivalent to varying the rigidity of the spring, or by adjusting the weight of the moving parts. These conditions are all readily determinable, and an engine constructed as above described maintains a perfectly uniform period through very wide limits of pressure. The pressure of the air confined in the cylinder when the plunger, I, is in its central position will always be practically that of the surrounding atmosphere, for while the cylinder is so constructed as not to permit such sudden escape of air as to sensibly impair or modify the action of the air spring there will still be a slow leakage of air into or out of it around the piston-rod according to the pressure therein, so that the pressure of air on opposite sides of the plunger will always tend to remain at that of the outside atmosphere. To the piston-rod, H, is secured a coil, D', which, by the movements of the piston, is oscillated in the magnetic field produced by two magnets, B' B', which may be permanent magnets or energised by coils, C' C', connected with a source of continuous current, E'. The movement of the coil D' across the lines of force established by the magnets gives rise to alternating currents in the coil. These currents, if the period of mechanical oscillation be constant, will be of constant period. In the case under consideration it is assumed as a necessary condition that the inertia of the movable element of the generator and the electro magnetic reaction which it exerts will not be of such a character as to materially disturb the action of the engine.

Fig. 2 is an example of a combination in which the engine is not of itself capable of determining entirely the period of oscillation, but in which the generator contributes to this end. In this figure the engine is the same as that shown in Fig. 1. The exterior air spring is, however, omitted, and the air-spaces at the ends of the cylinder, A, relied on for accomplishing the same purpose. As the pressure in these spaces is liable to variations from variations in the steam or gas used in impelling the piston they might affect the period of oscillations, and the conditions are not as stable and certain as in the case of an engine constructed as in Fig. 1. But if the natural period of vibration of the elastic system be made to approximately accord with the average period of the engine, such tendencies to variation are very largely overcome, and the engine will preserve its period even through a considerable range of variation of pressure. The generator in this case is composed of a magnetic casing, F', in which a laminated core, G', secured to the piston-rod, H, is caused to vibrate. Surrounding the plunger are two exciting coils, C' C', and one or more induced coils, D' D'. The coils C' C' are connected with a generator of continuous currents, E', and are wound to produce consequent poles in the core, G'. Any movement of the latter will therefore shift the lines of force through coils D' D', and produce currents therein. In the circuit of coils D' is shown a condenser, H'. By the use of a proper condenser the self-induction of this circuit may be neutralised. Such a circuit will have a certain natural period of vibration, and, as this depends upon the capacity and self-induction, the period may be varied to approximately accord with the period of the engine.

In case the power of the engine be comparatively small, as when the pressure is applied through a very small fraction of the total stroke, the electrical vibration will tend to control the period, and it is clear that if the character of such vibration be not very widely different from the average period of vibration of the engine under ordinary working conditions, that such control may be entirely adequate to produce the desired results.

ELECTRIC RAILWAY MOTORS: THEIR CONSTRUCTION AND OPERATION.*

BY NELSON W. PERRY.

Some years ago I became acquainted, as a boarder, with a bright young man who introduced himself to me as an electrician. It happened we were placed at the same table, and as he was of an affable disposition we soon became very well acquainted. Whenever the subject of electricity came up, he was accustomed to speak in such a way as to impress all his hearers with the idea that he was an authority on all such subjects whose opinions were not to be questioned, and as he was generally correct in his statements, I also became somewhat impressed with his knowledge, and would often ask questions—sometimes for information and sometimes to see how nearly his opinions coincided with my own.

I found that he had been sent out by the then leading company engaged in electrical railway construction, and his business in that city (a Western one) was the construction of its first electric railway. We soon became quite good friends, and when the power-house was nearing completion I was a privileged character within its walls, for visitors were rigidly excluded as a rule; and, later, when the first tests of the operation of the road were made, I was one of the fortunate few invited guests.

The first car over the line started out from the barns at 10 o'clock at night, and carried as passengers, besides myself and the gentleman referred to, but three others—all officials of the road. Everything went smoothly until the further terminus—about three miles distant—was reached, when something gave way and we were stalled.

* From the *Street Railway Gazette*.

Digitized by Google

I must add here that my friend had not yet discovered that I was myself an electrician. I had had no other object in concealing the fact than that as I had not been asked my business, it had never been necessary for me to declare it, and I felt that he would talk with me more freely if he did not know it. He knew that I was an engineer, however, and he attributed my ability to solve certain questions which arose to that fact—to that combined with what he took to be a smattering of electricity which he supposed I had acquired in some way or other.

As a matter of fact, however, I considered myself a full-fledged electrical engineer, and was as electrical engineers went in those days, for besides having had a pretty thorough training on the purely theoretical side of electricity, I had worked in two of the largest shops in the country in all the departments of electrical manufacture. I had wound armatures and fields, and assisted in making and dressing down all the other parts of machines, both large and small, had assembled these various parts, connected them up, soldered the connections, and finally tested the completed machines. I had also assisted in installing one road myself, and had inspected every road but one that was at that time in operation in the country, so that I was pretty familiar with electric railway construction as then developed. I knew that my friend's experience had not been nearly as wide as my own, and I was glad to be with him on the occasion of the opening test of this, which I suspected was the first road over whose construction he had been completely in charge.

Well, as I say, something had happened, which was only really discovered when the attempt was made to run the car back. There was a considerable grade at starting, and this the car failed to ascend. We backed down to the level and tried it again. The car worked all right until the grade was reached, when she stopped again. This was repeated a number of times, and always with the same result. My own experience made me suspect at once the true trouble, but it would not do for me to suggest. My friend had been playing the *rôle* of a great authority on electric railroad matters for the special benefit of his invited guests on the car. He was in very high feather, and not without reason, that night, because the work of his hands was finished, and now he was showing his admiring guests how immeasurably better it worked than even his own anticipations had led him to hope.

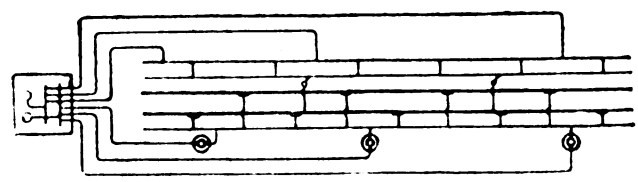
For me to have suggested the cause would been considered a piece of impertinence of the highest order, not only by him, but by the other guests, who looked upon my friend as a wonderful man; so I kept quiet.

My friend was a man of great self-confidence and equal to the emergency. In reply to enquiring glances, he said it was due to "something or other"—using a term not down either in Webster's or Houston's dictionaries—that it was a very trivial matter and could easily be fixed; he would back down to the level again and fix it. He did so—that is, he backed down—and, after making an examination, said: "Yes, that's it, just as I thought; the 'something or other' was just what caused the trouble," and he straightway proceeded to correct the thing. In the meantime I had had an opportunity of verifying my suspicions, but, of course, kept my counsel. When all was declared ready we entered the car again, and my friend, who really had done nothing, as far as I had been able to see—he certainly hadn't touched the root of the trouble—turning on the current to the last notch, said, "Now we go," and we did, until we had gotten even a little way beyond the point on the grade where we had always stalled before, and then we stalled again. We had gained a few feet over previous attempts simply because we had gained a little more momentum on the level. I think my friend understood this as well as I, but he pointed to the small gain with apparent pride, and with unblushing assurance stated that that proved that he knew he was right in locating the trouble, and that now he would run back and fix the thing for good. We went back, and he got under the car again. I watched him closely this time, and, after doing absolutely nothing more than fumble around a little, he came out and announced that "Now I've fixed her for good, and I'll show you how we can mount that grade."

(To be continued.)

VAIL'S SYSTEM OF DISTRIBUTION FOR ELECTRIC RAILWAYS.

Many efforts have been made to increase the efficiency of a system of distribution in which the rails form part or all of the return circuit. The principal defects of such systems are its interference with grounded telephone circuits, its damaging effects on gas and water pipes, and often its high resistance, which may cause serious and undesirable fall of potential on parts of the line removed from the source of supply. To avoid the difficulties, Mr. J. H. Vail has devised the arrangement of circuits shown in the accompanying illustration. The positive and negative terminals of the generating plant are connected in the usual manner to the 'bus bars at the station. A continuous main conductor extends along the line, either carried upon poles or placed underground, and this is connected at intervals by branch conductors with the trolley line. Extending from the positive 'bus bar in the central station a suitable number of conductors are carried to different distances from the station where they are connected to the main conductor. These conductors are each of such size and capacity as to have a predetermined drop in potential, and the points at which they are connected with the main conductor are mathematically determined in advance with the object of securing a constant potential on all parts of the main conductor.



Vail's System of Distribution.

The rails are bonded in some suitable manner with metallic connections so as to make the rail circuit as nearly complete as possible. Another continuous main conductor for the return circuit is carried along the line of the road, and this is carefully insulated from the earth by supporting it upon poles or by placing it in a suitable insulating underground conduit. This return circuit main is connected at intervals with the rails, and for the sake of convenience this is made through the rail bonds. These branch connecting lines are also insulated until they reach their connections with the rails. If preferred, the return circuit main may be placed underground between the rails, but in this case, as before, it is insulated from the earth. The negative 'bus bar at the station is then connected by a suitable number of conductors with the return circuit main, these extending to different distances from the station, and the points of contact being so calculated in advance that each will have the same potential. By this means the difference of potential between the terminal of any car motor remains practically constant, as it travels along the line and its distances from the source of power varies.

Instead of connecting a feeder to the main line conductor at a single point, a number of connections by different wires are made within, say, the space of 100ft., so that while, electrically considered, the connections are all at a single point, there are a number of independent connections, the breaking of any one or more of which will not interrupt the circuit.—*Street Railway Gazette.*

Magnetised Side-Arms.—It is reported that bayonets belonging to marines on board her Majesty's ships have in certain cases become highly magnetised through contact with, or close proximity to, dynamos, or from other causes, the result being that compasses have become affected by sentries passing near them when wearing these side-arms. In future sentries are not to wear side-arms when on duty in the dynamo flats, and this is expected to overcome the difficulty.

THEORY OF HYSTERESIS.

BY CHAS. A. PERKINS.

The energy absorbed by a cubic centimetre of iron when its magnetism is reversed is equal to the area of a curve whose co-ordinates are H and I. No doubt many persons are constantly making use of this fact without understanding why it is true. Even in Fleming's work on the "Alternate-Current Transformer" (vol. i., p. 65) the reader is referred to a somewhat abstruse paragraph in Maxwell's treatise for the proof.

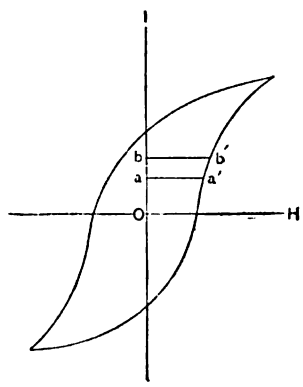
The following explanation will, however, serve to make the matter plain to anyone who understands the definitions of magnetic quantities and the principles of work and energy.

A magnetic pole of strength m when in a field of strength H is acted upon by a force m H. If it is moved a distance l in the direction of the magnetic force, the work done is $m\,l$ H. (This is the work done by the pole; but we shall pay no attention to the sign to be attached, as we are calculating only the amount of the work.)

Now let us conceive of a magnet whose length can be changed (as if it were made of indiarubber).

Let one pole stand still and the other be moved by stretching the magnet from a length l_1 to a length l_2. The work done by the magnetic force will be H m $(l_2 - l_1)$ or H $(m\,l_2 - m\,l_1)$. Now $m\,l$ is the magnetic moment of the magnet, and the intensity of magnetisation, I, is $\frac{m\,l}{\text{volume}}$.

If for convenience we take a unit volume (one cubic centimetre), then we may write $I_1 = m\,l_1$ and $I_2 = m\,l_2$ and H $(I_2 - I_1)$ is the work required to change the intensity of magnetisation from I_1 to I_2. Although we supposed this change to be made by stretching the magnet, it makes no difference how it is done if the final result is the same, and H $(I_2 - I_1)$ still represents the work required, whatever be the process of changing the value of I.



Now, in the diagram let O a represent I_1 and O b_1 I_2, then the area $a\,b\,b'\,a'$ is the value of H $(I_2 - I_1)$, and therefore represents the work required to change the magnetisation from I_1 to I_2. The whole area of the curve is made up of such areas, and therefore represents the energy necessary to perform the process indicated by the curve—viz., to magnetise the iron, demagnetise it, reverse its magnetism and again bring it back to the original condition.

The process of building up such a curve from small slices is familiar to all those who understand the principle of the indicator diagram.—*Electrical World.*

ELECTRICITY IN 1876 AND IN 1893.

BY ELIHU THOMSON.

Over a hundred years ago Tiberius Cavallo wrote in his introduction to "A Complete Treatise on Electricity" as follows: "Discoveries crowded upon discoveries, improvements upon improvements, and the science ever since that time went on with so rapid a course and is now spreading so amazingly fast, that it seems as if the subject would be soon exhausted, and electricians arrive at an end of their researches; but, however, the *ne plus ultra* is, in all probability, as yet at a great distance, and the young electrician has a vast field before him highly deserving his attention, and promising further discoveries perhaps equally or more important than those already made."

This was before the voltaic battery became known, before Davy experimented with it and produced the electric arc between carbon points, before metals were deposited in electrolysis, before the effects of electric currents on magnetism was discovered, before anything was known of the extensive fields of electromagnetic and magneto-electric induction, before the telegraph, the telephone, the electric light, the electric motor, the electric railway, the art of electric metal-working, and indeed before everything which now marks electrical science as of such great importance in our time.

I have quoted the passage above as aptly expressing a thought which has, doubtless, in these later years arisen in many minds. It might well have been written in the present year of the World's Columbian Exposition in view of the exemplification there made of the great progress in electrical arts during the period since the Centennial, 17 years ago. No similar period in the world's history has in any art shown so rapid development, so extensive and refined scientific study and experiment, so active invention, so varied application, such care and perfection in manufacture, as has taken place in the electrical field within the period mentioned.

It can be truly said that as a department of applied science and engineering, electricity has taken an important place only within the past 10 or 12 years. I do not forget that before the Centennial we had the telegraphic engineer, with his knowledge of batteries, lines, relays, sounders, etc.—a sufficient equipment for his work which was then the most important electrical application. I do not neglect the cable engineer, with his more refined and delicate methods, due to the somewhat different conditions required to be met with in the construction and operation of submarine lines. Electro-metallurgy, including electroplating and electrotyping, had already become of great utility when the Centennial year opened. But 17 years ago there were no dynamos in regular operation for electric lighting in the country, although a few machines of the Gramme and Alliance types were used abroad. Special forms of dynamo machines had been designed for electro-metallurgy, and a number of them were in use, but installed only a short time prior to 1876. Small magneto machines had been employed for a number of years previously as substitutes for primary batteries in exploding fuses for blasting and torpedo service. Electric motors, hardly worthy of the name, were here and there operated at great cost from primary batteries, but they were of insignificant power, and resembled the old designs which figured so largely in catalogues and collections of philosophical apparatus—instructive enough in their way, but of no practical value.

What, then, was comprised in such electrical exhibits as were found at the Centennial Exhibition in Philadelphia? Living there, and working in the electrical field, I remember that I possessed a lively mental sense of the ultimate vast utility of electrical forces which caused me to employ the opportunities afforded for study of such exhibits as from a practical or scientific standpoint showed distinct advances. There were in the main building a number of such exhibits as telegraphic apparatus and systems of signalling, electric clocks, burglar-alarms, and the like. In the class of philosophical instruments were the usual electric models for educational purposes. Electric key action was found applied to organs and automatic playing of the same. In Machinery Hall were to be found a few crude electric motors run by expensive and noisome primary batteries. Such motors were of but small power, and belonged to the old types, with electromagnets and bar armatures successively attracted or repelled. The application of dynamo-electric machines to electroplating, then in itself quite a novelty, was represented by Weston machines of fair size. In these machines some of the principles of modern self-exciting dynamos were found, but the armatures were of the old-style polar pattern with a single winding terminating in the usual pair of plates called a commutator.

But we need not further concern ourselves with these exhibits. They gave but small indication of the future of electrical progress. There was nothing in them to indicate or suggest that the world was on the eve of great advances so soon to be made.

There were, however, two exhibits in Machinery Hall of great interest to electricians as showing types of electrical machinery, which in various modified forms were soon to work revolutions in lighting and transmission of power. These two exhibits were of the Gramme and Wallace machines. Neither was remarkable for the floor space covered, but notwithstanding their modest extent, and the fact that they were sandwiched in between exhibits of entirely different class and widely separated one from the other, there was that in each of them which could not fail to be of deep interest to an electrical worker. The Gramme machine itself had become known in the United States through descriptions in scientific

Digitized by Google

journals, and there had been two or three machines imported into the country. Two of these I had the opportunity of inspecting a year or two before. Another Gramme machine—built at Cornell University, if I remember rightly—was sent as an exhibit to the Centennial Exhibition. This was probably the first dynamo of the kind built in the United States.

In the Gramme space itself could be seen a small belt-driven dynamo giving current for the working of a single arc lamp in its circuit, series working being unknown at that time. In this space also there was an arrangement of circuit whereby one machine, driven by the belt as a generator, furnished current through some 20ft. or 30ft. of wire to a second similar machine, which then ran as a motor. This was, in turn, belted to a small centrifugal pump, which produced a small cataract of water. Experiments were also made from time to time in the heating and melting of wires by the current generated by the machines on exhibition. Special coarsely-wound low-potential Gramme dynamos for electroplating were among the interesting features. I remember the feeling of admiration—I might almost say exultation—with which I viewed this most unique exhibit. I also remember the enthusiasm of the attendant, whose voice held firmly to its French, and musically rolled off the catalogue of the capabilities of the Gramme machine, "la lumière électrique, la galvanoplastie, le transport de force motrice, la telegraphie," etc.

I need not remind the technical reader that the Gramme machines were the first dynamos of the true modern type constructed—the armature iron being circular in outline and preserving its relation to the magnetic field while rotating, and the winding thereon being continuous, with leads taken at intervals to a commutator of many segments. The result was a smooth unbroken current resembling that from batteries. While in these machines the core was a ring and the wire was wound over and through the same, the subsequently developed drum type differed from it only in the disposition of the closed armature winding all on the outside of the ring core instead of through its centre.

The exhibit of Mr. William Wallace was unique in showing a number of different types or forms of dynamo, while the Gramme machines were substantially alike in pattern. The Wallace machines furnished current for single arc lamps, for plating-baths, and were reversed and run as motors. This exhibit was very suggestive of types and forms which afterward came into general use, and, fortunately, the machines themselves were preserved and sent to the World's Fair in the present year—a retrospect, as it were, of the Centennial exhibit. Historically considered, such early models are now invaluable. Space does not permit any detailed reference to them. Some of them were used—as were the Gramme machines—for furnishing current to work large reflector lamps, similar to search-lights, mounted on the roof of Machinery Hall, on occasions of evening celebration, with fireworks and other displays.

The Centennial will be remembered in the history of electrical progress on account of the fact that the telephone of Alexander Graham Bell became then for the first time known as an accomplished fact. It spoke with a small voice, it is true, at the Centennial Exhibition, but the echo of that voice was heard over the civilised world. The telephone had been invented just in time to date its birth from 1876. Dr. Elisha Gray, who was close upon Bell in the invention of the telephone itself, was exhibiting his harmonic telegraph, a very ingenious multiple telegraph, but the chief interest soon centred on the instrument that could talk. With the advent of the speaking telephone there seemed to come about a general awakening to the capabilities of electricity in practical work. It prepared the public mind for the coming of new wonders. It attracted attention to other electrical enterprises, and to a large extent wiped out the factor of conservatism in relation thereto. Indeed, the telephone had scarcely begun to be used practically before the announcement of the invention of the Jablochkoff candle drew attention to the field of electric lighting, and in 1878 the Avenue and Place de l'Opera, lighted by electric candles, constituted one of the great achievements of the Paris Exposition year. The Jablochkoff candle did not, however, realise expectations; it was too costly, and soon gave place to ordinary arc lamps run in series. Much pioneer work in this field was done in this country by Mr. Charles F. Brush, of Cleveland, who in 1879 had as many as 16 arc lamps running in series from one of his well-known dynamos. A few other inventors were almost equally early in this work.

It was towards the close of 1879 that Thomas A. Edison succeeded in accomplishing the task which he had undertaken and upon which he had been at work for a year or two. This was the invention of a small electric light giving a light of about the same candle-power as a gas-jet, and capable of being run in multiple with many others, without requiring too large a current or too frequent renewals of the lamp. Such a lamp to be commercially successful needed to be of low first cost, economical of power, and easily reproduced in large numbers. No one unless he has been engaged in similar undertakings can begin to realise the amount of effort, self-sacrifice, and hard work which must have been required not only to perfect the lamp itself and the details of its manufacture, but to provide suitable generators, regulators, distributing systems, mains, safety devices, and the other things which go to make complete the electrical equipment of a lighting installation—a revolution in lighting means and methods. That Mr. Edison and his able assistants undertook and accomplished this work, the records of the numerous inventions in this field would be sufficient evidence, did we not have the fact of the actual accomplishment as a matter of engineering history.

It would be beyond the scope of the present paper to trace the history of the innumerable developments in the electrical field brought about by the effort and genius of a great army of workers, both here and abroad, between the year 1876 and the present. It must not be forgotten either that, aside from the great engineering triumphs which are from their practical benefits sufficiently prominent, electrical science, purely as a science, has expanded and progressed apace.

The advance, though a rapid one, has been sufficiently gradual to allow us to note the process as more of evolution than revolution. The great exhibitions held within the period between 1876 and 1893 have embodied more and more electrical arts and productions. Add to these the specially electrical exhibitions—as in Paris (1881), Philadelphia (1884), and Frankfort, 1891—and the growth becomes evidently a gradual unfolding. It was natural, then, not only that the World's Fair of this year should have been characterised by progress in all arts, but that it should have become more distinctively electrical than any preceding international display. It is to be doubted, however, if many were prepared to find that such dependence on the work of the electrical engineer would be shown.

Whether we regard the lighting of the vast areas and spaces in and around the great structures in Jackson Park, or the transportation by rail or water within its boundaries, or the distribution of power for various purposes, it was through the agency of electricity that these objects were attained. In fact, the great bulk of the steam power developed was to give motion to the dynamos for furnishing current for all the various uses to which in these days electricity has been applied. It is certainly no exaggeration to say that the vast amount of mechanical power developed and used at the World's Fair was mostly used for electrical purposes or transmitted electrically for its ultimate use. A vast area in the Mechanic Arts Building, covered with engines and dynamos driven thereby, directly adjoined the boiler-houses and formed for the time, as it were, the most gigantic electric station ever installed. From it was sent out current for several thousands of arc lights, for from 50,000 to 100,000 incandescent lights, for innumerable electric motors working elevators, driving machinery of all kinds, ventilating, for charging storage batteries, for electric welding, forging, heating, and other uses.

At the Centennial in 1876, no perceptible fraction of the power was electrically used. At the World's Fair it had become almost wholly electrical. The arrangement of the great Corliss engine at the Centennial was in the middle of the Machinery Building, and by a complex system of gears and belts the power was transmitted and delivered to the long lines of shafting extending each way from this central power source. This was a limitation of service arising directly out of the absence of electrical transmission. At the World's Fair, on the other hand, power could be delivered anywhere by the use of electric motors, and the moving machinery was not therefore practically restricted to a building in which a steam-engine was at hand.

In 1876 arc lights were a curiosity and but rarely seen. In 1893 their use for illumination of streets and large spaces is almost universal. Never has there been, however, any greater display of arc lighting than in the present year at the World's Fair. The whole of Jackson Park was dotted over with these miniature suns at night and the interiors lighted. Under the roof of the Manufactures and Liberal Arts Building were five large coronas comprising many arc lamps each, a unique display in itself and an economical arrangement as well. About 2,000 arc lights, if I mistake not, were employed in lighting the gigantic structure throughout. The great search-lights, with their 60in. mirrors reflecting the light from specially large arcs in their foci, were a striking feature of the illuminations, and these artificial sunbeams were of an intensity never before approached.

The whole art of lighting by electric incandescence has come into existence since 1876. Incandescent lamps can now be made of such uniformity of voltage and energy consumption as even to dispense with any need of photometric measurement, and, indeed, to require no testing or sorting after manufacture. Such lamps may consume about 3½ watts per candle and have a useful economical life of over 1,000 hours of service. An achievement like this means attention to many small details, and the doing of delicate work on a large scale. Astonishing it is to find that frequently in such work, what was formerly a delicate laboratory manipulation becomes every-day workroom practice; and here constant practice of delicate operations by even ordinary labour results finally in almost perfection.

Digitized by Google

The larger part of the incandescent lighting of the World's Fair—and the little bulbs were everywhere used and useful—was carried out on the alternating-current plan so commonly employed in cities and towns where the electric station must be at a considerable distance from the mass of consumers. Huge dynamos in the Mechanic Arts Building supplied the alternating current at high pressure in mains leading to the transformers, located in receptacles in the ground, from the secondary circuits of which the low-pressure currents were fed to the lamps connected thereto.

At the time of the Centennial, alternating currents were known, and dynamos yielding such currents were known, being among the earliest invented, but the transformer was unknown. The nearest approach to it was the induction coil for shocks or medical use and the Ruhmkorff coil. Soon after the invention of the telephone, however, the induction coil, modified and used in conjunction with carbon transmitters, enormously increased the distance over which speech could be successfully transmitted, and has led in 1893 to the regular communication by telephone over distances more than a thousand miles, while such is the delicacy and fidelity of transmission that it is not necessary to speak much above a whisper at New York or Boston to be heard in the receiver at Chicago.

The transformer, or modified induction coil, has in like manner render possible the economical transmission of electric energy to great distances, as the working of low-voltage incandescent lamps at miles of distance from the supply station. Otherwise, the line losses and excessive cost of mains would in such cases forbid the use of direct supply. The perfection to which this useful apparatus, the transformer, has been brought by careful work may be judged from the fact that it often has an efficiency between 97 and 98 per cent. at full load. It is a simple affair of copper wire and sheet iron apparently, but it has required much study and experiment to bring it to the present state of perfection. There is little or no opportunity for further advance. The very great expansion of incandescent lighting both by the direct-supply systems and transformer systems during late years is sure to continue at an increasing rate in the future until it includes a large proportion of the lighting done in cities and towns.

In 1876 the storage battery was practically unknown. A crude form devised by Planté had been experimented with for a considerable time before in the laboratory. The eminently successful use made of the electric launches on the lagoons at the World's Fair was an ample demonstration that in the past few years a new field for electrical work had been opened up. The application of the battery to boats is of course but one of the uses for the modern storage cell. Many electric stations in Europe, and a few in the United States, have within late years added an equipment of batteries to work in conjunction with their dynamos in giving out current energy when the consumption is heavy, and to absorb energy or become charged from such machines when the consumption is small. This in a large measure prevents overloading at one time, or the running of the machinery with loads too light to be economical at other times. How far experience will confirm the apparent advantage of such a plan remains to be seen.

The largest single exhibit of an electrical nature was without doubt the Intramural railway and its power-house—together a grand practical exemplification of electricity applied to traction. It was remarkable in many ways as a piece of engineering and operated with the greatest success. It emphasised the fact that the days of steam locomotives on elevated roads in cities are numbered, and that just as surely as the horse-car has given place to the trolley-car, so must the electric motor supplant steam propulsion on the roads in question. Yet in 1876 there was no hint or suggestion of such extended use of electricity on railways—and, in fact, no such applications had been made. On the Intramural road a conductor rail with the ordinary rails for return circuit was used, the current being taken up by sliding shoes bearing on the conductor rail. The motor-car at the head of each train, besides the ordinary seats, was provided with four electric motors, one geared to each axle individually, while the controlling mechanism was arranged so as to connect the motors in single series for starting and to make successive changes passing through intermediate connections until the one having all the motors in parallel was reached, the condition for maximum speed.

This arrangement, with refinements of details especially designed for this work, and first put into full operation at the World's Fair, gave great economy as well as flexibility in the handling of the trains. One of the best illustrations of the progress in the art of electrical engineering in the past few years was the building in the station of the Intramural road of the great direct-coupled continuous-current dynamo of 2,000 h.p. capacity. This machine—by far the largest continuous-current dynamo ever made—was designed by Mr. Horace F. Parshall. It is a comparatively simple undertaking to design and construct very large alternating-current generators, since in many respects they are like duplications or enlargements, simply, of the elements of smaller similar machines. This is not so with continuous-current types, as the problems of armature reaction, air-gap, and self-induction as affecting the working of the commutator at various loads have to be carefully estimated, while the relation of turns on the armature to number of segments in the commutator, the proper proportions and construction of the commutator itself, and the other proportions, have to be studied with great care and adjusted within limits. All this makes the production of so large a machine, built, as it was, without previous experiment, and its parts put together, even to the assembling of the sheet-iron pieces of the armature, in the station itself, a veritable triumph of engineering skill.

Speaking generally, it is not far from the truth to say that at the World's Fair there was as much to be seen of electrical application outside of the Electricity Building as within its walls, though this building was itself a temple of electricity. There were, it is true, a number of exhibits of no special significance, such as those of shifting light in masses of incandescent lamps, obtained by complicated switching appliances, coloured lamps being freely used. The most artistic display of the kind was the Edison tower of lights, a creditable piece of work, the effects obtained from which were certainly very striking and beautiful. The large and varied display of modern electrical apparatus and machinery, together with the various historical exhibits, were of deep interest to the student or engineer. There were found a fully-equipped modern telephone exchange and also Dr. Gray's "telautograph," which is in a certain sense an intended rival of the telephone. There also were found many types of dynamos of various makers both here and abroad. Electric motors were found applied to all manner of work—pumps, hoists, elevators, locomotives, and mining machinery generally. Electric arc lamps and machines, carbons, of all leading makers, were here together with exhibits showing many forms and patterns of incandescent lamp—lamps of low voltage to lamps of high voltage, lamps with one filament to lamps with a dozen filaments, lamps of 1 c.p. to lamps of hundreds of candle-power, etc. There were full lighthouse equipments with their huge compound lenses on view. On the one hand was to be found appliances for generating electricity of enormously high pressures, such as would leap in torrents of sparks over more than 5ft. of clear air space, and, on the other hand, apparatus for electric welding and metal-working capable of yielding currents of 50,000 amperes with pressures as low as two or three volts. The comprehensive exhibit of practical work done in electric welding, including the largest weld ever made by electricity, in which the section at the weld was 48in. of steel, was of great interest to many practical men.

A number of creditable exhibits of alternating-current motors of such types as single-phase, diphase, and triphase construction were found, so that the respective characteristics of this most interesting of the recently-developed forms of alternating-current apparatus could be examined. This class of electric machinery is of so recent production that we must look to the future for its wide application. Everywhere in Electricity Building was evidence of the enormous growth of electrical industries. It could be partly understood from the variety of such things as switches, safety cut-offs, wires, cables, insulating materials, found there, aside from the heavy machinery.

In the department of measuring instruments alone, the progress to be noted was remarkable. Ammeters, voltmeters, wattmeters, recording wattmeters, standard resistances, standard cells, electrical balances and bridges, of the highest degree of excellence, were not wanting. With the refined means of measurement so provided the estimation of electrical forces and quantities may be made with a rapidity and precision hardly equalled in any other department of physical science. Enough has been said, however, to indicate what a harvest has, in the past few years, been the outcome of the earnest effort of brain and hand in the electrical field.

The one discordant note in all this great display of genuine scientific and engineering work was found in the fact that in this same temple of science—in Electricity Building itself—naked imposture, quackery in the form of so-called electric belts, hair-brushes, insoles, and what not, had obtained a footing and stalked forth unabashed. No words of condemnation can be too strong to be applied to the parasites who, in the guise of healing and benefaction, succeed in extracting perhaps the last money from the sick and suffering for their worthless trumpery. The fact that such exhibits were found in 1893 holding place alongside of genuine electro-therapeutic appliances of undoubted merit only heightened by contrast the great shame of their presence.

Within the limits of the present article it has manifestly not been possible to do more than briefly refer to such electrical features of the World's Fair as show in concrete form the great advances which have taken place since the Centennial year.

Our technical schools and universities now devote to the teaching of electricity as a branch of engineering special courses, special laboratories, special instructors. Formerly the little electrical knowledge taught was taken up as a department of physics.

In this present year, the arc lamps in use are numbered by the hundred thousand, incandescent lamps by the million, while millions of passengers are carried daily on electric cars,

Digitized by Google

thousands of horse-power transmitted and distributed by electric motors, thousands of tons of metal refined annually by electrolysis, chemical decomposition on the large scale effected, as in the production of cheap aluminium, electric furnaces are turning out their special products, such as carborundum of diamond-like hardness, and electric welding and metal-working machines are in active service in a large number of manufactures.

In summing up this great growth we must not forget the enormous extension of telephone-service systems in the past few years. So great have been the advances that it is natural to expect that in the immediate future similar rapid and important work will be undertaken and accomplished. It is difficult to play the *rôle* of a prophet unless the prophecies be made so numerous that some of them cannot fail of realisation. There are, however, some things concerning future electrical development about which we can be positive. It is not likely that, except in details, much advance will be made in dynamos and motors. The efficiency of well-designed types is now so high as to leave very small opportunity for improvement. Large dynamos at full load have commercial efficiencies ranging from 95 to 97 per cent. Transforming apparatus of various types may readily have at full load a net efficiency of 97 per cent. The possible efficiency of arc lamps is about reached—and with the incandescent lamp the volatility of carbon at high temperatures governs the efficiency and life. The higher the temperature the more efficient the lamp, the more volatile the carbon of the filament, and the less will be the life of the lamp. It is unlikely that any better material than carbon will be found for the filament, and the properties of carbon as to volatility can probably not be changed.

The cost of these lamps is now about as low as is consistent with good quality and uniformity. The use of transformers for raising or lowering the line potential, permits long-distance transmission of electric energy with moderate loss. The conditions of the most efficient use and operation of electric motors as a source of power when transmitted have been well worked out, so as to leave but little further to be accomplished in that line.

We can hardly expect therefore to make any radical gain in the operation of electric plant unless by the utilisation of new principles in unexplored fields. A substantial gain in the economy of the development of power from fuel is of much greater moment than any possible gain in the efficiency of the electric plant. Hence electricians are looking for cheaper power, as that, and that alone, now means cheap electricity. For the same reason attention is more than ever concentrated on the utilisation of water power, as of Niagara itself by the Cataract Construction Company. Much future work will be done in this field, and it will give rise to many new problems for solution by the electrical engineer. The laboratory work of to-day becomes engineering work of to-morrow. Work which to-day is in the experimental stage reaches its full commercial completeness only after considerable practice with it under varying conditions. The advance work goes steadily on, but in channels which demand more and more intricate knowledge of electric actions. It is the fervent hope of many an electrician that, at no very distant time, the energy of fuel may be converted more directly into electric energy, and without the enormous percentage of loss that is involved in present methods, and that some means may be found to further transmute the electric energy into light with but a small percentage of dark heat, instead of present wasteful methods; but this is still a hope only, and there is not even a probable solution indicated.

In the department of electrical engineering work, the early future will I think witness, in addition to a constantly increasing use of electricity for illumination, further application to chemical and metallurgical work. The field for the application of electricity to mining, for hoists, for pumping, drilling, mine haulage, and the like, is very wide. While it is not probable that the steam locomotive for long-distance railroading will soon be supplanted by electric locomotives, still there is a growing interest in these latter as applicable to special cases, such as specially-designed high-speed roads between populous centres, for tunnel work, and elevated roads in cities. As feeders for trunk lines of railroad it would seem that trolley lines are admirably adapted both for passenger and freight service, and their employment in this way will doubtless become of great importance in densely-peopled localities.

There is also a field for the application of electricity stored in batteries to propulsion of road vehicles—a field in which but little has hitherto been done. Electricity generated under present conditions, involving in the first conversion into mechanical power such an enormous loss of heat energy of the fuel, will evidently not be applied as a general heating agent. In certain cases, in which the disadvantage of high cost may be outweighed by superior advantages of application, as in cooking by electric heat, there may result a considerable extension of its usefulness. But that it can be economically applied simply to heat metal bars for forging in a drop-press or rolling-machine, is not at all to be expected. In special cases of distinctly local heating of metal for welding, bending, or other process, it is now not only used with success and economy, but it would appear that many additional applications of this kind will be made in the future.

While it may be reasonable to look forward to the ability to telephone through an ocean cable under the Atlantic, it is hardly likely that we shall travel over it in ships propelled by electricity. It would indeed be possible to construct electric motors able to turn screws and propel our largest ships, but the supply of current energy to them at the rate of 10 h.p. to 20,000 h.p., for five days continuously, would require a storage battery to be carried such as would be enormously costly and so heavy that it could not be placed aboard without sinking the ship. It should, however, be borne constantly in mind, in dealing with the subject of electrical applications, that a new discovery might at any time change the aspect of every prophecy based on present knowledge and conditions.

HULL.

The advantages of electric traction are gradually being considered by various authorities, and among those who have taken definite steps may be named the Hull Corporation, whose electrical engineer, Mr. A. H. Gibbings, has collected information for the enlightenment of the authority. We cannot give Mr. Gibbings's report in full, as a portion of it consists of extracts from various publications—many, we are glad to see, from our own pages—but we give those portions which will assist our readers to the complete history of the movement in Hull. Thus the committee report:

The Electric Light Committee having received a letter from Mr. Priestly, of Halifax, stating that he wished the committee to visit Halifax and view in operation his system of utilising the steam produced from the heat generated in burning town's refuse, which he claimed would materially economise the production of electricity for lighting, it became the Electric Light Committee's duty, under its function "to watch the progress of electricity in its application to light and power," to investigate this and other letters of a like nature, the result of its considerations being that the chairman was desired to invite Dr. Alderman Fraser, the chairman of the Sanitary Committee (which has control over the refuse destructors), and Mr. Alderman Larard, chairman of the Works Committee (which has management of the tramways negotiations), to meet him and discuss for the benefit of the town the value of co-operation in work on the three subjects of working electricity, refuse destructors, and tramway traction. The chairman of the Electric Light Committee having desired Mr. Gibbings, the borough electrical engineer, to collate all printed matter, letters, and obtain by correspondence any other information important to the consideration of these subjects, the conference of the interested chairmen was held at the electric light office in December, and their report, founded on their discussion (and the report of the electrical engineer, which is printed *in extenso* in the Electric Light Committee minutes for the Council meeting), is hereto appended:

Report to the Electric Light, Works, and Sanitary Committees on Refuse Destructor, Electric Lighting, Traction, and Tramcars worked therefrom.

Having read and duly considered the report of the borough electrical engineer, and the many important letters upon which it is founded, the committee of chairmen above named feel that the utilisation of steam generated by refuse destructors is practical They consider its application is likely to become useful, with or without the aid of coal, in producing electricity cheaper. From its recent rapidly-enlarging practicability of application, it seems that its steam-producing powers may be better applied to the economical charging of accumulator batteries, for the running of self-contained electrical tramways, which system appears to be the best designed for such a town as Hull, with its dock lock-pits and narrow streets, than to electric lighting. In the future they think it could be used economically in some situations in the town to that purpose. Electrical lighting requires a constant generation of heat, which the committee is not certain, without further investigations, these destructors can afford. Electric accumulators for tramway traction may, however, be charged at any time when the heat and steam are available, and used from the cells when and where required. The working of self-contained electrical tramways from the steam produced at town refuse destructors does not seem to have engaged much attention, but the committee feels the constant improvement taking place in these destructors tending to steam generation, and the lightening, combined at the same time with the strengthening and efficiency, of the electric cell plates, as shown in the communications of the Messrs. Epstein, and especially Messrs. Mather and Platt's letter, detailing the improvement in the cells which have been working tramcars successfully for two years in Paris, afford the liveliest hopes that economies in tram traction even now hold out the idea of profitable employment in a town like Hull, which, as the engineer's report points out, would have the benefit over Birmingham of having no gradients to work, and the advantage of economies in steam production from town refuse waste heat, not yet applied for tram traction, which would only

Digitized by Google

entail the cost of plant, and which must economise in the cost of coal.

The committee agree that the matter of making further provision for the destruction of town refuse can, wisely and profitably to the town, be considered together with electric lighting and tramway station centres, for it affords a hope that by the formation of new electric light distributing centres, combining tramway cell charging and refuse destructor, with mortar-mill stations, the three things can be most profitably used to the advantage of the outlying districts of the town as opportunity offers.

The committee think that it would be wise, and much practical information would be obtained, if this was investigated further, and suggest the invitations of Mr. Priestly, Messrs. Babcock and Wilcox, Messrs. Epstein, and Messrs. Mather and Platt, to visit the destructors, steam generators and accumulator cells, and electrical tramways, be accepted; and that a committee, consisting of two members from each of the Electric Lighting, the Works, and the Sanitary Committees, should be nominated for this purpose and to report thereon. They recommend this to their respective committees and the Council in the belief that it will be profitable to the town that these promising systems shall be investigated in operation apart from experts, who are often interested and naturally biased in favour of their own productions.

EVAN FRASER,
Chairman of the Sanitary Committee.
FREDERICK LARARD,
Chairman of the Works Committee.
WILLIAM HOLDER,
Chairman of the Electric Light Committee.

The following extracts are from Mr. Gibbings's report to the committee *v.* pamphlet:

Gentlemen,—I have now pleasure in placing before you the accompanying list of places which are using, or proposing to use, electric tramcars, with the experience, as far as I have been able to ascertain, of those who have had the management of them. You will note, in the first place, that all electric tramway enterprises so far in this country, and all statistics, have been carried out and based upon specially-constructed plant and stations where coal is used as fuel, and no trial has been given to supplying energy in a cheap form from refuse destructors or water power. Also another most important point—namely, that very few districts are so level and flat as the town of Hull, and this will soon make a difference of 50 per cent. in calculating working costs. You will, however, best gain an idea as to the three different systems from the following details attached, and letters from various individuals particularly interested or otherwise. The information with reference to dust and refuse destructors requires very little comment. There should be no difficulty in obtaining exactly what is required, as when once the steam-generating capacity is ascertained, the power obtained may be applied to electric lighting, electric traction, or other purposes.

LIST OF TOWNS WHICH ARE, OR HAVE BEEN, CONNECTED WITH ELECTRIC TRACTION.

Town.	System.	Remarks.
Aberdeen	—	Proposed to run to sea-beach only.
Bradford	Overhead ...	Experimented, but not adopted.
Birmingham	Accumulator	In operation for 12 months.
Blackpool	Underground	Run on sea-front promenade only.
Croydon	Accumulator	Small experiment with two cars only.
Coventry	Overhead ...	No information.
Douglas	—	Proposed electrical railway already running.
Leeds	Overhead ...	In operation two years. Three miles of line in one direction.
Matlock	—	Proposed.
Newport (Mon.)	—	Proposed.
Paris	Accumulator (special patent)	In operation two years. Financed by Messrs. Rothschild and Sons. Very satisfactory results
South Staffordshire	Overhead ...	—
Southport	—	Proposed.

You have now the preceding particulars to go upon, and to make use of in whatever way may suggest itself to you. I think it would be as well, however, to remind you that the information has been obtained in a hurried manner from all sources available, but you have before you for comparison the experience of the users and the statements of the advocates of the various systems. To roughly summarise, we can take each system separately, as follows:

1. *Overhead Wire.*—This is no doubt an economical system, and a comparatively safe one, as no disturbance of the roadway need take place. Still it is liable to great damage from bad weather, and is unsightly. In our particular instance the great difficulty would be in crossing the dock bridges.

2. *Underground System.*—This is the most expensive system in first outlay, and under the stringent regulations proposed by the Board of Trade upon underground traction mains, it would no doubt be a source of expensive maintenance also. Moreover, the same difficulty in crossing the dock bridges would have to be met.

3. *Accumulator System.*—This system appears to me to be the one best suited to the town. The drawback to all electric traction is when used in steep and hilly districts, from which we are peculiarly free, and therefore the strain on accumulators would be steady. Also, this form shows good working results in Birmingham, which is a hilly district, and the system has paid expenses of management, which include large offices with a managerial and secretarial staff. I also think suitable arrangements could be made with a contracting company in order to ensure the venture being a paying one, in any case, say, in 12 months, but there can be no doubt that in the hands of a committee the managerial and working expenses could be so arranged that it would pay the Corporation best to entirely work their own system.

The most important point, however, is the advantage of being able to supply energy in a most economical way from refuse destructors. If refuse destructors were used for either of the other systems, a constant supply of current at a constant pressure would have to be kept up, which would be somewhat difficult at times, but in charging accumulators the night time could often be made available to suit conditions of requirements. Also these destructors could be erected at tramway termini, and very convenient arrangements effected in every way. While these destructors would be in course of erection, the large amount of available energy in the daytime at our central station could be made use of to the advantage of both tramway and electric lighting enterprise.

In conclusion, I have only to point out to the committee that other towns are ready and willing to receive the committee and explain to them the working of systems which have been in operation for some time. The following summarises the advantages over other methods of accumulator traction, combined with the use of refuse destructor and the present electric lighting plant: 1. Much smaller original capital will be required, as there will be no mains to lay in the roadway, nor any rails to electrically connect together at their different lengths. Also, the maximum capacity of the generating plant will be smaller, and therefore cheaper, extending over a greater number of hours in working, which would then, of course, have a higher efficiency than a larger plant working at shorter periods. 2. A less cost of working, instead of increased cost, can be obtained by using double lines throughout, as there will be no stoppages and stand-bys on loop lines for other cars to pass. 3. Accumulators have a higher efficiency on a level road than other methods in places where there are steep gradients, in comparing the three systems in such places. 4. Arrangements for charging batteries can be conveniently made to suit the other demands on the charging station, thereby greatly increasing the efficiency of the charging plant. 5. Total avoidance of the Board of Trade regulations, and consequently less expense in management, which regulations are calculated to impede the progress of electric traction. 6. Smaller plant, fewer instruments, and easier management at the central station. 7. Any breakdown confined to individual cars. 8. One conductor, small cars, quick service, and in consequence easier travelling than on either underground or overhead system. 9. No expensive maintenance. 10. No engineering or electrical difficulties to solve in rounding curves or other obstructions. 11. Smaller capital, hence larger dividend per cent. 12. The losses in charging the batteries compare favourably with losses in the mains of other systems through transmitting steady pressures over a long distance, and also through starting and stopping on other systems, as the regulation of the current with accumulators is not attended with loss through resistances as when current is taken off mains, the regulation being effected by putting more or less cells in series as required. 13. All spare power generated can be utilised for supply of electric light and current in the districts outside of the present area of supply, thus making the destructor plant highly remunerative.

The future of electric trams of which the motive power is accumulators can not only be assured, as seen by the foregoing report, but the above letter [referring to a new type of accumulator, to the particulars required for tender, and mentioning that in France the Rothschilds are interesting themselves in the work] indicates at once the progress which has been made during the past two years, and the general tendency, for obvious reasons, towards this form of traction. The fact of the adoption of this system in Paris, a city where overhead or underground mains would not be tolerated for other reasons than apply in your town, together with the well-known firm who are financing the undertaking, is a large guarantee of its commercial value, and it no doubt forms the latest and best-developed instance of electric self-contained tramcars. I feel this is of the utmost importance, and think it ought to be embodied in the above report, which I could not do in presenting it to your sub-committee, as the matter was not then before me.

ELECTRIC LIGHTING AT FOLKESTONE.

A special meeting of the Folkestone Corporation was held on Wednesday of last week to receive and consider the report of the Electric Lighting Committee.

The **Mayor**, as chairman of the committee, formally moved that the report be received, and Councillor **Payer** seconded the adoption of the report, of which the following is a copy, signed by Councillor Geo. Evan Thompson and Mr. W. G. S. Harrison (the town clerk):

"Your committee was appointed on the 19th of April last to consider and prepare a provisional scheme for the public and private lighting of Folkestone with the electric light, with power to consult an electrical engineer and to pay him a fee for his

Digitized by Google

services not exceeding 50 guineas. Having taken all the necessary steps to obtain reliable information upon such an important and highly technical matter, it has now the pleasure to report as follows: Acting upon the authority conveyed in such resolution, the services of a consulting and electrical engineer—Mr. Mark Parker, of Rochester—were retained for the purpose of advising the committee upon technical and other details. It should, perhaps, be mentioned, for the information of the Corporation, that Mr. Parker is not only an electrician, but is also a practical engineer, and has had some 15 years' experience in electric lighting work, during which time he has designed, constructed, and acted as manager of electricity supply works. In his remarks and in his discussions with your committee he has shown himself thoroughly conversant with all the details in connection with electric lighting, and your committee has also received testimonials testifying to the success of his past work and to his ability to advise the committee upon all matters pertaining to electric lighting. In addition to discussing with the committee the various details involved in providing a supply of electricity, Mr. Parker has presented it with an able and useful report, which, however, is too voluminous to lay before the Corporation, but it may briefly be said that it describes the various systems of electric lighting now in operation, their respective advantages and disadvantages, and being accompanied by diagrams, the entire subject has been presented in a clear and intelligible manner, and your committee has subjected this report to its careful and searching investigation. In addition to this report, three of the members of the committee (Councillors Penfold, Spurgen, and Pursey) have, at their own cost, paid visits of inspection to the following places where installations have been established—viz., North-Eastern Railway at York, House-to-House (West Brompton), Leeds, Hastings, and more especially to the installation of the city of London electrical supply; that installation is being worked on the same principle and lines as that recommended by your committee in this report, and the information obtained by them on such visits has materially aided your committee in their labours. Your committee scarcely think it necessary, specifically, to point out all the advantages of the electric light over that produced from gas and other illuminants. It is doubtless already known to the members of the Corporation that by the use of electricity as the lighting power the air is not vitiated or consumed—the heat given out is only one-twentieth of that radiated by gas; ceilings, decorations, and furniture are not discoloured or injured, great cleanliness is ensured, and in shops and warehouses where valuable or perishable goods are stored it will be highly appreciated, and altogether it is safer and more economical. Your committee will therefore proceed to the other important points—viz., the advisability of its introduction into Folkestone, and the best mode of so doing and working the same.

"(1) As to its advisability.—Your committee is of opinion that there already exists a sufficient demand for the supply to warrant the erection of an electrical installation. Enquiries have been already made by several establishments in the town as to the cost of erecting private installations, and arrangements have also been already made for its actual use in the mansions now being erected on the West Leas.

"(2) As to the powers for carrying out the necessary works.—Your committee is of opinion that it should undoubtedly be carried out by the Corporation, and that it would be extremely prejudicial to the best interests of Folkestone if the Corporation were not to do so, and to allow statutory powers for the purpose to be granted to private undertakers, which will be the probable result if the Corporation decides not to apply for powers or defer proceeding at once with the installation. This must certainly not be done. Your committee, after much discussion, is satisfied and is strongly of opinion that it is undoubtedly advisable to introduce the electric light into Folkestone both for public and private purposes.

"(3) As to the system for adoption.—Your committee has given this point its study and attention, and recommend the adoption of the high-tension alternating-current transforming sub-station system as best suited to the circumstances of Folkestone. This system secures all the advantages of the high and low tension distribution.

"(4) The area of supply.—Your committee advise that the first section shall be confined to the following streets: Sandgate-road, from Town Hall to Earl's-avenue; Church-street, from Town Hall to Priory-gardens; the Leas, from Priory-gardens to Earl's-avenue; Guildhall-street, from Town Hall to Shellons-street; Rendezvous-street, from Town Hall to Tontine-street; Tontine and Harbour streets and Marine Parade to Victoria Pier; the cross-streets from the Town Hall, between the Sandgate-road and the Leas; Castle-hill-avenue to Shorncliffe-road. A plan of this area is annexed hereto showing the exact position of the public lamps and the distribution of mains for the private supply.

"(5) Capacity and cost of plant.—The total capacity of the plant your committee advises should be an installation of 490 kilowatts (a technical expression iu electrical science), 280 of which would be in constant action, and the remainder 210 would form a reserve to meet demands for further supply within the borough as occasion arises for the electric supply. A kilowatt is 1,000 watts A light of 8 c.p. requires 30 watts burning an hour. The capital sum for this plant would amount to £35,000, a detailed estimate of cost, annual working expenses, and probable revenue will be found at the foot of and annexed hereto (estimate No. 4).

"(6) Public lighting.—Two schemes for this purpose have been under the consideration of your committee. No. 1 proposes to use 80 arc lights of 2,000 nominal candle-power placed in the position marked on the plan above referred to. No. 2 proposes a combination of 80 arc lights and 160 incandescent lamps of 25 c.p. each. This method is adopted at Brighton, and is being adopted at Portsmouth, and consists of the attachment of two incandescent lamps to each arc pole, the arc lights being extinguished at 10 or 11 p.m., when the incandescent lamps would be lighted. This system has the advantage over No. 1 as regards cost, being about £200 less per annum than would be the cost of No. 1, but taking all the points into consideration, your committee recommend for adoption the system No. 1. The illuminating power of system No. 1 would be 12 times that at present received from gas, and would cost about £300 more than at present. The illuminating power of system No. 2 would be seven times that at present derived from gas, and would cost about £120 more than at present, but the enormously increased illuminating power is a full compensation for this extra cost. A table showing these comparisons, and the annual cost of gas and each of the above systems, is appended to this report.

"Your committee now begs to conclude with the following recommendations which it submits with confidence for the approval and confirmation of the Corporation.

"1. That the introduction of the electric light into Folkestone should be at once proceeded with, and that it should be undertaken by the Corporation itself.

"2. That the Corporation should in the first instance undertake the supply of electricity under a Board of Trade license, and that application be made forthwith to the Board of Trade for such license under the Electric Lighting Acts of 1882 and 1888, and that the Electric Lighting Committee be authorised to do all that is necessary for that purpose under the advice of the town clerk.

"3. That electric lighting works be established with the necessary plant, machinery, and appliances, and that proper mains be laid under the public streets and thoroughfares in accordance with this report.

"4. That the system of distribution employed be high-tension alternating-current transformer sub-station system, by means of which all the advantages of both high and low tension distribution will be secured.

"For lighting the public lamps arranged in series by means of currents, synchronous commutators should be employed for the purpose of redressing the alternating currents as required.

"5. That the capacity of the plant be 490 kilowatts in accordance with this report and estimate No. 4 attached hereto, 280 of which (as stated above) will be in constant action, and the remainder, 210, will form a reserve to meet demands for future and further supply as the occasion for the electric supply arises.

"6. That the area of supply be in accordance with this report and plan annexed hereto.

"7. That the services of Mr. Parker be retained on terms to be arranged between him and the members of the Electric Lighting Committee (subject to the confirmation of the Corporation) for the purpose of advising and assisting the committee and the town clerk in obtaining the proposed license, in designing the necessary generating and distributing works, in advising the committee with reference to the acceptance of tenders, supervising the construction, and laying down all plant, etc.

"8. That the committee be authorised to instruct Mr. Parker to prepare all plans, specifications, bills of quantities, to obtain tenders for constructing and laying down the proposed work, and thereupon to prepare and submit for the approval of the Corporation such contracts as the committee think advisable for the supply, construction, and erection thereof, and for laying mains under the public streets and thoroughfares.

"9. That the committee be authorised to select a suitable site upon which to erect the proposed electricity generating works, and to negotiate under the advice of the town clerk for the purchase of the same subject to the confirmation of the Corporation.

"10. That upon the license above referred to being granted, the town clerk do immediately apply on behalf of the Corporation to the Local Government Board for sanction to borrow £35,000 for the purpose of the above works, and the result of such application be submitted to the Corporation for confirmation.

"Summary of the financial position under this report, and of the estimated income and expenditure in respect of the area designated in this report and the plan:

Estimated total cost of the generating plant as per estimate No. 4				£35,009	0	0
Estimated income—public lighting	£1,536	0	0			
Private lighting	8,121	0	0			
Total				9,657	0	0
Estimate of working expenses, including coal and other material, salaries and wages, rates and taxes, and incidental expenses	6,192	0	0			
Interest and sinking fund, say, 5½ per cent. on the cost of £35,000	1,925	0	0			
				8,117	0	0
Credit balance, per annum				£1,540	0	0

"We have carefully prepared the above written report from data supplied to the committee during its investigation, and recommend its adoption by the committee."

Various tabulated statements were appended to the report.

A memorial was read from the west end residents of Folkestone petitioning the Corporation to instal the electric light, and urging the necessity of its being done with as little delay as possible. It was signed by 166 persons.

The report was discussed at some length, and its further consideration was adjourned for three weeks, so that some idea of the number of lamps required by private consumers might be obtained,

COMPANIES' MEETINGS.

FOWLER-WARING CABLES COMPANY, LIMITED.

The fifth ordinary general meeting of this Company was held last Friday at the offices of the Company, 32, Victoria-street, Westminster, under the presidency of Mr. Wm. Fowler (chairman of the Company). After Mr. D. Stephen (the secretary) had read the notice convening the meeting,

The **Chairman** moved the adoption of the report and accounts, which were published in our last issue. In doing so he expressed regret that they were unable to pay any dividend, and stated that the directors had on this occasion waived their fees for both past and the present year. Thus they showed their disposition to assist the Company in every possible way, to say nothing of the fact that they had helped the Company by loans made to it. The real cause of the lack of dividend might, he thought, be stated to be the general depression in all businesses during 1893, and to the great competition there had been for orders in the electrical industry. The general condition was so fully set forth in the report that it would be unnecessary to enter into details. The balance-sheet had been very carefully drawn up, and everything had been taken with the intention of showing the shareholders exactly how the matter stood. They had not made out a profit that was not actually made, but showed a genuine one. All they wanted with their admirable factory and machinery of every kind was a larger amount of orders. He thought they might hope that the year before them would be a better year than the last. Another point was that they still required additional working capital. The directors were endeavouring to raise that in a way which they hoped would be satisfactory, but if they did not succeed in that they might again have to appeal to the shareholders for assistance. So far they had obtained practically no help from the shareholders, but he trusted that if it was absolutely necessary they would be willing to come to the aid of the directors. The management of the Company had been extremely able, and his impression was that they could not appoint a better man than they had got. They had every year additional confidence in his management of the Company, his energy, industry, and ability. He hoped with that management they would still make this a successful Company.

Mr. Walter Fletcher, in reference to the remarks made about the depression in trade, said that wherever one travelled new electric systems were being laid down, and he had rather expected some sort of explanation of the want of success on the part of the Company in the face of this enormous increase in electrical work. To an outsider there had never been such a busy time for electrical work, and he was wondering whether the Fowler-Waring cable was the best adapted or whether it was getting superseded by others. If that was so, looking at the balance-sheet, would it not, he suggested, be better to at once wipe off from one side of the sheet "by patents and goodwill, £41,000"? It was only a paper asset. He would like to know something of the turn-over, of which the directors gave the shareholders no idea.

The **Chairman**, in reply, admitted that there was great activity, but there had been depression even in the electrical world. With regard to the turn-over, they did not generally publish particulars, but he would give them the figures privately after the meeting. The turn-over last year was considerably greater than in the previous year, but the profit was not so large proportionately, the reason being that, owing to competition, the estimates had to be made on a less profitable scale than in former years. Concerning the suggested reduction of capital, it would be necessary for that to go to the court, and that would be objectionable, and would tend to affect the credit of the company. He then called upon

Mr. Alfred E. Mavor, the general manager, who referred to the presidential address of Mr. A. Siemens delivered the previous evening, and which showed clearly the reasons why electrical enterprise had been kept back and hampered by many causes. During the latter months of 1893 business had been recovering, and it might be as well for them to know that the Company were disturbing the streets and laying mains in London and other towns. He had absolute confidence that their cables held the very first position. He would not say that there were no other cables so good, but comparative trials had demonstrated that they were in the first rank as cable-makers. It was impossible to say whether the asset of £41,000 was too large or too small, and he did not think that that sum would appear a very large amount for the ultimate goodwill of the Company. He thought they were thoroughly in a position to compete with the greatest of their rivals, and so far as they had gone they had equalled some of the best of their work.

The motion for the adoption of the report and accounts, seconded by **Lord Medway**, was then put and carried. The Lord Medway and Mr. Geo. F. Smart, the retiring directors, were re-elected, and Messrs. Cooper Bros. and Co., the auditors, were reappointed.

BUSINESS NOTES.

Llandrindod.—This town is considering the question of going in for the electric light.

Western and Brazilian Telegraph Company.—The receipts for the week ended January 12 were £3,297.

Porthcawl.—The Porthcawl Local Board on Monday decided to light the streets with gas, in preference to electric lighting.

Liverpool Overhead Railway Company.—The traffic receipts of this railway for the week ending 14th inst. amounted to £665.

West India and Panama Telegraph Company.—The receipts for the two weeks ended January 15 were £233 less than for the corresponding period of 1893.

Accepted Tender.—The tender of Mr. H. Willcock, of Wolverhampton, at £4,985, has been accepted by the Wolverhampton Corporation for the erection of an electric light station.

St. James's and Pall Mall Electric Light Company.—The directors recommend a dividend at the rate of 4½ per cent. per annum on the ordinary shares for the year ending December 31, 1893.

Coventry.—The Town Council on Tuesday authorised the corporate seal to be affixed to an agreement between the Corporation, Mr. W. S. Graff Baker, and the Coventry Electric Tramways, Limited.

Wakefield.—The Town Council have refused the application of Mr. S. C. Gloyne for permission to lay a 2in. diameter iron pipe to carry an electric cable across Market-place from his shop to Mr. Winder's shop opposite.

Electric Exploitation Company, Limited.—This Company has been registered with a capital of £25,000 in £1 shares, to acquire certain patents relating to the generation and application of electricity, and to develop the same.

Radcliffe.—Mr. F. F. Bennett, M.I.E.E., of Messrs. Bennett and Druce, Preston, has been instructed by the Radcliffe local authorities to draw up a report and estimates, and recommend a system of electric lighting for that district.

Coatbridge.—The Town Council have referred to the Electric Light Committee a request from Mr. A. Paterson for permission to place an overhead wire between his two shops in Main-street, in connection with his installation of the electric light.

Tenders Required for Hanley.—Tenders are invited by the 29th inst. for the electric light wiring and fittings to the Corporation buildings. Specifications, plans, and particulars may be obtained from Mr. Joseph Lobley, borough engineer, Town Hall, Hanley.

Aberdeen.—The Gas Committee of the Town Council have settled the rates to be charged for electric meters. The charges will vary from 5s. to 30s. per quarter. It is expected that the meter that will be most commonly used will be the one on which the rate is 7s. 6d. per quarter.

Leamington.—The Town Council have decided to introduce telephonic communication between the office of the National Telephone Company and the police station at the old town hall. Specifications are to be prepared and advertisements issued for tenders to carry out the work.

Situations Vacant.—The Corporation of Wolverhampton invite, by the 27th inst., applications for the post of draughtsman and assistant in the borough electrical engineer's office, at a salary of £90 per annum; also for the post of working outdoor foreman and linesman, at a salary of £2 per week.

Ramsbottom.—The Electric Light Committee of the Local Board, having considered a scheme for supply of electric light for the district, and having regard to the necessity of obtaining a provisional order therefor, have adjourned the matter for further consideration. More information is to be sought.

City and South London Railway.—The receipts of the Company for the week ending January 14 were £951, against £1,008 for the same period last year, or a decrease of £57. The total receipts for the first half-year of 1894 show a decrease of £65 compared with those for the corresponding period of 1893.

Office-Lighting.—Messrs. E. P. Allam and Co., of 49, Finsbury-pavement, inform us they have recently completed the electric lighting of the extensive offices and sample-rooms of the Mazawattee Tea Company in Eastcheap, and are now engaged, among other work, in wiring 50, Bedford-square for Mr. A. Leveson.

Anglo-American Telegraph Company.—Balance dividends of 13s. 6d. per cent. on the ordinary stock and of £1. 7s. per cent. on the preferred stock are recommended by the Board, making total payments of £2. 11s. per cent. and £5. 2s. per cent. respectively for the year 1893. The sum of £844 remains to be carried over.

Eastern Telegraph Debentures.—The Eastern Telegraph Company notify that the coupons on their 5 per cent. debentures, due February 1 next, will be paid on and after that date at Messrs. Glyn, Mills, Currie, and Co.'s bank, 67, Lombard-street, E.C. Coupons should be left at the bank three clear days for examination.

Tenders Wanted for Cheltenham.—The Corporation invite tenders by the 23rd inst. for supplying and erecting engines, dynamos, and boilers at their electric light station. A copy of the specification and any further information may be obtained on application to Mr. Joseph Hall, A.M.I.C.E., Municipal Offices, Cheltenham.

Issue of Debentures.—Messrs. Robey and Co., Limited, announce the issue at par of £125,000 4½ per cent. first mortgage debentures, secured by a first mortgage on the freehold engineering works at Lincoln, and also forming a floating charge on all the other property of the company. Applications will be received by the Lincoln and Lindsey Bank, and Messrs. Prescott, Dimsdale, Cave, Tugwell, and Co. up to four o'clock this (Friday) afternoon.

Dover.—The Mayor mentioned at a meeting of the Town Council last week that the Electricity Supply Company hoped shortly to give an exhibition in the Town Hall. It would be necessary to carry wires into the hall, and it was suggested that they might as well be permanently fixed. It was decided to have

Digitized by Google

the wires fixed permanently if the company would do the work, and wait till the electric light was adopted in the hall before making the charge.

Walsall.—The Town Council last week adopted the report of the General Purposes Committee, who recommended that the portion of the Wolverhampton-street Gasworks, shown on the plan prepared by the borough surveyor, should be appropriated as a site for the proposed electric generating station; and that the application of the Council for the sanction of the Local Government Board for a loan of £19,650 for the proposed scheme of electric lighting be increased to £22,000.

Canterbury.—The Town Clerk mentioned last week, at a meeting of the General Purposes Committee, that he was in a difficulty with regard to the electric light. As long ago as September he had the order to affix the Corporation seal, but he could not get the company to execute the deeds on their part. He had written time after time. Mr. Harris enquired whether the town clerk had got the transfer money. The Town Clerk replied that he only had £35 of it. The matter then dropped.

City and South London Railway Company.—The accounts for the past half-year show a balance, after providing for the debenture interest and the full dividend on the 5 per cent. preference shares, sufficient to allow the payment of a dividend on the consolidated ordinary stock at the rate of ⅝ per cent. per annum, against a dividend at the same rate for the corresponding period last year, leaving a balance of £1,064 to be carried forward to the next account, as against £822 for the same period last year.

Aluminium Company.—Mr. Justice Wright has made an order for the reduction of the capital of the Aluminium Company from £400,000 to £80,000. At the time the Company bought the patents under which they manufacture aluminium the cost of manufacture was 60s. a pound. These patents, it was said, were now useless, as other electrical discoveries had caused the same metal to be produced at 2s. 6d. a pound. The Company, having lost so large an amount of capital, passed a resolution reducing the £5 shares to £1, and it was this resolution Mr. Justice Wright has confirmed.

Keighley.—The Gas Committee of the Corporation have lately been making enquiries into the electric lighting system in operation at several places. The members, accompanied by the Mayor, have visited the House-to-House Company's electric lighting station in Leeds, and the Bradford Corporation's electric lighting station. The committee have also inspected a new patent boiler and furnace for producing steam from refuse, with a view to applying the steam to electric purposes. Arrangements have been made for visiting Morecambe and other places where different systems are in operation.

Peterborough.—Various private installations have been put up in this town, and now Messrs. Barford and Perkins, of the Queen-street Ironworks, have laid down an installation entirely by their own workmen, under the superintendence of Mr. J. Perkins, A.M.I.C.E. The motive power in this case is available from one of the steam-engines for driving other machinery in the works. The installation comprises a dynamo capable of an output of 50 amperes at 110 volts. The lights consist of incandescent lamps of 16 c.p. in the offices, and four large arc lights of 1,000 c.p. It is intended to instal additional arc and incandescent lamps in other parts of the works.

Direct Cable Company.—The report of the Direct United States Cable Company, Limited, for six months ended December 31 shows that the half-year's revenue, after deducting outpayments, amounted to £41,051, as compared with £43,629. The working and other expenses, including income tax, amounted to £19,059, leaving a net balance of £21,992, making, with £819 brought forward, £22,811. For the corresponding period of 1892 the working expenses and other payments amounted to £18,982. Interim dividends of 3s. 6d. per share for the quarter ended September 30, 1893 (paid October 24, 1893), and of 3s. per share for the quarter ended December 31, 1893 (payable January 24, 1894), have been declared, and the balance of £3,080 has been carried forward.

Accrington.—Mr. Riley moved, at a meeting of the Town Council, that a committee should be formed for the purpose of carrying out the electric light scheme, but it was pointed out that that was not the proper time to make such a resolution. Mr. Eli Higham said the matter had been in the hands of the Legal and Parliamentary Committee, but it had been very difficult to consider the subject. He certainly thought something should be done. If they intended to have the light for next winter for the centre of the town, they ought to take some steps, and Mr. Riley was quite justified in bringing the matter before the Council. If they did not intend to move in the matter, he thought they ought to let it be clearly understood, as he was quite sure outsiders would come in unless the Council did something. They were not doing justice to Mr. Shoolbred or the ratepayers.

Lighting at Aberdeen.—The Finance Committee on Monday laid before the Town Council a report by the city architect, superintendent of gasworks, and electrical engineer upon the cost of lighting the various departments of the municipal buildings. The installation, the report says, should be divided into four different departments: (1) The municipal department, consisting of 85 lights; (2) police and gas department, consisting of 32 lights; (3) sanitary department, consisting of 15 lights; (4) surveyor's department, consisting of 33 lights—a total of 165 lights. The cost of lighting the various departments, including fittings, is estimated as under: Municipal department, £145; gas and police department, £52; sanitary department, £27; surveyor's department, £46—a total cost of £270. The Council approved of the report, and authorised the electrical engineer (Mr. Murray) to prepare the requisite specification and invite tenders.

Taunton.—The Electric Lighting Committee of the Town Council last week reported that the borough surveyor and Mr. Couzens had been to London and had an interview with Dr. Fleming as to the proposed extension of the works. The committee said that owing to the burning out of an armature it was found necessary to procure one from Messrs. Laing, Wharton, and Down; their price was £55, and the committee recommended that it be purchased, and that the one which had broken down be repaired by Messrs. Newton. The committee stated that 33 small meters were required at once, and they had ordered that a sample meter be forwarded by Messrs. Laing, Wharton, and Down to Dr. Fleming, and if he approved thereof, that three dozen be ordered. The committee reported that there was not sufficient old wire in stock to carry the light to Osborne House, and they recommended that the wire be purchased. After some discussion the report was adopted.

Great Yarmouth.—The following tenders were received for the erection of electric lighting central station for the Corporation:

M. Barnard	£3,656 0 0
R. Eastoe	3,346 17 0
G. T. Flaxman	3,124 10 0
T. Howes	3,093 0 0

Carter and Wright	2,817 0 0
F. Grimble	2,800 0 0
G. W. Beech	2,768 10 0
J. F. W. Bray	2,626 0 0
W. Cork	2,510 0 0
J. W. Rand	2,485 0 0

The tender of Mr. Rand having been withdrawn, that of Mr. Bray was accepted.

Electric Lighting in Edinburgh.—The sub-committee of the Edinburgh Town Council in charge of the matter of electric lighting in the city at a meeting this week, accepted an estimate for the removal of the buildings on the site of the proposed supply station to be erected at Torphichen-street, and generally approved of the plans for the station submitted by the burgh engineer. The plans show a building of considerable extent. Provision is made for the delivery of coal direct from the railway in the truck, and it is intended, when coal has to be stored, to run the wagons within the building, and by hydraulic machinery to hoist them to the level of the store and "tip" them over. In this way the work of delivery will be expeditiously overtaken. The engines and dynamos will be accommodated in the central part of the building facing Dewar-place, while on the same side of the station will be the plant for the arc lighting. As the matter is one of urgency, the Corporation requiring to be in a position to supply electric light to consumers in eight months' time, the work of clearing the site will be commenced at once.

Shoreditch.—The Dusting and Scavenging Committee of the Shoreditch Vestry have reported that, from the experience of other authorities, it appeared that dust refuse could be destroyed by fire at about £3,500 a year, and, in view of the saving that would thus be effected in this department, the committee felt that the time had arrived when a dust destructor should be provided. They therefore recommended the Vestry to take the necessary steps to provide for the destruction of dry refuse by a dust destructor. The report was adopted, and, in connection with this matter, a report from the Electric Light Committee was read from Messrs. Manlove, Alliott, and Co. on the question of the production of heat by dust destruction. The report showed that the annual saving from the present system, after crediting the value of steam sold for electric lighting purposes as a separate undertaking, would amount to £4,330 per annum. The committee reported that they had further considered the question of site, and were of opinion that the Pitfield site was the best for all these purposes. The price the committee proposed to offer was £33,500. The report was carried.

Barnet.—The Electric Light Committee of the Local Board reported last week that no tenders had been received in answer to advertisements for lighting the town, and that there was nothing before it to show that the electric light could be supplied to the town upon a satisfactory commercial basis. Mr. James said that although nobody had responded to the invitation to send in tenders, the committee ought not to quite close its efforts. The object of the Board in referring the question to the committee was to ascertain the best mode of lighting the town by electricity. He moved it be an instruction to the committee to further pursue its enquiries. Mr. Clark seconded the motion. Mr. Morse said the fact that a company had not come forward to undertake the scheme caused the committee to feel strongly that the companies did not regard Barnet as a favourable town for lighting. Personally, he was most anxious to have the electric light if it could be obtained at a reasonable cost. What he would suggest was that the Board should empower the committee to spend about £10 in getting from a good man a report as to whether it was advisable to have electricity in the town. The motion, with the addition of Mr. Morse's suggestion, was adopted.

Tenders Required for Edinburgh.—The Corporation invite tenders for the following work in connection with their electric lighting station in Torphichen-street, Edinburgh: Contract No. 1. Boilers (dryback marine type) and mechanical stokers. No. 2. Engines (Willans), dynamos, pipes, etc. No. 3. Switchboard instruments and connections. No. 4. Storage batteries. In contract No. 2 it is a condition that the dynamo-makers must have already constructed dynamos of at least 100 units capacity. Copies of any of the specifications can be obtained on written application

Digitized by Google

from the Town Clerk. All information will be supplied by Prof. A. B. W. Kennedy, 14, Old Queen-street, Westminster, S.W. Firms wishing to obtain copies of any of the specifications must send with their written application a deposit of two guineas for one specification, or three guineas for any larger number; the deposit will be returned on receipt of *bonâ fide* tenders. Tenders are to be directed to the Town Clerk, and enclosed separately in sealed envelopes, marked "Electric Lighting—Tender for Contract No. —." Tenders will only be considered from firms who are actually manufacturers of the whole or an important part of the work for which they estimate. They must be received in Edinburgh not later than Tuesday, the 30th inst.

The Newport Tenders.—"Motor," writing to a Cardiff paper on this subject, says: "Before committing the Council to an outlay of £2,595 more than the lowest tender, every detail should be rigorously exhausted and the figures fully analysed. Take the two reasons assigned for accepting the higher tender: 1. 'The committee have visited works done by Messrs. Fowler and Co.' Have they visited any works done by Messrs. Crompton and Co.? 2. The engineer stated that 'Messrs. Crompton and Co. have carried out works on the low-tension system.' Does this disqualify them for the high-tension system? If Messrs. Crompton and Co. are capable and competent to carry out the works in accordance with the Council's requirements, and willing to comply with the provisions and conditions stipulated for the installation, why should not the town benefit to the extent of the difference in the two tenders—£2,595? It might appear from the engineer's explanation that it is a choice between two systems. In that case the Council could not do better than adopt the best, even at the first cost of greater capital outlay; but if it is not a choice of systems, but of one out of two competent contractors, and if both are prepared to adhere to the prescribed conditions and terms and willing to undertake the work in accordance with the specification (and there ought to be no difficulty in ascertaining this), the committee would not then hesitate to recommend the acceptance of the lowest of the two tenders and, in addition to the saving of £2,595, secure the advantage of a large portion of the contract sum being circulated amongst the working population by the machinery being made at Newport, as it appears would be the case if Messrs. Crompton and Co. secured the contract."

The Manchester Edison-Swan Company's Showrooms.—The showrooms which the Manchester Edison-Swan Company, well known in that city in connection with electric lighting, have recently built, are very interesting and attractive. To the passer-by only one of the showrooms is visible, and the impression given is that this is the full extent of the premises. But let the visitor enter, and surprises will be in store for him. He is led down, apparently to the bowels of the earth, but instead of arriving at vaults he enters a sort of Aladdin's palace, brilliant with electric light. Besides the ordinary showrooms the Company have fitted up a complete suit of model rooms, beautifully furnished, and arranged with every variety of style of electric light fitting. The object of this is that their clients may see the actual effect the fittings they are selecting will have in private rooms. A special feature is made of electroliers of cut crystal glass and gilt metal-work, most tastefully arranged—a combination which seems perfectly suited to show the electric light to full advantage. Among a number of beautiful designs in this style is a large electrolier, the general lines of which follow the curves taken by water falling from a fountain, the sparkling crystal lending itself very happily to this effect. Besides the drawing, dining rooms, etc., there is a large and handsome billiard-room with a new arrangement for lighting the table, which is a distinct improvement on the old style. Those visitors who take an interest in the engineering part of electric lighting are given an opportunity of examining the generating plant which produces the current needed for the different showrooms, both gas and steam power being employed. Thus those who think of having the light installed in their country houses can see both systems at work, and judge for themselves which would be the more suitable for their purpose. Taken altogether, the show is a very fine one, and those near Manchester thinking of fitting up their houses would find it advantageous to make an inspection of these showrooms before doing so.

Lighting at Aberdare.—The Local Board have this week considered an application to assent to the provisional order sought by Messrs. Gery and Rhys, on behalf of Messrs. J. C. Howell and Co., for the lighting of a portion of the town. The Chairman pointed out that the company only sought for power to light Canon-street, a portion of High-street, Commercial-place, Commercial-street, Cross-street, and Cardiff-street at present, and that the whole of their power only extended to half a mile from St. Elvan's Church. He also noticed they asked for power to charge 8d. per unit, while in Pontypool they only charged 6d. per unit. Mr. P. T. Rhys, solicitor to the promoters, and Mr. J. C. Howell, one of the directors of Messrs. J. C. Howell and Co., were admitted into the room, and, in answer to the questions of the chairman, said the only reason why the application was made in their name was that they had no time to form a local company, but that they intended to form a local company as soon as possible. He also explained that the 8d. per unit was a maximum charge, and no doubt they would reduce this. There was power in the provisional order to transfer the powers to a company when formed. Mr. D. P. Davies said he thought the order sought for was very objectionable. It was not a local company, and its charges were too high. Another and a very strong objection was that it only provided for a very small portion of the town. He would therefore move that the Board should refuse to grant its assent. The chairman said he feared as Mr. Davis was a shareholder in the gas company he was disqualified to to vote, and the clerk said he thought it was so. Mr. R. Llewellyn moved, and Mr. W. Little seconded, that the Board should assent. The Chairman said he would have to vote against that on the ground that the order asked for was so limited. Had they asked for power to light Aberaman and Trecynon as well as the town he would probably support it; but he felt the present proposal would only keep back a far better scheme. A division being taken, four voted in favour of assent being granted and two against.

Lighting of Windsor.—At a meeting of the Town Council last week, a letter from Messrs. C. A. Parsons and Co., the Fowler-Waring Cables Company, and Mr. A. A. C. Swinton, to the following effect was read: "You are perhaps aware that negotiations are in progress between the liquidator of the Windsor and Eton Electric Light Company, Limited, and ourselves, with the object of our making the necessary arrangements for enabling the company to resume its business in a manner which will be satisfactory to the local authority and the public. We therefore beg to inform you that we propose to lay down a central station in Windsor, with entirely new plant, for the supply of 10 000 8-c.p. lamps, the generating plant to be manufactured by Messrs. C. A. Parsons and Co., of Heaton Works, Newcastle-on-Tyne, and to be similar to those supplied by the supply companies at Newcastle-on-Tyne, Scarborough, and Cambridge, where they are in very successful operation. The mains to be supplied by the Fowler-Waring Cables Company, and to be similar to those supplied by them to the London Electric Lighting Company, Limited, the City of London Electric Lighting Company, Limited, and the Corporations of Exeter, Brighton, etc. The system to be the high-tension alternating at 2,000 volts, transforming into 100 volts before reaching the consumers' terminals. We would propose to sell or dispose of the present central-station site, and to apply to your Corporation for the sale or a lease of land and water power on the Corporation property at the waterworks. We believe that the contemplated arrangements would involve an expenditure of £15,000, and that the light could be supplied within six months from the date of an order of the court allowing the company to resume its business. We shall be much obliged if you will bring this letter before the Electric Lighting Committee at their next meeting, and we shall be pleased to attend that or any subsequent meeting to give further explanation that may be required." The Deputy Town Clerk said the letter had been laid before the Waterworks Committee, who had directed the town clerk to write to the Board of Trade to ascertain the position of the late electric light company. He had received a reply stating that the order had not been revoked, and that it did not appear to contain any provision for the transfer of the powers, duties, and obligations of the undertakers to any other company or person. The Deputy Town Clerk, continuing, said some communications were made to the Mayor, who made arrangements for the gentlemen to meet the Waterworks Committee, which they did. It appeared from what was said that the present works were wholly useless, and it would be necessary for new wires to be laid down altogether. The Mayor suggested that the matter be referred to a committee, which would be composed of those members who were not interested in either electricity or gas. Councillor Soundy moved that such a committee be formed, and this was agreed to.

Fleetwood.—The clerk to the Improvement Commissioners has been authorised to advertise for applications for the position of resident working electrical engineer in connection with the electric lighting station. A public meeting of ratepayers, convened by the chairman of the Commissioners (Mr. J. F. Marginson), to consider the proposal to light the town by electricity was held at the Free Library last week. Mr. Marginson presided, and most of the members of the Commissioners occupied seats on the platform, together with Mr. J. Tildsley (the clerk and accountant) and Mr. Dawbarn (the representative of the Brush Electrical Engineering Company, whose tender had been accepted). Mr. D. W. Dickinson moved a resolution approving of the action of the Commissioners with reference to the proposed installation of electric lighting. Mr. J. Smyth seconded. Mr. Dawbarn, who was asked to explain the electric light scheme, pointed out to pause further, as Mr. Drewry suggested, would be a serious step, as they had had their provisional order renewed four times. If the order was not again renewed, the effect would be that any enterprising company might succeed in establishing works at Fleetwood, and the Board of Trade would say that in common fairness they must let the private enterprise take its course. At Fleetwood they had one exceptional advantage, and that was they would not be called upon to take the electric light as a luxury, but they would be able to save a considerable sum per annum as compared with their present gas bill. He had prepared an estimate of the working cost with the present plant. The expenses for maintaining the present plant, assuming it would maintain the 232 street lamps of 32 c.p., and 5,900 incandescent lamps of 8 c.p. in private houses, works, etc., for material, fuel, lamp renewals, salary of the engineer, wages of his staff, etc., amounted to £966. 11s. To this they had added £100 for incidentals. They had also added for the machinery, the conductors in the streets, and the whole apparatus, including the station buildings. That sum amounted to £503, bringing the total to £1,570. There was then the interest on the capital outlay, and the setting aside of a sufficient sum to liquidate that outlay in a term of years. For this he had taken £600, bringing the total expenditure per annum to £2,170. The question had been asked, What would be the cost of street-lighting? They were now lighting 200 street lamps at a cost of £270 per annum. These lamps are only 8 c.p. each, and the result was their streets were really badly lighted, and did not

Digitized by Google

compare favourably with any town of the same size. They could not expect to get 32-c.p. lamps and 15 per cent. more of them, with 10 per cent. longer time of burning, for the same money, but they would agree the sum of £371. 18s was an exceedingly good result for such a vast increase. The second item of the revenue would be from private consumers. He was not in a position to pledge the Board, and he did not know whether they would finally adopt the figure he had assumed, but he thought they would view favourably the proposal to charge 12s. per lamp of 8 c.p. per annum. That would bring in a revenue, for 5,900 lamps installed, of £3,540, which, added to the public lighting, amounted to £3,911. 18s. The total expenses, including interest, amounted to £2,170, leaving £1,740 as natural profit, which would doubtless go towards further reduction—either by giving the street-lighting free or still further reducing the cost to the private consumers. He believed the Board would be quite willing to charge by meter at 6d. or 7d. per unit. That corresponded to gas at something like 3s. 6d. per 1,000. At 4s. per 1,000 a 10-candle gas lamp would cost £1 for every 1,000 hours burning, whilst electricity at 6d. per unit, for the same light and the same time would cost 15s. To the latter must be added the cost of lamp renewals. They lasted about 1,000 hours, and cost about 1s. 6d., so that the total would be 16s. 6d. against £1. The Commissioners fully believed 12s. per lamp was lower than that basis. In London the cost of putting the light in offices was as low as £1. If the Commissioners kept that work in their own hands they would be in a position to give low prices, because they would not want profit. He thought they would be able to instal lights in private houses at about £1, and in shops at 17s. or 18s. After some discussion the resolution was put to the meeting and carried.

PROVISIONAL PATENTS, 1894.

JANUARY 8.

382. **Improvements in secondary batteries.** Henry Capel Lofft Holden, The Eves, Belvedere, Kent.

433. **An improved electric switch.** Chaimsonovitz Prosper Elieson, 4, South-street, Finsbury, London.

439. **Improvements in girder clamps and hangers for supporting pipes, electric conductors, and the like.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Charles MacTaggart and Francis McKernan, United States.)

JANUARY 9.

444. **Improvements in electric light fittings.** Charles Spencer Northcote and John Benjamin Verity, Plume Works, Aston, Birmingham.

454. **Improvements in the generation and distribution of the electric current.** William Ealdred, 5, Brightside-bank, Brightside, Sheffield.

455. **Improvements in incandescent lamp shades.** Edward Dean Cook, 70, Wellington-street, Glasgow. (Complete specification.)

484. **Improvements in electrical alarum clocks.** Joseph Coshigan, 97, Newgate-street, London.

489. **Improvements in electrical clocks.** Ernest Herbert, 11, Southampton-buildings, Chancery-lane, London.

493. **Improvements in safety cut-outs specially applicable for trolley wires of overhead electric railways.** Alfred Julius Boult, 325, High Holborn, London. (Melancthon Hanford, United States.)

494. **Improvements in forges or furnaces for heating or working metals electrically.** William Phillips Thompson, 6, Lord-street, Liverpool. Charles Lewis Coffin, United States.) (Complete specification.)

495. **Improvements in transformers or converters for electric currents.** William Phillips Thompson, 6, Lord-street, Liverpool. (Charles Lewis Coffin, United States.) (Complete specification.)

496. **Improvements in apparatus for heating or welding metals electrically.** William Phillips Thompson, 6, Lord-street, Liverpool. (Charles Lewis Coffin, United States.) (Complete specification.)

513. **Improvements in or relating to apparatus for the production and distribution of electricity.** George Joseph Philpott and Robert Hammond, 46, Lincoln's-inn-fields, London.

524. **Automatic switch for accumulator charging.** Robert William Peacock Robertson, Charing Cross, London.

JANUARY 10.

526. **Improvements in electric brushes.** Edward Lewis Levetus, 7, Cherry-street, Birmingham.

546. **Improvements in electric telephony.** Alexander Muirhead and George William Green, 124, Chancery-lane, London.

548. **Improvements in or appertaining to working quadruplex and duplex telegraph signal-receiving instruments.** William Phillips Thompson, 6, Lord-street, Liverpool. (William Francis Melhuish, India.)

JANUARY 11.

646. **Improvements in primary voltaic batteries.** William Walker, jun., Frank Richard Wilkins, and Jabez Lones, 7, Staple-inn, London.

660. **Improvements in guards for electric and other lamps.** James Eaton-Shore, 77, Chancery-lane, London.

653. **Improved means for arranging and intensifying the magnetic fields of dynamo-electric machinery.** James William Thomas Cadett, 33, Southampton-buildings, Chancery-lane, London.

654. **Improvements in electrically-illuminated advertising signs.** Guy Carey Fricker, 15, Spencer-road, Putney, London.

666. **Improvements in holders for incandescent electric lamps.** John Birnie Clayton Evans, 4, South-street, Finsbury, London.

669. **Improvements in electric batteries.** Charlton James Wollaston, 47, Lincoln's-inn-fields, London.

670. **Improvements in the manufacture of electrodes and use of the same.** Arnold Philip, 43, Onslow-road, Richmond, Surrey.

JANUARY 12.

689. **Improvements in the application of incandescent lamps for use as nightlights** Alexander William Stewart, The Crescent, Dalmuir, Dumbartonshire.

690. **Improvements in electric apparatus for signalling on railways.** Robert Stuart Hampson, 17, St. Ann's-square, Manchester.

722. **Improved electrical marine engine governor.** George Leonard Addenbrooke, 433, Strand, London. (R. Macdonald, Australia.)

764. **Improvements in jointing and connecting electric cables.** George Hinde Nisbett, 248, Stanstead-road, Forest Hill, London.

JANUARY 13.

791. **A combination door-bolt and electric switch.** John Joseph Wilson, 21, Croydon-grove, Croydon.

835. **Improvements in the construction of electrolytic apparatus, and in the application thereof in oxidising, chlorinating, and analogous processes.** James Hargreaves and Thomas Bird, 191, Fleet-street, London.

836. **Improved means for obtaining metallic bases and their compounds by electrolysis.** James Hargreaves and Thomas Bird, 191, Fleet-street, London.

SPECIFICATIONS PUBLISHED.

1889.

1480. **Electric meters and motors.** Alderton. (Second edition.)

7719. **Electric or galvanic elements or cells.** Schoop. (Second edition.)

19554. **Alternating-current generators, etc.** Von Dolivo-Dobrowolsky and others. (Second edition.)

1892.

23101B. **Galvanic batteries.** C. A. J. H. and H. E. R. Schroeder.

23773. **Electric smelting.** Niewerth.

1893.

562. **Electric measuring instruments.** Goolden and Evershed.

933. **Electrical arc lamps.** Lauder.

NOTES.

Acton. — The question of extending the telephone system to Acton is under consideration.

Skates.—A German electrician is reported to have adapted the incandescent lamp to the points of skates.

Folkestone.—The Town Council will further consider the report of the Electric Light Committee on the 13th proximo.

Newcastle.—As in other towns, so in Newcastle is the use of the electric light causing an increase in the consumption of gas.

Clock-Lighting.—It is suggested that the clock in the turret of the new Yorkshire Penny Bank at Bradford should be lighted by electricity.

Shiplighting.—The "Berlin" and the "Amsterdam," recently launched at Hull for the Great Eastern Railway Company, are to be lighted by electricity.

Conversazione.—The annual soirée and conversazione of the Bradford Scientific Association took place on Tuesday evening in the society's rooms, Sunbridge-road.

Condensing Plant.—Messrs. W. H. Allen and Co., of Lambeth, S.E., have forwarded us a copy of their illustrated catalogue of condensing plant suitable for electric light installations.

Telephony.—The Gas Committee of the Leeds Corporation have decided to have telephonic communication established with the different gasworks through the central telephonic exchange.

The Working of the Telegraph System.—The commission from St. Martin's-le-Grand appointed to enquire into the working of the telegraphs over the country, has this week visited Glasgow.

Tunbridge Wells.—The Local Government Board have sanctioned the application made by the Tunbridge Wells Corporation to spend £13,000 on electric lighting in the principal streets of that town.

The Taunton Case.—Mr. H. E. Hunt, until recently manager and engineer of the Taunton electric light works, has been sentenced to 12 months' imprisonment for forging two promissory notes for about £300.

The Patent Office.—A new series of illustrated abridgment classes will shortly be issued by the Patent Office. Abridgments have been completed referring to specifications for the period 1877-1883.

Electric Traction on Railways.—An electric locomotive has been tried on the railway between Havre and Paris. It was attached to a train of 13 carriages, and is said to have attained a speed of 75 miles an hour.

Dr. Tibbits's Action.—In the action brought by Dr. Herbert Tibbits to recover damages for an alleged libel published in the *Charity Record*, the jury returned a verdict for the defendant, and judgment was accordingly given to that effect.

Personal.—We understand that Mr. W. B. Esson will join the well-known firm of Messrs. Johnson and Phillips, Charlton, on February 1 as manager of the electric light, electric transmission of power, and electro-chemical departments.

The Leeds Tramways.—The Leeds town clerk has received a communication from the Board of Trade, who sanction the borrowing by the Corporation of £130,000 for the purchase of the undertaking of the Leeds Tramways Company under the provisions of the Tramways Act.

New French Cable.—A new French submarine cable is about to be laid in the Red Sea. It crosses the Bay of Jibuteel, placing Obock in communication with Jibuteel (or Djiboutil), which is to be the new seat of government of the French colony. The cable is 31½ nautical miles in length.

Transmission of Power in Russia.—A German syndicate is stated, by a telegraphic news agency, to have secured a concession from the Russian Government for the erection of gigantic electric power works for the purpose of transmitting electrical energy from the famous Imatra waterfalls in Finland to St. Petersburg.

The "Medical Battery" Company, Limited.—On Monday the hearing was resumed at the Marlborough-street Police Court of the charges of conspiracy to defraud brought against Messrs. C. B. Harness, J. M. McCully, and C. B. Hollier, in connection with the "Medical Battery" Company. The case was again adjourned.

The Board of Trade and High Pressure.—The President of the Board of Trade (Mr. A. J. Mundella) having had his attention called by Mr. Weir, M.P., to a recently published letter from Mr. James Keith, C.E., on the dangers of high-voltage electricity, has replied that the matter is receiving the Board's consideration.

Engineers and Shipbuilders.—A special general meeting of the North-East Coast Institution of Engineers and Shipbuilders will be held on Tuesday in the Physical Lecture Hall of the Durham College of Science, Newcastle-upon-Tyne. The discussion of Mr. J. R. Fothergill's paper, "On Mercantile Marine Engineers," will be resumed.

The Financing of Electrical Enterprises.—A telegram from Berlin states that Dr. Rosenthal, of Messrs. Siemens and Halske, and Mr. von Koenen are about to establish a banking business in Berlin. This establishment, in which Messrs. Siemens and Halske will be sleeping partners, will mainly direct its operations towards the financing of the electrical undertakings of the latter firm.

The Newport Tenders.—The Parliamentary and Improvement Committee of the Newport Corporation on Tuesday again considered the question of lighting the town by electricity. After a protracted discussion nothing definite was arrived at, but the members of the committee agreed to accept an offer made by Messrs. Crompton to inspect their work at Chelmsford before deciding upon a tender, and also to inspect a London central station.

The Potential of the Atmosphere.—M. André, the French professor who was injured some time ago in a balloon accident while taking atmospheric observations, has published a report of what he was trying to do. The experiments to determine the difference of electrical potential at different altitudes resulted in showing that in fine weather, when the electrical conditions are undisturbed, the strength of the electrical field remains unaltered however far it is tested along a vertical line.

The Gas Explosions in the City.—A report from Mr. W. H. Preece on the subject of the recent explosions on Ludgate-hill in two manholes was read before the City Commission of Sewers on Tuesday. Mr. Preece stated that the explosions were due to a collection of coal-gas and air in the boxes, but that the cause of ignition was not apparent. Since the occurrence the electric lighting company have introduced a system of inspection of such manholes so as to prevent a collection of gas in the manholes from leaky gas-mains.

Traction in New Zealand.—Dealing with the subject of electricity as a motive power on tramways, a Hobart paper concludes a leading article to objections raised by the

Digitized by Google

New Zealand Government as follows: "It may be hoped that the working of the Hobart system, which proves that all the dreaded difficulties of running the telephones and tram service side by side have vanished—mere chimeras evolved from nervous imaginings—will convince the chief of the New Zealand Telegraph Department that he can very safely leave the Dunedin Tramway Company to their own devices."

Society of Arts.—The second Cantor lecture by Prof. F. Clowes, D.Sc., on "The Detection and Measurement of Inflammable Gas and Vapour in the Air," will be delivered on Monday. It will deal with attempts to utilise diffusion and other physical processes, Liveing's electrical indicator, apparatus depending upon the alteration of volume caused by burning the gas, and apparatus depending on the measurement of volume of gas required to bring the mixture to the ignition point. On Tuesday, at 8 p.m., in the Applied Art Section, a paper on "The Adam Architecture in London," by Mr. Percy Fitzgerald, M.A., will be read.

The Dynamo-Electric Machine. — On Tuesday, before the Manchester Literary and Philosophical Society, Mr. Henry Wilde, F.R.S., gave a brief history of the dynamo-electric machine, and an account of his discoveries. He also gave experimental illustrations by means of the installation which he has presented to the society of the uses to which the supply may be put in philosophical research. Special interest was manifested by Mr. Wilde's exhibition of the new line which he has observed in the spectrum of thallium, and in experiments with his magnetarium to illustrate his theory of terrestrial magnetism.

Netherland Society for the Promotion of Industry.—As mentioned in a previous issue, this society desires to receive papers containing an indication of the means to obtain energy through windmills, to accumulate this energy electrically, to transmit it or to make it transportable, and more particularly an answer to certain questions given in a former issue is required. The prize offered is the gold medal of the society and a reward of £30. Answers must be sent before July 1, with the author's name in a closed envelope, to the general secretary of the society, Mr. F. W. van Eeden, at Haarlem, Holland.

Gas and Electric Light.—A meeting of inhabitants of Notting Hill and North Kensington has passed a resolution expressing the opinion that a parliamentary committee should be appointed to enquire into the present condition of the gas supply of London, with a view to legislation in the direction of securing a reduced and uniform rate of charge, the free use of meters, and a further diminution in the statutory rate of dividend. Mr. Rowlands, M.P., mentioned at the meeting that he was in favour of the municipalisation of the supply, but they had to see how far the electric light was going before they talked about purchasing the goodwill of the companies.

Underground Electric Railways in Paris.—It is reported that the French Chamber of Deputies will shortly be called upon to discuss the question of constructing a series of underground electric railways. A concession was granted by the Municipal Council over a year ago, but so far the consent of Parliament has not been given. The proposed line will run from the Porte Dauphine of the Bois de Boulogne, and thence under the Avenue Victor Hugo to the Arc de Triomphe, along the Champs Elysées to the Place de la Concorde, Rue de Rivoli, Place de la Bastille, Boulevarde Diderot, and then on to Vincennes—altogether nearly 10 miles, with 17 stations *en route*.

Electric Lighting of St. Paul's.—If the experiment about to be tried in St. Paul's Cathedral on a large scale is satisfactory, it is said that plant for generating the current will be put down in the crypt; but for the present the current will be drawn from the mains of the City of London Company. It is proposed to place 14 arc lamps in the dome, eight of them in the Whispering Gallery, and four in the quarter galleries, but the problem is how to find positions which shall not make the globes conspicuous in daylight. On a lower level, incandescent lamps will be arranged, and to the columns clusters will be attached on the east side, so that they will be invisible to worshippers who sit facing the communion table. The details have still to be settled.

The Waterloo and City Railway.—When the Waterloo and City Railway is in a position to begin tunnelling from the Royal Exchange to Waterloo, it will according to the *Financial News*, appeal for capital under favourable conditions; for at the forthcoming meeting of the London and South-Western Railway the shareholders are to be asked to pass resolutions sanctioning arrangements to guarantee the Waterloo and City capital, and to operate the electric line when completed. This is not to be wondered at; for the Waterloo and City Railway, remarks the same paper, is designed wholly as a feeder to the South-Western, and will, no doubt, get all the volume of traffic which passes over the South-Eastern from Cannon-street to Waterloo Junction daily, besides further popularising the south-western suburbs among City men.

Charges for Current in Leeds.—The Yorkshire House-to-House Electricity Company, of Leeds, state that the increasing demand for electrical energy has resulted in an extension of the works being decided upon, and at the same time a reduction in price will be made, commencing in April, when the charge per Board of Trade unit will be as follows: When the consumption for the quarter does not exceed 1,000 units, 7d.; exceeding 1,000 and not exceeding 1,500 units, 6¾d.; exceeding 1,500 and not exceeding 2,000 units, 6½d.; exceeding 2,000 and not exceeding 2,500 units, 6¼d.; exceeding 2,500 units, 6d. These prices will be subject to discount based upon the number of hours per quarter during which the current is used, each customer being called upon to declare the maximum number of lights required to be in use at any one time.

Arc Lamp for Lantern Exhibition.—The Leeds Photographic Society introduced a novelty at their annual lantern exhibition in the form of an improved lamp for projecting the slides on to a 22ft. screen. In past years various types of burners have been used—the blow-through jet, mixing jet, calcium, and saturator—all of which are good in their way, but this year the greatest improvement attempted was carried out, and electricity has taken the first place, and showed its infinite superiority to all forms of limelight. No gas-cylinder bursting was to be feared, and no hissing or cracked condensers took place to interfere with the exhibition, but a clear, steady, white light which showed up the slides to their best advantage. The lamp is the design of Mr. Borland, of Leeds, is self-regulating, and of constant focus, fitting on to the ordinary tray in any lantern, and occupies about the same space as a blow-through or mixing jet.

The Northern Society of Electrical Engineers.—The inaugural dinner of this society took place in Manchester on Monday. In the unavoidable absence of the president, Dr. John Hopkinson, F.R.S., Mr. Henry Edmunds, one of the vice-presidents, occupied the chair. He was supported by Messrs. G. E. Preece and W. P. J. Fawcus, vice-presidents, and the following members of the council: Dr. Edward Hopkinson, Messrs. J. Vincent Swindells, A. Eckstein, G. W. Lowcock, E. A. Claremont, Alex. Marr, J. H. Rider, J. Taylor, C. S. Northcote, Mr. Geo. J. Somerville, hon. treasurer, Mr. John Darney, hon.

Digitized by Google

secretary, and upwards of 50 members. After the toast of "Queen and Royal Family," Mr. G. E. Preece proposed "The Society" in a speech recapitulating its rise and progress from its inception. Other toasts were proposed and responded to by Messrs. E. Manville, W. P. J. Fawcus, S. Z. de Ferranti, and Dr. Edward Hopkinson. A musical programme which followed was much appreciated.

The Municipalisation of Tramways.—On Monday Justices Mathew and Collins gave judgment in the case of the London Tramway Company *v.* the London County Council. The Council had given notice under the Tramway Act to acquire a section of the company's system in Kentish Town, and Sir F. Bramwell was appointed by the Board of Trade as referee to determine the compensation due to the company. He awarded £64,500, but refused evidence of the annual rental on the ground that it would involve an allowance for past and future profit which the Act excluded. He based his award on the cost of the construction, less depreciation, whereas the company claimed 20 years' purchase of the annual value. Justice Mathew said he concluded that Parliament never intended such consequences to the company as were insisted on by the Council, and the award must be remitted to an arbitrator to deal with the question of valuation. Justice Collins concurred, and the award was accordingly sent back to Sir F. Bramwell for alteration of the amount. The County Council have decided to appeal against this verdict.

Electric Transmission of Power in Sweden.—An important installation of this nature was recently opened at Gringesberg, Sweden. The waterfall which supplies the power, says *Engineering*, is situated at a distance of some seven or eight miles from the mines. The Hallsjö waterfall has a height of 150ft., and the water is conveyed through a pipe of some 1,700ft. in length to the turbine-house, where there are four turbines of 100 h.p. each, and a smaller turbine of 20 h.p. Each turbine works a dynamo; the current is transformed from 100 volts to 5,000 volts, and conveyed to the Gringesberg and Björneberg mines through copper wires, 3mm. to 4mm. thick, attached to high poles. At the place of consumption the current is again reduced to 100 volts. At Björneberg there are installed an electric motor of 30 h.p. and 20 incandescent lamps, and at Gringesberg four motors of an aggregate of 110 h.p., 20 arc lamps, and 200 incandescent lamps. The power was previously supplied by several steam-engines and smaller local turbines, all of which sources have now been entirely dispensed with.

Lighting in Liverpool.—Before the Liverpool Engineering Society last week Mr. A. B. Holmes read a paper on the "Supply of Electrical Energy: Its Cost and Price." In the course of his remarks the author recorded the progress made since the year 1890 by the Liverpool Electric Supply Company. Since that date the length of street mains had been increased from 20 to 30 miles, and the number of lamps supplied from 12,000 to 25,000. The items which form the cost of production were dealt with seriatim, and attention was drawn to directions in which with an increased output economies in working may be attained. The load on a station supplying electricity for lighting purposes was shown to be extremely variable, the maximum load in winter being many times greater than the minimum load in summer, the cost of working the plant being much greater in consequence than would be the case were it possible to run the plant under uniform load. It was pointed out that great advantage would be derived from any practicable method of storage, but that the high cost of accumulators at present prevents their commercial use for that purpose.

A Sensation in Incandescent Lamps.—"The Star Electric Lamp Company," says a correspondent of the *Electrical World*, "has now on public exhibition on Michigan-avenue, Chicago, Ill., three incandescent lamps that are creating quite a sensation in electrical circles. In appearance they are ordinary 16-c.p. lamps, but it is claimed that by actual measurement one of them gave 720 effective candle-power, another 184, and the other 160. The light is perfectly white and steady, while the filament seems scarcely larger than in the ordinary lamp. The lamps were connected directly to the Edison mains, and the instruments showed that the lamps were burned at 111 volts. The amperes averaged, it is claimed by those present, one eighth ampere per lamp. Inventor John Kammer stated that these unusual results were obtained by introducing into the bulb a peculiar vapour which he recently discovered. The difference in illuminating power is determined by the quantity of vapour in the bulb. Mr. Kammer's efforts are now being directed to perfecting a one-watt lamp, and from the results already secured with his vapour treatment he expects to place such a lamp on the market in a very short time."

Cause of Electric Currents Observed in Plants. Mr. O. Haacke, in the *Ann. Agron*, deals with this subject. He states that, according to Künckel, electric currents in plants are due to the movements of water in the tissues, and not to differences of potential, existing independently. The author considered it probable that vegetable electricity was due to biological processes, especially respiration and the consequent chemical changes. He experimented with leaves and flowers of dicotyledons and on a large mushroom in an atmosphere of hydrogen. The electric current was diminished, but never quite suppressed, owing, probably, to intramolecular respiration. On readmitting air, the electric current revives. Young bean plants behaved differently, the current being increased in an atmosphere of hydrogen. This is explained by the known fact that beans are distinguished by a very high intramolecular respiration. Flowers, and especially stamens and pistils, show very decided oscillations under the influence of electric currents. It is not possible to state exactly in what manner respiration gives rise to electric currents without a knowledge of successive chemical changes which take place during respiration. The results of the author's experiments seem to indicate that vegetable electricity is not exclusively due to filtration of water.

Electrolytic Estimations and Separations.—In a paper in the *Monatsh*, Mr. G. Vortmann describes the behaviour on electrolysis of salts of zinc, iron, cobalt, and nickel, to which solutions of an alkaline tartrate and an alkaline hydroxide have been previously added. Of these metals, the three first named may be quantitatively deposited from the alkaline solution; whilst, under the same conditions, the last named remains in solution, thus affording a method for the separation of nickel from zinc, iron, and cobalt. Iron may be separated from zinc in alkaline tartrate solution by employing a cathode of platinum, whereby the iron is deposited with only a trace of zinc. By dissolving and redepositing two or three times, the iron is obtained entirely free from zinc. To estimate zinc in presence of iron, potassium cyanide is first added to the solution, whereby the iron is converted into potassium ferrocyanide; sodium hydroxide is then added and the current passed, when the zinc is deposited, the iron remaining in solution. The author further describes a method of estimating cobalt, nickel, and copper when present with much iron. A solution of the metal, in which the iron is present as a ferric salt, is placed in a platinum dish and treated with excess of ammonia,

Digitized by Google

and the current passed, whereupon, without the necessity of filtering off the ferric hydroxide, cobalt, nickel, and copper are thrown down on the cathode in a well-adhering mass. In the separation of copper and iron, the latter metal is best oxidised with nitric acid.

Lighting of the City.—Mr. Bridgman, the retiring chairman of the Commission of Sewers, gave on Tuesday a review of the past year's work. Referring to the electric light, he stated that there were now 479 electric arc lamps in use, costing £26 each, or £12,454 per annum. Experiments had been made in Aldermanbury and Basinghall-street with incandescent lamps, with a view to determine the most desirable method of lighting from the centre of the streets, and had also been made in Lower Thames-street. In testimony of the satisfactory progress of electricity in the City, nothing could be more eloquent than the recent decision of the Commissioners to remove the old gas lamps at an early date from the main thoroughfares, which had been maintained, at an annual cost of about £1,182, ready for lighting in case of failures in electrical illumination. The question of appointing electric light inspectors was now under consideration. Negotiations were in progress with the City of London Electric Lighting Company respecting the use for telephonic purposes of certain of the tubes laid by them, the Commissioners refusing their consent to the tubes being appropriated to any other purpose than for electric lighting without some substantial concession to the ratepayers. With this in view, the Commissioners sought to impose the obligation that the future price of telephones should not exceed £8 per annum. This proposal, however, did not find favour with the City of London Electric Lighting Company, and the matter still remained in the negotiation stage.

The Hobart Electric Tramway.—Some time ago we referred to this tramway, which is worked by an English concern, the Hobart Electrical Tramway Company. The line is single, and is about 10 miles long. The steepest gradient is on the Newtown line, where for about 350 yards there is a 6 per cent. rise. In other places there are some rather severe curves and gradients. The rails are 40lb. Vignoles rails, with guard-rails throughout, the joints being spanned by copper strip riveted to the rails. The trolley wire is supported from poles on either side of the street, galvanised-steel wires being used for suspension. The power-house and carshed are situated near the Hobart river, being built on cement concrete set on piles. The power-house consists of a galvanised-iron shell with wrought-iron girders and columns, with brick and wooden partition walls. There are four Marshall multitubular locomotive boilers, giving steam at 160lb. pressure to three Willans central-valve high-speed compound engines running at 350 revolutions. Two Worthington steam-pumps pump the feed-water through two Marshall feed-water heaters of 100 h.p. each. There are three compound-wound Siemens dynamos, giving 250 amperes each at 500 volts, coupled directly to the engines, on one bed-plate. The shaft of each carries a fly-wheel 4ft. 2in. in diameter. Two Siemens 15-h.p. motors are used for each car, geared to the car axles with single-reduction spur gearing working in oil. The tramway is equipped with a steam and electrical plant, furnished by Messrs. Siemens Bros., of London. The rolling-stock was also furnished by the same company, although the contract was sublet to the Lancaster Wagon Company.

Electrical Trades Section.—A meeting of the Electrical Trades Section of the London Chamber of Commerce was summoned for Monday last, the 22nd inst., at 3.30 p.m., to consider, amongst other matters, the following important questions in their connection with the electrical industry: (1) The advisability of the industry as a whole lending its support to the Antwerp Exhibition, which opens in May next and closes in the following November; (2) a report of the action of the Traction Committee; and (3) the appointment of a Parliamentary Committee. Owing partly, however, to the somewhat short notice that had been given to the members, there was an extremely small attendance, so that, after reading and confirming the minutes of the last general meeting, it was decided—Major Flood Page being in the chair—to adjourn the meeting for a week, when it is hoped and expected there will be a large number of members present to discuss and decide upon the matters brought forward. One reason why the meeting was called for Monday last was that the feeling of the industry might to some extent be gauged with regard to the Antwerp Exhibition, as the English commissioners had arranged to meet yesterday at the Mansion House, and were desirous of being guided as far as possible by the expressed opinions of trades and industries. The Traction Committee, it is understood, have not yet been able to prepare a final report, being still discussing details and definitions with the Board of Trade; but such progress as has been made will be reported to the members at the meeting. We understand that they have been received very favourably by the Board of Trade in their efforts to secure full scope for the free development of electric traction, and it is likely that an actual joint meeting of the committee and Board of Trade officials will take place shortly with a view to discussing doubtful points. The meeting on Monday next, the 29th inst., is to commence at 3 p.m.

Testimonial to Mr. H. Newman Lawrence.—A movement is on foot to present a testimonial to Mr. H. Newman Lawrence, and a circular is now being issued with this object in view by a committee of well-known electrical engineers. We abstract the following from the circular: "The attention of members of the medical and electrical professions is directed to the case of Mr. H. Newman Lawrence, an earnest worker in the field of electro-therapeutics, who finds himself in embarrassed circumstances, brought about, in no small measure, by the disrepute into which electro-medical treatment has gradually fallen in the estimation of the public, through the practices of those with whom Mr. Lawrence has been in no way connected. Throughout he has also been unremitting in his denunciation of quackery in the columns of the *Electrical Review* and other scientific journals, as well as in numerous public lectures. It is a curious instance of the irony of fate that Mr. Lawrence should have been conducive in turning the tide of public opinion to such an extent as to bring about so strong a reaction from blind credulity to utter disbelief in the curative properties of electricity, that the committee understand there is little or no electro-therapeutic work of any kind now being carried on outside the hospitals. The above circumstances, which have come to the knowledge of the members of the committee, seem to them to constitute a case in which they can confidently appeal to their professional brethren—both electrical and medical. They consider that a suitable testimonial would not only be of great service to the recipient, but that it would be both well deserved and worthily bestowed. They have ascertained that Mr. Lawrence has an opportunity of making his way in the United States, and they propose that the funds that may be raised as a result of this appeal should be devoted to furthering this object. Subscriptions will be received by the joint secretaries (Mr. Ed. C. de Segundo, 28, Victoria-street, Westminster, S.W., and Mr. Thomas Adams, 24, Hillfield-road, West Hampstead, N.W.), or they

Digitized by Google

may be paid into the 'Lawrence Testimonial' account at Lloyd's Bank, Limited, 54, St. James's-street, London, S.W."

Underground Conduits in the United States.—Of the large number of underground electric wire conduits which have been used or proposed, there are at present in successful use in America, on a large scale, four typical forms: iron pipe, which may be either cast or wrought; cement-lined sheet-iron pipes; tile, terra-cotta or clay pipes; and wood tubes. The most generally used, according to Prof. Jackson in *Cassier's Magazine* for January, are the earthenware conduits, and the most used of them are made of glazed terra-cotta, in sections 3ft. long, with one or more rectangular ducts, each capable of carrying at least three cables. In Milwaukee an ordinary cement sewer pipe has been laid in the same manner as the tile, with cemented joints, and it makes a very fair conduit, which is a little cheaper than the special forms. The pipes are softer than vitrified tile, and therefore more liable to mechanical injury, but the system has not yet been long enough in use to fully decide on its comparative merits. The simplest of all conduits, and one which is used quite generally, is a common wrought-iron gas or steam pipe, either laid bare in the ground or in a bed of concrete. Ducts are usually of 2in. or 3in. pipes, and since a 3in. pipe will carry four ordinary electric light cables, the system is economical of space in the streets. One cable can be pulled out when the others are in the ducts, but the practice of handling cables separately when several are in one duct is not advocated by the most experienced. Joints in the pipe are made with a sleeve screwed on with a vanishing thread, which is cut so that the ends of the pipe comes close together inside the sleeve. The sections of pipe are generally 20ft. long. The great advantage iron pipe has over all other forms of conduit is its flexibility. It may be bent in any direction at any point, to avoid obstacles in the streets, and it should always be used when obstacles are particularly numerous. Some authorities claim that a conduit should never bend, but experience in New York and Chicago proves that cables can be pulled easily around several bends with radii of 3ft. or less. Tubes of wood, treated with various substances to preserve them, have been manufactured by several companies, and quite generally used. At present Philadelphia probably has in use a greater length of wooden conduit than any other city, though there is considerable of it in Chicago and Brooklyn. The commonest form of wood conduit is made up of 4in. by 4in. pieces of wood with a 3in. hole bored through from end to end. These are joined either by a male and female union, or by simply butting the ends together. A cement-lined iron pipe conduit consists of a tough sheet-iron shell, riveted and lined with ⅛in. of pure cement, no sand being used, and the inside being carefully smoothed. The pipes are made in 8ft. lengths and of various diameters. All of these conduit systems are in successful operation on a large scale, but the period of use, the professor concludes, has not yet been long enough to prove positively that they will all endure satisfactorily. The users of each appear to be well satisfied.

Gas Leakage and Electric Light Mains.—Yesterday's issue of the *St. James's Gazette* contained an article on "Electricity as a Street Danger," in connection with the recent explosions of gas in electric light manholes. A representative of that paper has interviewed three electrical engineers on the subject, and the substance of their remarks is given in the article in question. We extract the following: "In every little accident of this kind that I have known," said the engineer in charge at the Westminster Electric Supply Corporation's fine works, "the cause has been the gas leakage and accumulation in either the culverts or the boxes. In the case of the St. Pancras people it would probably be in the culvert; but it all depends what system the cable is laid on. They had three or four cases of this kind at Glasgow recently that caused a little trouble. It is also possible that an explosion of the kind might be due to water getting into the culvert. The current decomposes the water into its constituent gases and the gas is exploded. But I have never heard of but once case where that has happened." Major Flood Page, the deputy-chairman of the Edison and Swan United Company, said: "Did you ever know of earth being turned up in London that didn't smell of gas—even when they were not doing anything to the gas-pipes? Gas has been escaping into the ground for many years, until the earth everywhere around us is permeated with it. Then comes a spark of electricity and sets fire to it." Asked as to why that should happen, he replied: "Well, of course, there may be an excessive current carried along, and some little corrosion of the insulating material may cause a spark. These explosions are not the fault of the electricity; we simply realise now what we have all along known, that these gas-pipes have been permitting gas to saturate the ground. It reminds me that somewhere about 1803 or 1805, when gas was first used in London, the King got into a great fright lest the streets should be blown up; and a number of the leading scientific men of that day solemnly assured him that there was no foundation for the fear that the horses going along in them would be sent flying into the air. We have found they were quite right—that people and horses have not been sent flying up into the air—but all the same, the gas-pipes have leaked, the ground has become saturated with gas, and now the presence of the electric cables has introduced an element of danger. But it is not at all a serious matter. This kind of thing will happen very occasionally, and so far we have no misfortune to lament. I don't think there need be the slightest alarm." The Major further stated that he did not anticipate that there will be any serious number of accidents. Continuing, he remarked on the question of low tension *versus* high tension: "The low tension means that they work at about 100 volts pressure, and the high tension that they work at about 5,000 volts, but transform it down before it gets into the consumers' houses. Inside the houses the one kind is as safe as the other. Outside the houses—well, no accident can happen from a man laying hold of a low-tension system, but a man might be killed by laying hold of a high-tension. When the Americans tried to kill criminals by electricity they were at first laughed at because it took so long to do it. They applied electricity to the head and the hair, which is the worst conductor we have in our body; whereas a man who grasps a wire with his hands instantly forms a circuit and brings the whole current through his body, and a high-tension current would kill him. But, high or low, there is not the slightest danger of any gas-main exploding or being in any way affected by the currents passing along the electric mains. If you come to think," pursued the Major in a burst of eloquence, "of the enormous use of electricity now, and the millions of incandescent lamps and thousands of arc lamps that are being used all over Europe, and with an infinitesimal percentage of accidents—not anything like the number from gas; and when you remember that the use of gas, lamps, and candles causes something over 500 fires in the London district every year, while the number caused by electricity doesn't reach more than three or four, you will see that there can be no question—it is absolutely beyond dispute—that electric lighting, carried out as it is here with care and proper caution, is by far the safest artificial illuminant the world has ever known."

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

(All rights reserved.)

(Continued from page 9.)

INSULATION.

The object of insulating matter put on copper conductors is to confine the current as much as possible to the copper, and to allow as little as possible to flow through other paths and so leak away. The leakage of water in a pipe is somewhat analogous to the leakage of the electric current flowing along a conductor: the longer the pipe and the more joints there are in it, the greater will be the chance of leakage; and it is similar with electricity. The two typical substances for conducting and insulating purposes as used in practice are copper and indiarubber. The conductor is made of copper, because it is desirable to have the resistance to the current as low as possible; the insulation is made of indiarubber, because it is desirable to obstruct the current as much as possible. The copper conductor is made of such a sectional area that a certain current can flow without unduly heating the metal; and since the specific resistance of indiarubber is enormously higher than that of copper, it follows that only a most minute current can leak through the insulation. The conditions under which electricity is supplied reduce considerably the great difference between the two, and instead of the ratio of the specific resistances of indiarubber and copper being billions to one, it is brought down to thousands to one, which is a ratio we are more capable of conceiving.

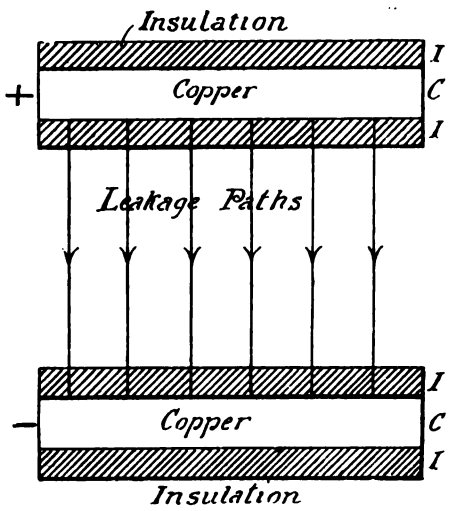

FIG. 40.

We will consider the case of a couple of conductors, say, 200 yards long, and take the ratio of the specific resistances of insulation and copper as $6 \times 10^{16} : 1$. Let the depth of the insulation be, say, ·5cm., and the diameter of the copper 1cm., as shown in Fig. 40; then considering the insulating matter first, the length of its path is extremely short, while the cross-sectional area is enormous. The reason of this is because the current does not tend to flow along the cylindrical tube of insulation, but tries to flow *through* the insulation covering *in the direction of its depth*, and thus through the air space or whatever intervenes between the two conductors, then through the depth of the insulation of the second conductor, and so complete its circuit. This leakage does not happen at one point or many, but at every point along the conductors, and at every point around the circumference. This being so, the sectional area of the insulation is measured by the cylindrical surface exposed by the whole of the conductors, and this surface is obtained by multiplying the length of the conductor by the mean circumference.

The total length of the insulating path is extremely short, being evidently the depth of the insulating matter that covers the copper conductors, and as there are two conductors so this total length is measured by twice the depth of the insulation. The intervening space between the copper conductors cannot always be calculated as part of the insulating path, because the insulation on each conductor is in contact with earth at some points. And even when the conductors are suspended in air, or embedded in bitumen-filled pipes, there is bound to be some supporting points where contact of the insulation with earth occurs.

The following gives a general law showing the ratio between the two:

Let l signify length of cable;
„ D „ outer diameter of insulation;
„ d „ inner „ „ „

Then $\frac{1}{2}(D-d)$ signifies thickness of insulation, and d signifies diameter of conductor.

The sectional area of the conductor $= \pi d^2 \div 4$;

„ „ „ „ insulation $= \left(\frac{D+d}{2}\right)\pi l$;

the length of the conductor $= 2l$;

„ „ „ insulation $= (D-d)$.

It is assumed, to simplify matters, that the two cables are buried, say, a foot apart in the ground, which we will further assume is slightly moist, so that the outside surfaces of the insulating matter on each cable is being to earth in a most evident manner. The resistance of the path of the leakage current is measured simply by the thickness of the insulation on each cable, because the resistance offered by the "earth" is of a negligible quantity; the thickness of the insulation being $\frac{1}{2}(D+d)$, and there being two thicknesses to penetrate—one on the positive cable and one on the negative—the total path = twice the thickness, or $(D-d)$. The mean diameter of the tubular insulating covering is evidently $\frac{1}{2}(D+d)$; hence the mean circumference is obtained by $\frac{1}{2}(D+d)\pi$, and multiplying this by the length, l, gives the mean sectional area $= \frac{1}{2}(D+d)\pi l$. Inserting the respective values, we thus have:

$$\text{For conductor} \quad R_c = \frac{8l}{\pi d^2} + \rho.$$

$$\text{For insulation} \quad R_i = \frac{D-d}{l\pi\left(\frac{D+d}{2}\right)} + \rho_1,$$

where ρ and ρ_1 signify the specific resistances of the copper and insulation covering respectively.

It is impossible to say what the specific resistance of insulating covering might be. The maximum would be if the covering were made entirely, say, of indiarubber, but of course it never is—the number of layers of indiarubber put on varying with the quality and make of the cable. We will assume, therefore, that specific resistance of the covering, is, say, 6×10^{16}; that of indiarubber being about 6×10^{20}, copper being taken as unity.

Hence, the ratio of the specific resistances of the insulation and copper is $6 \times 10^{16} : 1$. Inserting the value of 6×10^{16}, we have the ratio between insulation and conductor:

$$6 \times 10^{16}\left\{\frac{D-d}{l\pi\left(\frac{D+d}{2}\right)}\right\} : \frac{8l}{\pi d^2};$$

or,
$$6 \times 10^{16}\left(\frac{D-d}{D+d}\right) : \frac{4l^2}{d^2};$$

or,
$$1{\cdot}5 \times 10^{16}\left\{\frac{d^2}{l^2}\,\frac{(D-d)}{(D+d)}\right\} : 1.$$

Fig. 40 gives a sectional view of a pair of insulated conductors showing the leakage paths across from copper of one conductor to the copper of the other. From this it can readily be understood how it is that when mains are laid along casing which becomes moistened or damp, the leakage is increased. Although the difference between the specific resistance of the insulation and that of the conductor is so enormous, yet it is reduced quickly. The length of the conducting path was assumed to be 400 yards, and the length of the insulating path is taken as twice the depth, or $2 \times {\cdot}5 = 1$cm., so that the latter path is only about $\frac{1}{400 \times 36 \times 2{\cdot}54} = \frac{1}{36{,}576}$ of the length of the former. The ratio at the start was taken as $6 \times 10^{16} : 1$, and

this now becomes reduced at once to more than 36,000 times, because the conducting path is about 36,000 times as great as the insulating path. Again, we must consider the ratio of the sectional areas of the two paths. The sectional area of the conducting path is $\frac{3{\cdot}1416 \times {\cdot}5^2}{4} = {\cdot}2$ square centimetre. The sectional area of the insulating path is the mean circumference of insulation × length of conductor = $1{\cdot}5 \times 3{\cdot}1416 \times 200 \times 36 \times 2{\cdot}54 = 86{,}180$ square centimetres. Thus the sectional area of the second is 430,000 times as great as that of the first, and consequently the resistance of the insulating path will be reduced 430,000 times, and the ratio is now further reduced, so that finally the insulating path may be taken as having a resistance about $1{\cdot}5 \times 10^9$ times as great as that of the conducting path, and hence a most minute part of the total current leaks away through the insulation, and is wasted. All these figures are very approximate to the case considered, and are given simply to give an idea of the relation that may exist between the insulating and the conducting paths. The amount of the leakage current is about the best test we can have respecting the state of the insulation on an electric light circuit.

It is of the utmost importance that every part of the circuit of an installation should be well insulated, otherwise there will be continual trouble—the current will leak, fuses get blown, and the short-circuits may overheat the wires and cause a fire to break out. The state of the atmosphere has a great deal to do with the condition of the insulation of the circuit. If the weather be fine and dry, very little leakage will be discovered on testing; but test the same circuit on a wet day, when the atmosphere is charged with moisture, and very different results are sometimes obtained. The damp air produces moisture on the surfaces, and so enables the current to creep or leak. This "surface leakage" is not confined to such material as wood, but also acts on such insulators as glass and porcelain, materials which in dry weather form excellent insulators. It must be remembered that England is a rainy country, and has more often a moist than a dry atmosphere—in fact, we rarely get a dry atmosphere such as is known in warmer climes, so insulation which will do for other countries will not do for us. In addition to the leakage itself, moisture tends to set up electro-chemical action, and the insulation and the copper thus get acted on chemically and destroyed. All circuits should be systematically and frequently tested, so that the slightest sign of any incipient fault becoming developed can be detected as soon as possible and the fault removed before it can do any harm. The insulation resistance of electric light cables is quoted as so many megohms per mile. This expression is technically wrong, because insulation resistance varies inversely as the length of the cable—that is, if one mile of cable has a resistance of 1,000 megohms, then half a mile will have an insulation resistance of 2,000 megohms, and two miles 500 megohms, etc.; hence the insulation resistance should be expressed as one factor of a product. Thus 1,000 megohm-miles, meaning one mile, will be 1,000 megohms, or 1,000 miles will be $\frac{1}{1000}$ of a megohm = 1,000 ohms.

High-insulation cables are made to give 1,000 megohm-miles, and are insulated with vulcanisod indiarubber, which material seems to find most favour for insulating purposes. A cable of this class would be suitable for high-pressure currents. For low-pressure currents the insulation resistance need not be so high, 300 megohm-miles being reckoned sufficient.

Insulated cables have now been brought to a high standard of perfection, particularly since high-pressure currents have been in general use, and where the conductor is required for damp places the exigencies of the case have been successfully coped with. Each manufacturer has his own ideas respecting the best method of building up the insulation covering, and we think we cannot do better than to append the valuable tabulation drawn up by Mr. W. H. Preece, as given in his paper, entitled "Specification of Insulated Conductors for Electric Lighting and other Purposes," read before the Institution of Electrical Engineers on December 10, 1891.

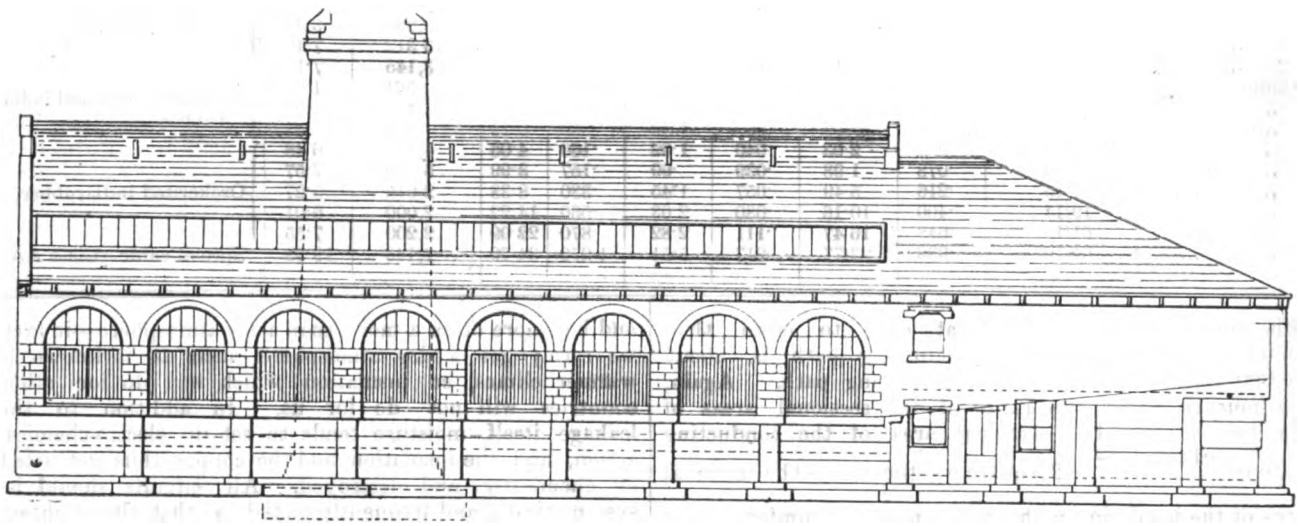
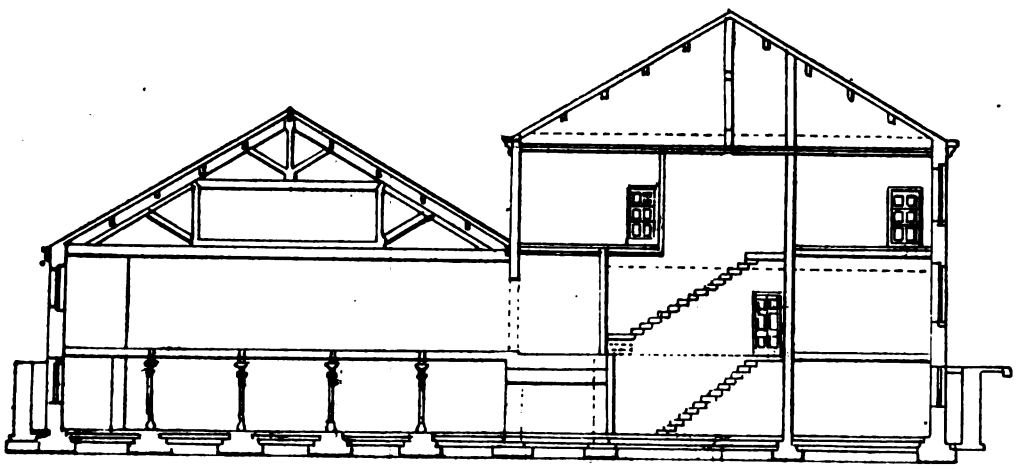
HUDDERSFIELD ELECTRICITY SUPPLY.

The following description of the Huddersfield municipal electricity supply station has a peculiar interest for engineers and members of a local authority, for it is an instance of a thoroughly successful undertaking conceived and carried into execution by the will of a far-seeing Corporation working through an energetic committee. Huddersfield has played the *rôle* of pioneer in many municipal undertakings, and when face to face with the electric lighting question, acted upon its usual courage of conviction at a time when many doubted the wisdom of municipalising electricity supply, and the utmost ignorance and prejudice prevailed against the use of high-tension generation of the electric current. Time has rapidly, since the Huddersfield Corporation threw their weight into the scale of both of the above causes, justified their foresight. The initiation of the undertaking was delegated to the Gas Committee, who visited a number of towns with a view to inspecting the various available systems. After very careful consideration of the

SOUTH ELEVATION



WEST ELEVATION



SECTION

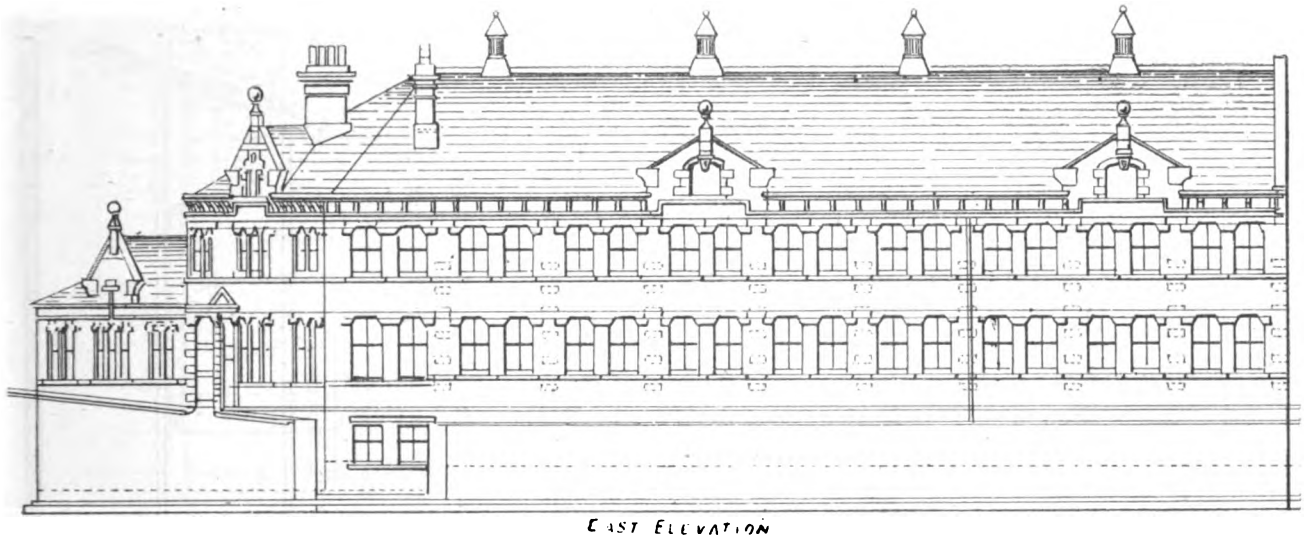
Huddersfield Electricity Supply Station.

Digitized by Google

respective advantages offered, they decided that the balance was in favour of distribution by low pressure with generation at high pressure by alternate currents. This at once enabled them to remove the works away from the centre of the town, and at the same time to extend their supply area until the whole of the somewhat scattered outlying districts are included. Having obtained tenders from those firms who were in a position to carry out the whole undertaking, they accepted that of the Brush Electrical Engineering Company.

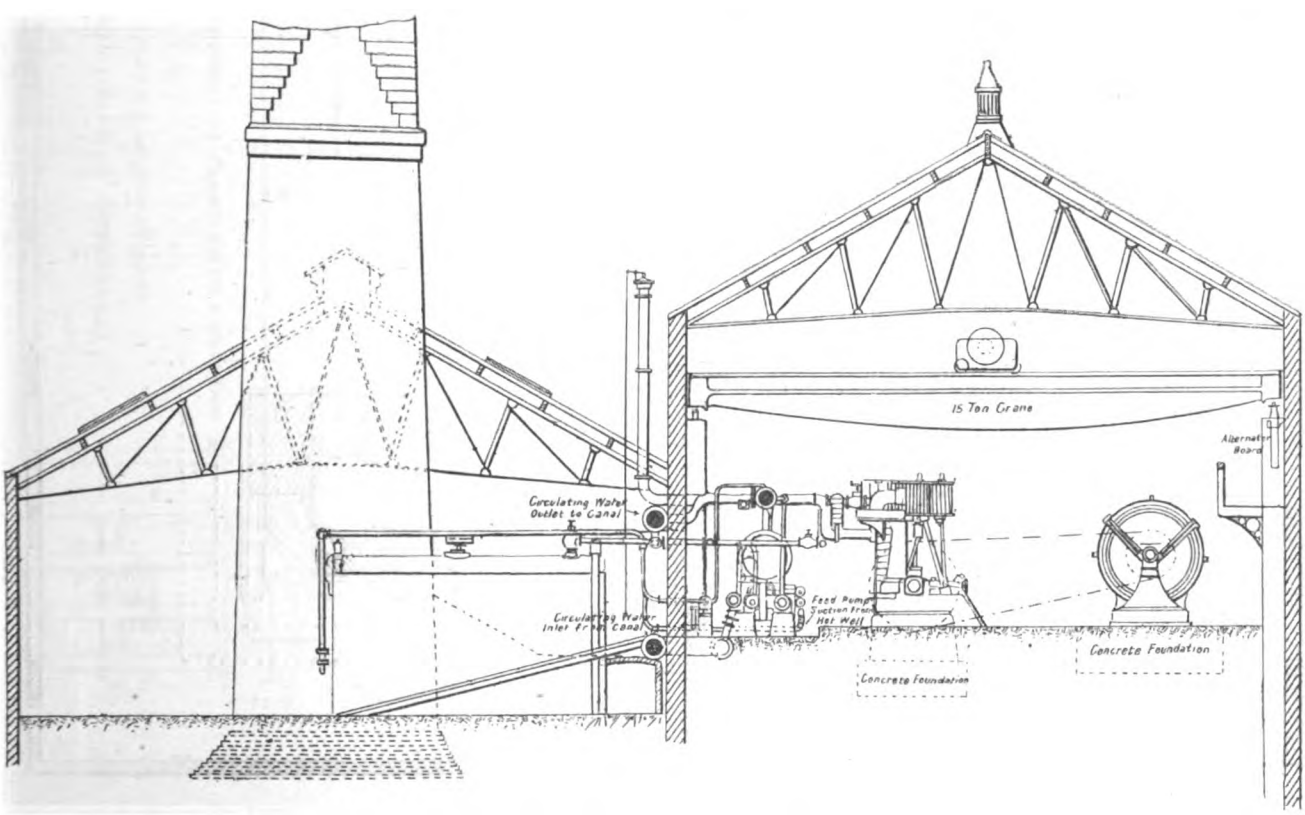
Application was duly made to the Local Government Board, whose sanction was obtained in May, 1892, when the buildings were promptly commenced. In July, however, an untimely strike in the masons' trade so delayed the work that all hope of completing in time for last winter was abandoned. The inauguration took place on July 29 last, since which date the Corporation have provided a continuous supply throughout the principal streets.

The generating station, of which we give several views, together with detailed plan and elevation, is situate on land adjoining the canal and the gasworks (which are also the property of the Corporation). The buildings, which are most substantial, have a frontage in St. Andrew's-road of 117ft., the engine-room being 105ft. long by 50ft. wide, the boiler-house being the same length and 54ft. wide. The chimney, which is 6ft. internal diameter and 200ft. high, is unusually handsome; we give a sectional view of it. It was designed by Mr. B. Stocks, the chairman of the Gas Committee, whose unsparing services have very largely contributed towards the successful introduction of the electric light into Huddersfield. The buildings have been specially designed with a view to facilitate the carrying out of future extensions, while at present plant for 40,000 lamps can be conveniently accommodated.



Huddersfield Electricity Supply Station.

Boilers.—Steam is supplied to the first instalment of plant from four Babcock-Wilcox boilers, each capable of supplying about 5,000lb. of steam per hour at 150lb. pressure. Each boiler has a heating surface of 1,411 square feet, and a grate area of 26½ square feet, and each has 63 tubes 4in. diameter and 18ft. long, with a steam drum 36in. diameter and 23ft. 7in. long. The brick setting of the boilers has been specially designed by the Brush Electrical Engineering Company's superintending engineer (Mr. Geipel) with a view to minimising loss by radiation from the brickwork,



Section—Boiler and Engine Room—Huddersfield.

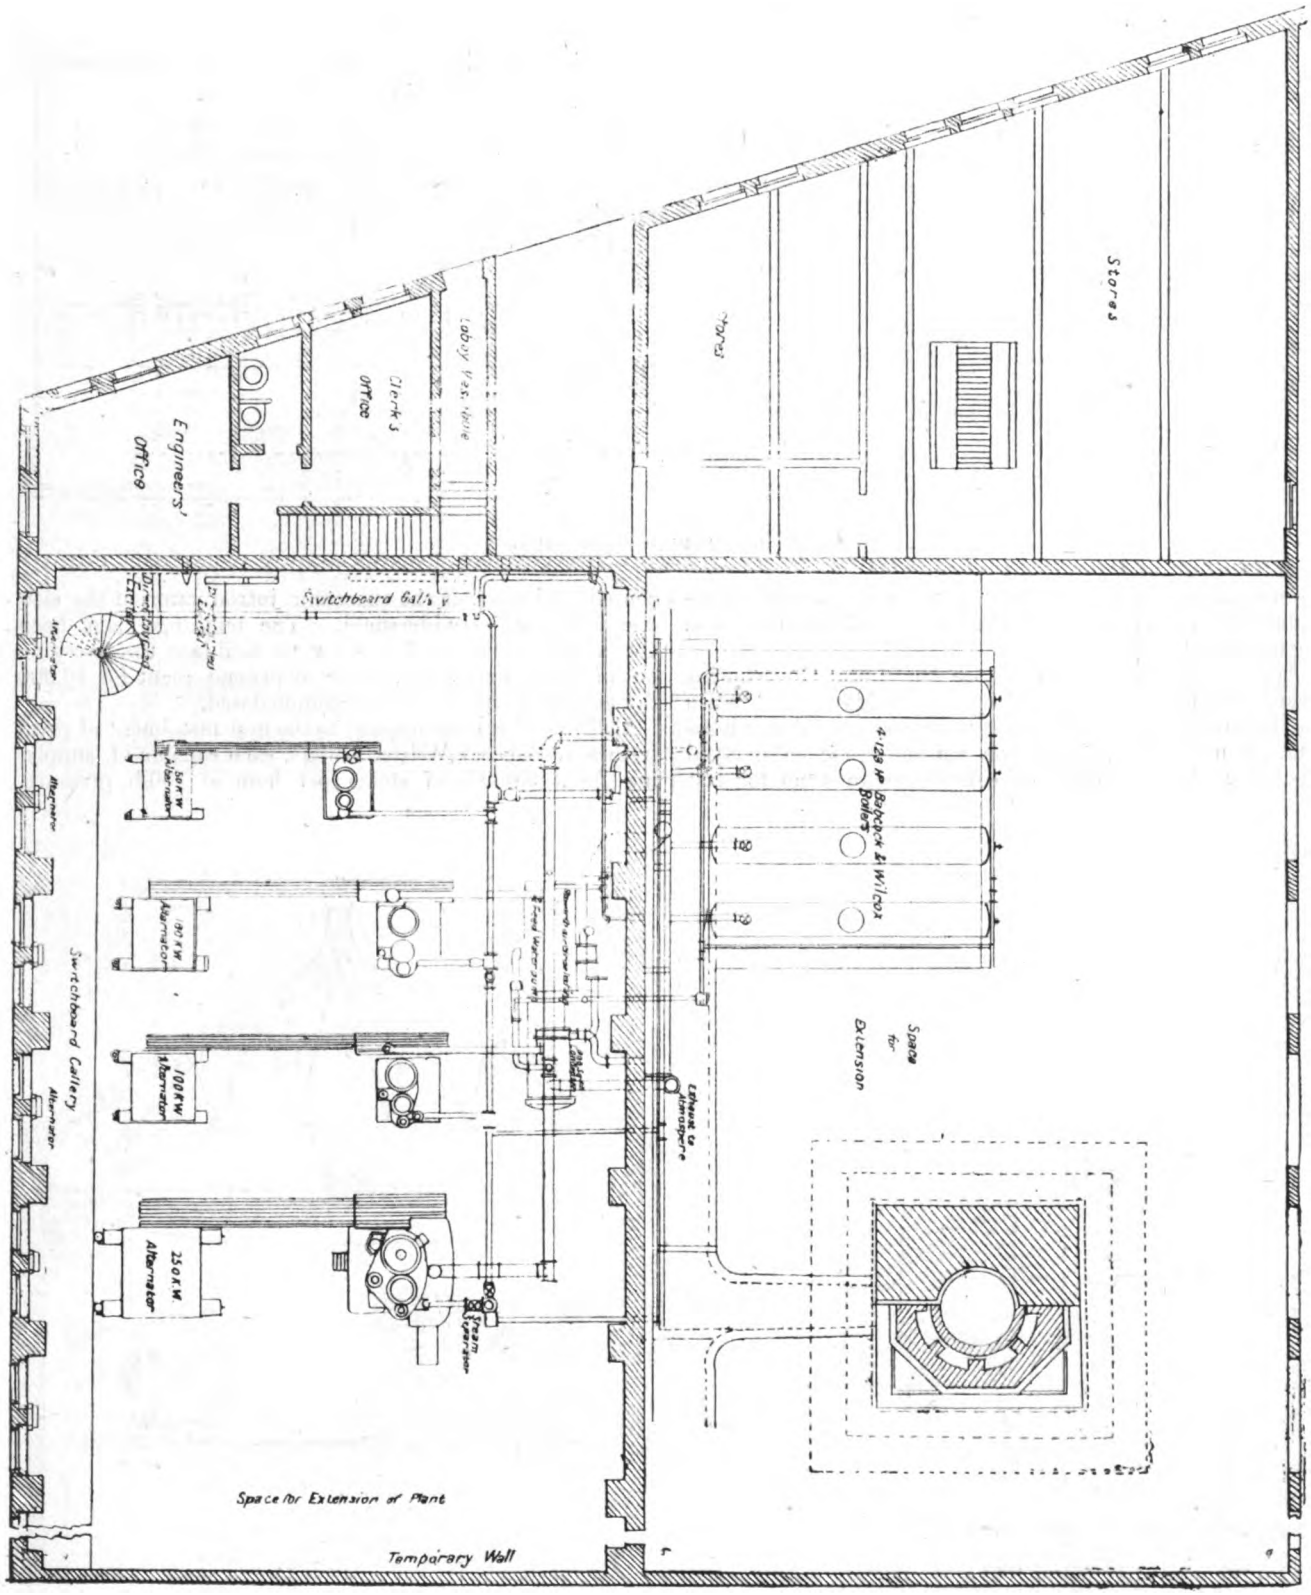
and although no careful tests have yet been made, some economy may be expected, as it has been ascertained that the heat of the outside walls is less than with the usual settings. An illustration of this setting is given in which it will be seen that an air-space divides the inside from the outside of the setting, thus reducing the transmission of heat to outside.

pipe to operate the exciter engines. The whole of the valves are of the parallel slide type, so that when open the steam has a straight passage through ; while in the larger valves it is arranged that the first turn of the handwheel opens a small by-pass valve, which at once serves to prevent too sudden an influx of steam, and relieves the pressure on the main valve, so that the latter may be opened



Plan of Station—Huddersfield.

Crane.—The engine and dynamo room is traversed by a 15-ton crane, operated either by hand or by a 9-h.p. Brush-Victoria motor, current being obtained from one of the exciters, the various movements being controlled by clutch gear.

Steam-pipe.—The main pipe is of wrought iron 6in. in diameter, and forms a ring with valves so arranged that any section may be isolated. The branches to the main engines are 4in. and 3in. Reducing-valves are inserted in each steam-

with ease. The exhaust piping, which is of cast iron, ranging from 10in. diameter downwards, opens into the condenser or direct to atmosphere, as may be desired. There is an automatic relief valve on the pipe which opens the exhaust to atmosphere in the event of stoppage of the condensing plant, while a large straight-through valve shuts off the condenser when required.

Condensing Plant.—This is so arranged that it may be readily extended along with the engines, for which

Digitized by Google

reason a 16in. pipe has been fixed for leading the cooling water from and to the canal. This pipe is capable of supplying water for about 10 times the cooling surface of the present plant, and is arranged so that it may be tapped as each additional condenser is fixed. At present there is only one surface condenser of 900 square feet cooling surface, into the top of which leads a branch from the

main exhaust with a valve for closing the inlet. The Raworth air and circulating pumps are horizontal, and are fixed on one bed-plate, and are driven by a pair of compound cylinders. This combination has been specially designed for central-station work, with a view to economise the consumption of steam. The whole of the pumps are worked by one pair of compound cylinders, while a heavy flywheel is provided to enable the steam to be cut off and used expansively. The diameter of the air-pump is 13in., the circulating-pump is 11in., the high-pressure cylinder 5in., and the low-pressure cylinder 8½in., and the stroke of each is 10in. A by-pass valve is fixed on the circulating-pump in order to control the cooling water to suit the quantity of steam to be condensed, and to regulate the temperature of the hot-well. A general idea of the pump may be obtained by reference to the plate.

Feeding Arrangements.—The principal feed pumps are driven by the same engine as the air and circulating pumps from a rocking shaft. The pump rods are attached to blocks which slide in slotted levers, by means of which the stroke may be varied as required. The feed-water is drawn from the hot-well under the air-pump, a replenishing cock being fitted to both the town supply and to the circulating or canal-water pipe, so that the feed may be made up from either source. In addition to this there is a Worthington

Digitized by Google

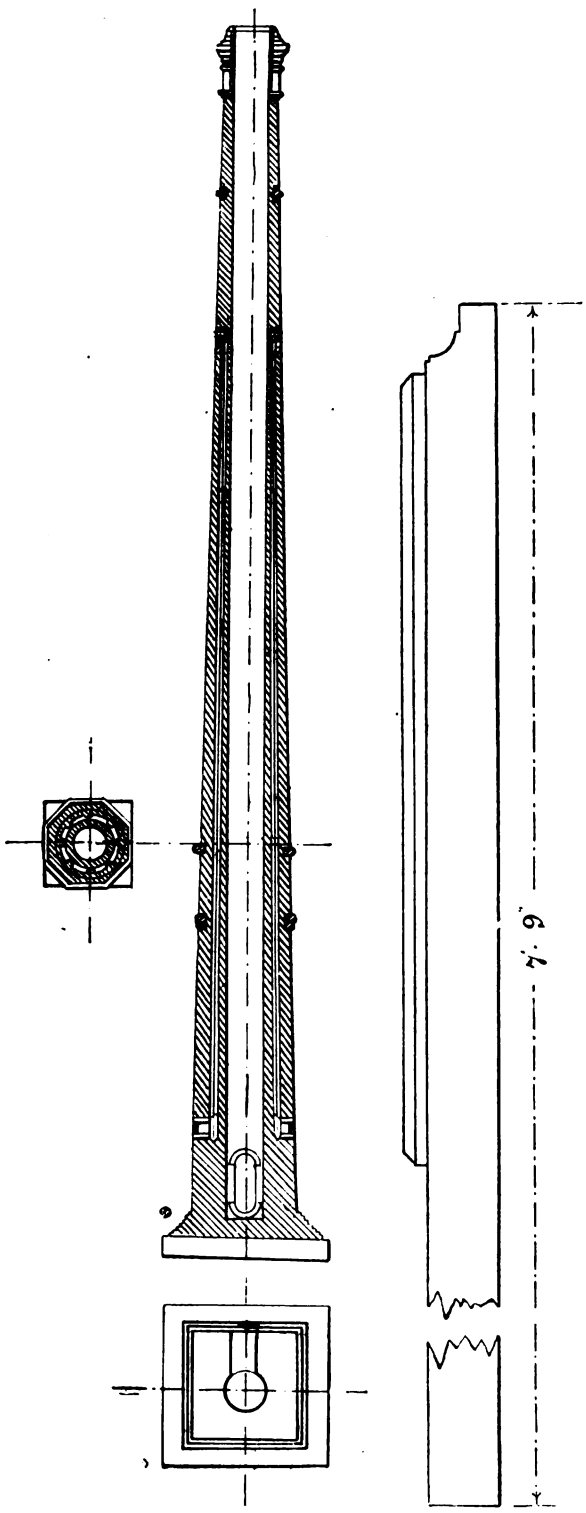
pump supplied as a stand-by—this pumps direct into the boilers from either town supply or canal pipe. The feed-pipe is also arranged on the ring-main principle, with suitable valves for isolating any section. The branch feed pipes are entirely of copper.

The Main Engines.—In the first case these were three in number, two of which have cylinders 15in. and 25in. by 16in. stroke and run at 167 revolutions per minute. The high-pressure cylinders are fitted with piston valves, and the low-pressure with slide valves. They are controlled by a flywheel governor acting on the high-pressure valves. The governor is fitted with Raworth's patent adjustment for altering the speed while running, and for dividing the load as required between the various machines running in parallel. The low-pressure slide valves are provided with Hackworth's gear for varying the cut off in the low-pressure cylinder whilst running, so that the engines may be operated with the best results for any load. We illustrate one of these engines. The small engine is similar to the larger engines, except that an Acme throttle-valve governor is used. The cylinders are 11in. and 18½in. diameter by 12in. stroke, and the speed 200 revolutions per minute.

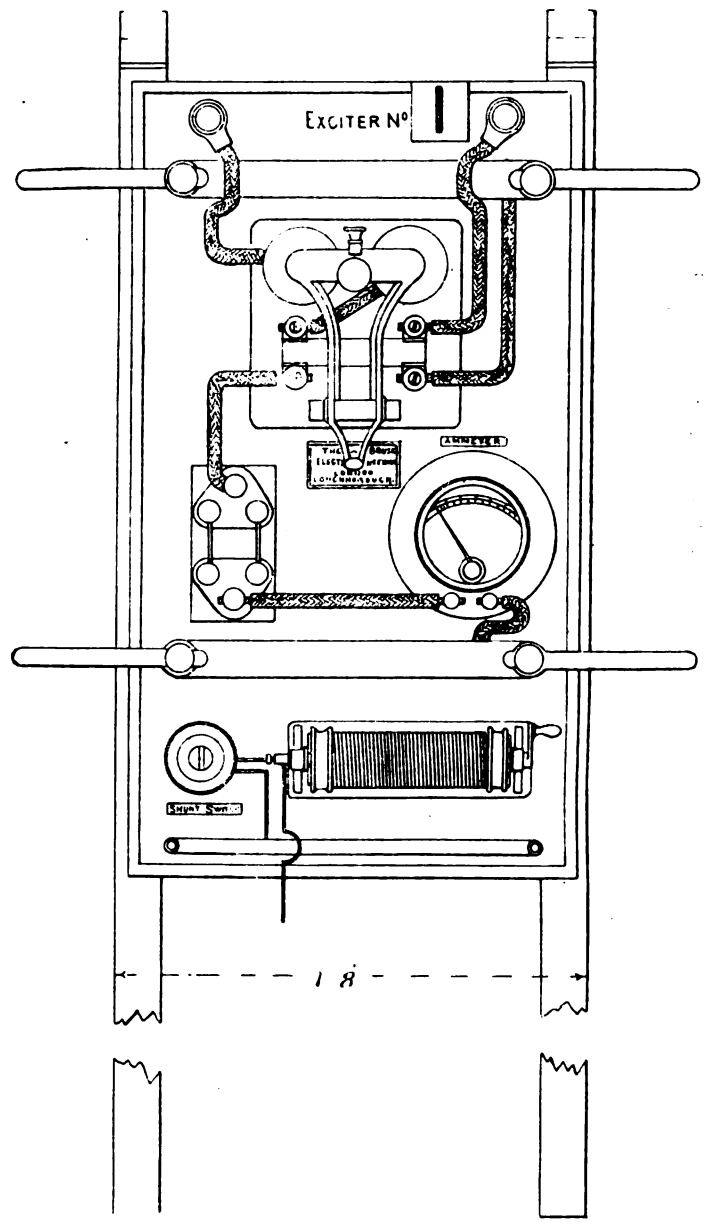
Alternators.—The alternators, which are of the well-known Mordey-Victoria type, are driven from the above engines by means of separate cotton ropes. Two of these (see illustration) run at 430 revolutions, and have a capacity of 100 kilowatts each, whilst the third runs at 600, and works up to 50 kilowatts, the pressure being 2,000 volts.

Exciting Plant.—To obviate running two engines during the light load, there is fixed on the shaft of the 50-kilowatt alternator a small two-pole exciter. The exciting omnibus bars are fed from two Victoria dynamos, each coupled direct to a 6in. by 5in. Brush engine running at 400 revolutions, and each capable of an output of 4,500 watts at 65 volts; this is sufficient to excite generating plant up to about 500 kilowatts capacity.

Switchboards.—The "Unit" system, introduced by the Brush Company, has been carried out very thoroughly in this station; each exciter has a switchboard with ammeter and zero cut-out arranged for running the compound-wound exciters in parallel on to the exciter omnibus bars. Platinoid resistances wound on bars of slate with a sliding contact are used in the shunt circuit for regulating the pressure of the exciters, and through them of the whole station. The station voltmeter is fixed immediately over these resistances. The field of each alternator is connected to the exciting mains by a special switch, which puts in a water resistance when the circuit is being opened, and so obviates the effect of suddenly opening the field circuit. Opposite each alternator there is a board containing double-pole high-tension

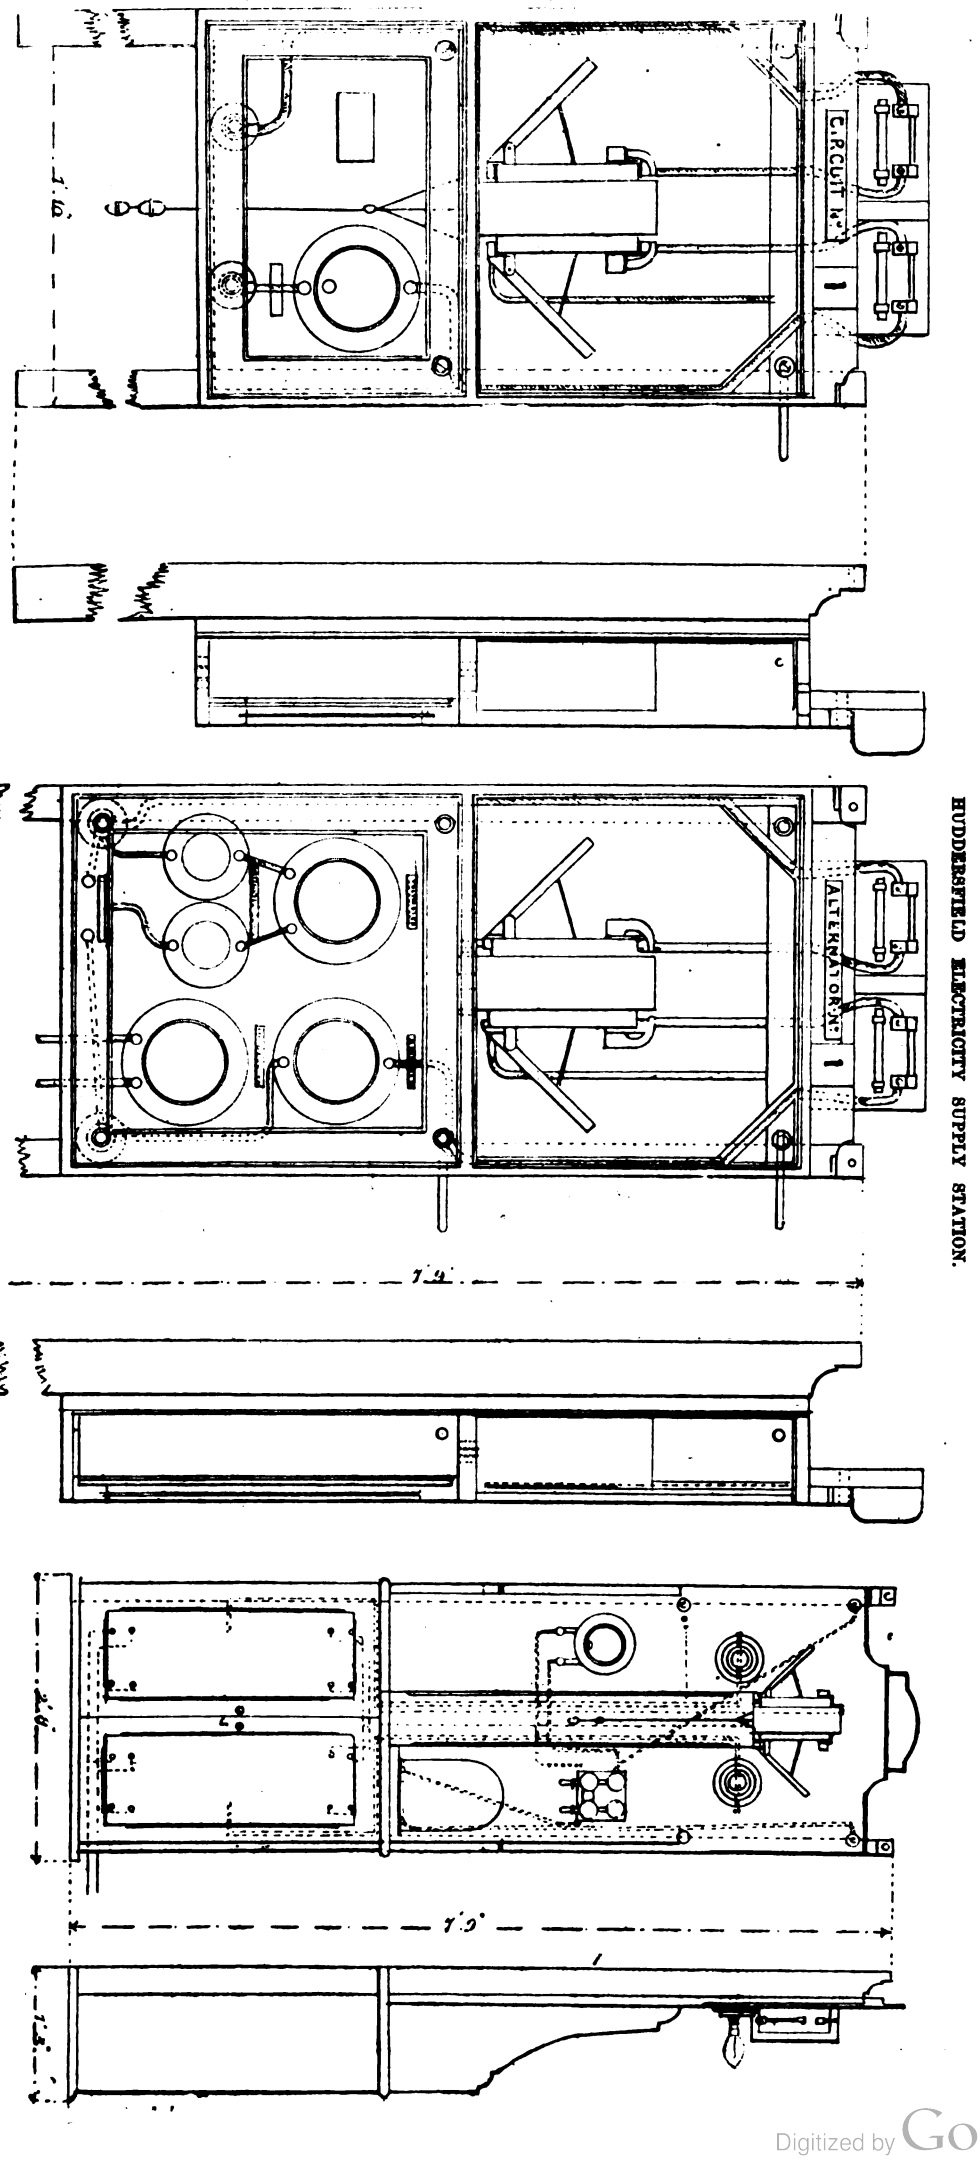


Plan of Chimney—Huddersfield.



Exciter Board—Huddersfield

Digitized by Google



Alternator, Circuit, and Synchroniser Board.

HUDDERSFIELD ELECTRICITY SUPPLY STATION.

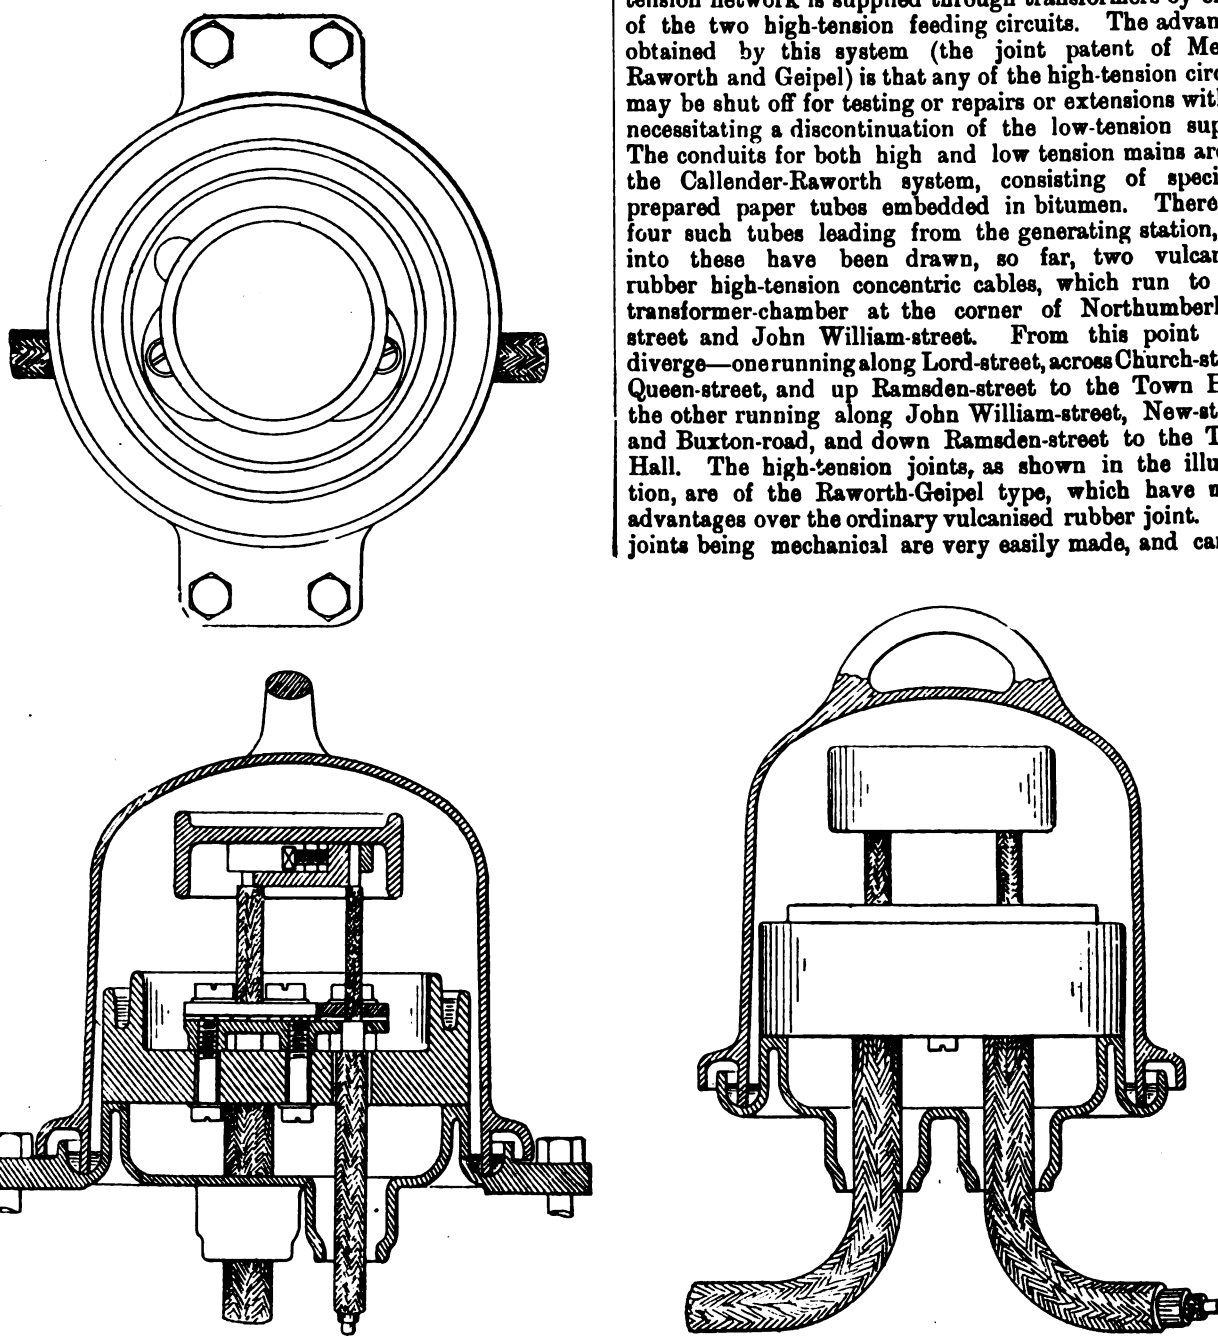
Digitized by Google

fuses and switches for connecting the machine to the station omnibus bars, and also an alternate-current ammeter, a voltmeter on one coil of the armature, and an ammeter on the field circuit. There is also a small double-pole plug switch for connecting the alternator to the synchroniser. The synchroniser board contains two synchronisers and lamps, together with double-pole switches for connecting the synchroniser to the station omnibus bars. It also carries the main station ammeter and the main station recording meter, which is of the Shallenberger type, while provision is made on the board for a recording watt-meter. After passing through this board from the alternators the omnibus mains proceed to the circuit boards, of which at present there are two; each carries an ammeter and double-pole high tension switch and fuse. One example of each of the above boards is illustrated. It will be seen that this system allows of the addition of any number of exciters, alternators, circuits, and their corresponding boards, without in any way interfering with the existing arrangement. The switchboards are all operated from a gallery running along two sides of the engine-room, and are so placed as to correspond with the machines to which they belong. Access to the gallery is obtained directly from the offices of the electricians, which are on the first floor, or by circular stairs from the engine-room.

Testing Wires.—From the testing-room are run wires to various parts in the machine-room, where terminals are fitted for rapid connection with any of the machines and circuits. A very complete set of testing instruments has been provided.

The whole of the engine-room plant has been manufactured by the Brush Company at their Loughborough works.

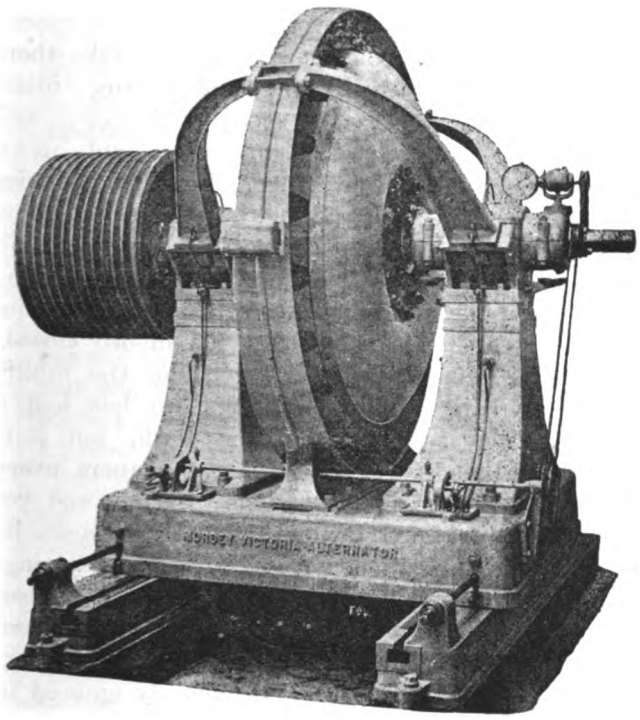
Distribution.—The distribution is effected by low-tension distributing mains, 100 volts pressure, running from the transformer sub-stations, which are situated at convenient points in the town, while it is so arranged that the low-tension network is supplied through transformers by either of the two high-tension feeding circuits. The advantage obtained by this system (the joint patent of Messrs. Raworth and Geipel) is that any of the high-tension circuits may be shut off for testing or repairs or extensions without necessitating a discontinuation of the low-tension supply. The conduits for both high and low tension mains are on the Callender-Raworth system, consisting of specially-prepared paper tubes embedded in bitumen. There are four such tubes leading from the generating station, and into these have been drawn, so far, two vulcanised rubber high-tension concentric cables, which run to the transformer-chamber at the corner of Northumberland-street and John William-street. From this point they diverge—one running along Lord-street, across Church-street, Queen-street, and up Ramsden-street to the Town Hall; the other running along John William-street, New-street, and Buxton-road, and down Ramsden-street to the Town Hall. The high-tension joints, as shown in the illustration, are of the Raworth-Geipel type, which have many advantages over the ordinary vulcanised rubber joint. The joints being mechanical are very easily made, and can be inspected by merely lifting off the cover, while the cable may be easily disconnected for testing. As the jointing of the high-tension mains is a somewhat vital part of the circuit, it speaks well for these joints that not one of them has caused the least trouble. At present only four transformer stations are in use. They are equipped with Mordey-Victoria transformers, mostly of the 18-kilowatt size, all of which have been constructed with earthed shields between the primary and secondary windings to satisfy the Board of Trade requirements as to safety. The low-tension network which is fed from these sub-stations serves the principal streets in the town. The length of the low-tension mains at present laid is about 10,000 yards, and the conduit about 15,000 yards.



Raworth and Geipel Joints—Huddersfield

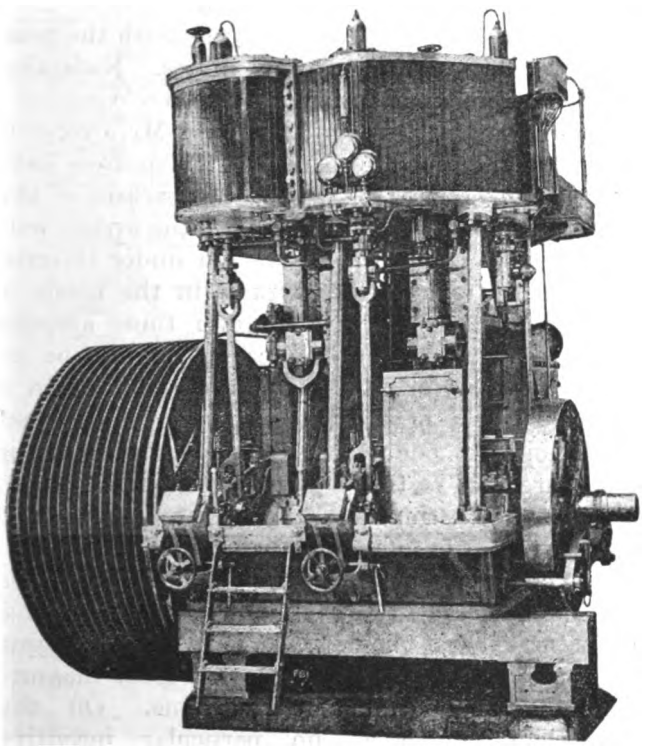
Digitized by Google

The light has been taken up in a most satisfactory manner; indeed, so great has been the demand that before the station was put to work an order was placed with the Brush Company to double the capacity of the plant in time for this winter's supply. The new plant, which we illustrate, consists of a 250-kilowatt Mordey-Victoria alternator,



Mordey-Victoria Alternator - Huddersfield.

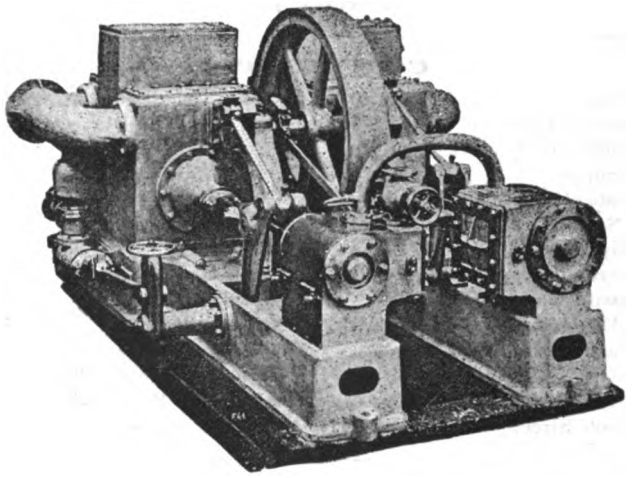
running at 300 revolutions, driven by means of cotton ropes, and a Brush engine, having cylinders 18in. and 33½in. diameter and a stroke of 20in.; it is in most respects similar to the smaller engines already described, and runs at 150 revolutions per minute. A third high-tension main



Vertical Compound Condensing Engine—Huddersfield

is about to be laid to meet the extending demand, and the high-tension mains have already been extended to the residential district up the New North-road. It is interesting to note that the outlying districts in Huddersfield are already being supplied, while in the neighbouring town of Bradford, where the low-tension system alone has been in use several years, the supply is not yet available in the suburbs.

In conclusion, it should be stated that the whole of the works have been carried out under the able supervision (on behalf of the Huddersfield Corporation) of Mr. A. B. Mountain, borough electrical engineer, and generally under the control of the Electric Lighting Committee, the individual members of which have taken the greatest interest in the scheme throughout; while the general design and the equipment of this interesting station has been in charge of the Brush Company's contract department and staff, under the control of Mr. W. Geipel, their superintending

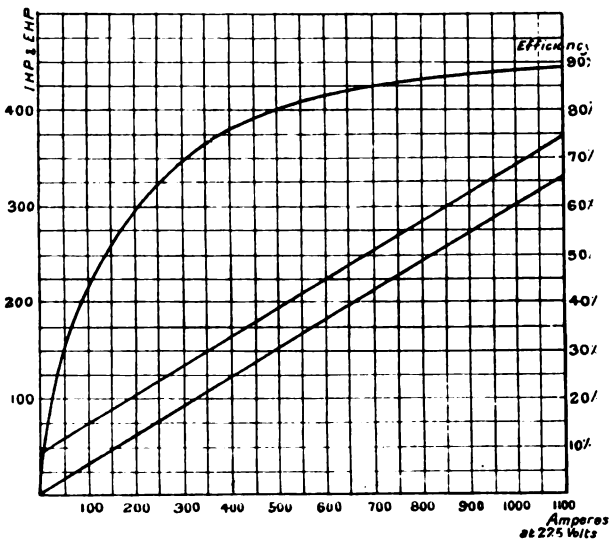


Raworth's Compound Combined Air Circulating and Feed Pumps—Huddersfield

engineer, seconded by Mr. S. A. Mahood as resident engineer.

TESTS OF A SIEMENS-WILLANS SET.

The test of a combined Willans-Siemens set intended for the Glasgow Corporation was recently carried out at the works of Messrs. Willans at Thames Ditton under the supervision of Prof. A. Kennedy, F.R.S. The accompanying table and curve show the remarkable efficiency of



Efficiency Curve, Siemens-Willans Set.

this plant. After allowing the ordinary losses under working conditions, it is difficult to believe that much further advances in efficiency can be obtained. The greatest praise must be given both to the makers of the dynamo and of the engine in having achieved such results.

ANY LESSONS?

Some patriot in the pride of English achievements is stated to have said we had nothing to learn from the States, and he might have added with equal truthfulness, from anywhere else. Fortunately, these statements—after dinner usually—are here taken for what they are worth, which is not much; but some of our cousins are apt to take them seriously — or, rather, the enterprising interviewer wants to make sensational copy—and circulation is given to something said in a jocular way, or not said at all. Mr. Preece denies that he ever said such a thing, but those who know him had no need of the denial—they always took the statement as far-fetched and improbable. Mr. Preece is a man who has throughout life kept his eyes and ears wide open—and his mouth closed. The latter remark, when we consider the multiplicity of papers and discussions he has had a hand in, may seem wide of the mark, but it is true nevertheless. You may read papers every day and take part in discussions as often, and yet in certain directions for all practical purposes be as silent as the grave. With regard to learning, there is always something to learn, and it is absolutely certain that we have learnt many things from America just as America has learnt many things from us. One great fact is generally ignored in the comparison between the two countries, and that is in the vast difference existing in the conditions which have to be considered. In some of his remarks we do not think Mr. Preece sufficiently took this into account in his paper read last night before the Institution of Electrical Engineers, a portion only of which we are able to give in to-day's issue. In this paper, Mr. Preece sets forth the position of applied electricity in the States. Naturally, somewhat minute attention is given to telegraphy—not more than it deserves; but here Mr. Preece is altogether a critic, and his readers and hearers have little or no chance to make a comparison of the system as holding in the States with the system pertaining in England. Here we are under Government control; there the work is in the hands of private companies. Now, however these systems may be compared, the balance will always be in favour of Government control, especially when a company has a practical monopoly. That is our conclusion, and one of our principal arguments in its favour would be that a gigantic system of land or ocean telegraphy run by a company is too often, if not in every case, run more directly for the benefit of a certain clique of individuals than for the benefit of the shareholders or the community at large. It is but natural that it should be so. Anyhow, the exact position of the company depends in a great measure upon the self-control of this clique. On the other hand, there is no particular incentive upon Government officials to progress. They too frequently say, We have done very well hitherto—why change? The inner working of our postal telegraphs has been different from this, and we can only attribute that difference to the ability and energy of the responsible officials. We are undoubtedly, telegraphically, in a position ahead

Digitized by Google

of any other country under the sun. That position, we contend, is in no small measure due to Mr. Preece, whose eyes, ears, and mouth, as we say, have been under control. What he and his colleagues have seen and heard has been carefully tested, and if something else has been adopted, there always seems to be a good reason for it. Take, for example, the use of accumulators *v.* dynamos. The former prevail here, the latter in America; but we venture to think the English officials are correct, and the Americans made a jump in a direction which will have to be changed. Still, admitting our system to be better, there is something to be learnt from American energy and push; and when we look from telegraphy to telephony we are not in the running. Here, as there, the matter has been in the hands of private companies—and who can say that a clique or cliques did not here for years run the system to further their own ends? The subject is a nauseous one—let us leave it. There is, however, one point to which we ought to direct attention—the disturbances caused in telephony by electric traction, and the remedies taken both by telephone and traction companies to prevent it. A little give and take added to a little forbearance will do wonders; but once get the backs of contending parties set up, remedies, of course, are difficult to find. Metallic circuits, on the one hand, and heavier conductors with earthing the negative poles, on the other, have reduced the troubles, and like those arising from electrolytic action, there is no valid reason why traction and telephony should not rest lamb-like side by side. Oh, that we could say like this: "The present generation in America has grown up with the telephone. It has become a factor of business, and absolutely essential to the transaction of that business. The working is excellent, and they are alive to the necessity of maintaining its efficiency at the very highest point. Education is complete not only of the staff, but of the customer. I find a group of highly-educated, clever, young electricians being engaged and encouraged by the telephone companies." Mr. Preece's paper goes on to discourse upon the Chicago Congress, the exhibition, lighting, and traction, and in each direction no doubt we may find something to learn and something to impart. Thus, for example, while we can point to a Siemens-Willans set of electric lighting plant for a central station (Glasgow) giving so high an efficiency as 88 per cent. at full load, it must be admitted that such engines and dynamos are hard to beat. Mr. Preece's statements will be carefully studied, and if points are noted to our disadvantage, no doubt efforts will be made to remedy the remissions, and that we shall allow no one to claim advantages which English practice cannot give. It must not be forgotten that the enormous development both of traction and of lighting in the States is principally due to the peculiar conditions existing. No artificial light and no system of town traction make it easy to introduce either electric lighting or electric traction. It is not too much to say, however, that the Americans are wise in their generation; and though they will take an imperfect system of lighting or traction rather than nothing, and prefer it rather than be kept waiting, they will not be satisfied with the imperfect when better can be obtained. Thus the rapid progress made—they take the best they can get, and ask for something better, which they take as soon as they can get.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ENGLISH CARBONS.

SIR,—Our attention having been drawn to a statement made in several of the electrical newspapers that "all carbons used in England for arc lighting have hitherto been imported from abroad," we should be obliged if you would correct this statement, which is inaccurate.

We have been engaged for over 15 years in the manufacture of carbon rods for electric lighting. These carbons have been made under English patents, and at our works at Silvertown we have a complete plant in daily operation for the production of such carbons for electric lighting.

We trust that you will insert this contradiction in an early issue.—Yours, etc.,

WM. J. TYLER, Secretary.

India Rubber, Gutta Percha, and Telegraph Works Company, Limited, 106, Cannon-street, London, E.C., January 22, 1894.

INSTITUTION OF ELECTRICAL ENGINEERS, Jan. 25.

At last night's meeting of the Institution, the following candidates were ballotted for:

Foreign Members.—Oscar Bihet, director of the Société St. Leonard (Outils), 1, Rue St. Leonard, Liége; Samuel G. Neiler, Chicago, Illinois, U.S.A.; Richard Henry Pierce, Chicago, U.S.A.

Associates.—Henry John Andrews, 184, Iverson-road, West Hampstead, N.W.; Philip Francis Anstruther, Fernando de Noronha, Brazil; Frank Ayrton, Preston Villa, Otter-street, Tristis Park, Derby; H. Brookes-Edwards, Cardigan Works, Wakefield, Yorkshire; Cox Pearson Chambers, superintendent Government Telephones, Antigua, Leeward Islands, British West Indies; William Challoner, Blackpool; George Granville Clarke, 6, Smith-square, Westminster; William Henry Eaves, Volt Works, Ryley-street, Coventry; Augustus Eckstein, 45, Chapel-street, Salford; Michael Birt Field, Claremont, Woodberry Down, N.; Charles Lewis French, 46, Bayston road, Stoke Newington; John Grant, inspector Government Telegraphs, Cape Town, S.A.; C. J. Whistler Hanson, 16, Featherstone-buildings, Holborn, W.C.; W. Marshall-Huskisson, 127, Ladbrooke-grove, W.; William John Kelly, 58, Bread-street, E.C.; John William Leyshon, 32A, Lower Cathedral-road, Cardiff; Alfred Marshall, 31, Ball-street, Kensington; Alfred Ernest Le Rossignol, Alton Cottage, Mount-street, Old Charlton, Kent; Thomas William Skinner, 6, Carlton House-terrace, London; Frank H. Starling, 35, Queen's-walk, Nottingham.

Students.—Gerald Carlyle Allingham, Eldon House, Lyndhurst-road, Hampstead, N.W.; Frank Armstrong, Faraday House, Charing Cross-road, W.C.; Walter James Belsey, "Clarville," Albany-road, Chorlton-cum-Hardy, Manchester; James Herbert Edwards, Faraday House, Charing Cross-road, W.C.; William R. Elliott, City and Guilds Technical College, Leonard-street, Finsbury; Louis Henry Euler, Faraday House, Charing Cross-road, W.C; William Fennell, 1, Ferndale-road, Leytonstone, E.; Herbert Francis Hunt, 14, Thistlewaite-road, Clapton, N.E.; Lionel C. Johnson, 13, Lorn-street, Chorlton-on-Medlock, Manchester; Albert Henry Joyner, 26, Dorothy-road, Clapham Junction, S.W.; Philip E. Lewis, 3, Tetcott-road, King's-road, Chelsea; W. M. Nelson, 18, Pyrland-road, Canonbury, N.; William Samuel Parsons, Faraday House, Charing Cross-road, W.C.; Eliot Charles Pringle, Faraday House, Charing Cross-road, W.C.; John Thomas Redmayne, 71, Albion-street, Leeds; Charles Alfred Spon, 125, Strand, W.C.; Frederick William Baron de Tuyll, 51, Earl's Court-square, W.

The following paper was then read:

NOTES OF A TRIP TO THE UNITED STATES AND TO CHICAGO, 1893.

BY W. H. PREECE, C.B., F.R.S., PAST-PRESIDENT.

In 1877, together with Mr. H. C. Fischer, I made an officia and thorough inspection of the telegraphic system of the United States and Canada, and the lessons of that journey were re-

Digitized by Google

ported to this Institution on February 13, 1878. The results of that trip were the introduction of the telephone, the practical application of quadruplex working, the adoption of sound reading in our telegraph offices, the disappearance of the Morse recorder, and the more general assimilation of the methods of working in the two countries. In 1884, as a member of the British Association, I again visited Canada, and made another tour through the States, reporting my observations to the Institution on December 11, 1884. The chief result of this second trip was the introduction of the multiplex system of working of Mr. Delany, now so much in use amongst us, and doing splendid service with many of our chief towns; hexode working, six messages in any direction are simultaneously transmitted between London, Brighton, Bristol, Birmingham, and other commercial centres. The telephone was found fully developed, and firmly rooted as an invaluable aid in domestic and business requirements. The electric light was making great advances, especially as the illuminant of public streets and ways, to the great advantage and safety of the public, but electric railways and the transmission of power were only just looming in the air in an extremely tentative and experimental stage. Now I am able to report another tale of a 10 weeks' trip taken in August and September last over much the same ground, but with two *pièces de résistance* thrown in—a visit to the great World's Fair, and the holding of an electrical congress at Chicago.

I. Telegraphs.

The telegraphic system in the United States is in the hands of two great private telegraph companies—the Western Union Telegraph Company and the Postal Telegraph Company. The Western Union Telegraph Company, which is by far the larger of the two, is a gigantic undertaking. It is a congerie of at least 500 other companies which have been purchased, absorbed, or amalgamated from time, and it is also closely connected with virtually all the railways in the States. This connection with the railway companies gives it a very prominent and commanding position over its rival. In order to show the progress made since 1884, and the present condition of the business, I give the following table:

Particulars.	1884.	1893.	Great Britain, 1892.
Miles of poles and cables	145,037 ..	189,936 ...	33 689
Miles of wire..... ...	450,571 ...	769,201 ...	207,231
Offices	13,761 ...	21,078 ...	8,537
Messages	42,076,226 ...	66,591,858 .	72,302,556
Capital	$80,000,000 ..	$123,000,000 . .	£10,130,820
Receipts.....	$19,632 940 ...	$24,978,442 . .	£2,486,791
Expenses	$13,022,504 ...	$17,482,405 ...	£2,470,839

The Postal Telegraph Company is a very much smaller concern. It has virtually come into existence since my previous visit, for when I was last in the States it had just commenced its operations, and it only possessed 1,500 miles of line and 4,260 miles of wires. It is a company which has been promoted, not so much to attack the Western Union Company, as was the case with all previous competing lines, but to establish a collecting company for the cable business which is in the hands of the Commercial Cable Company. The present position of the Postal Telegraph Company is as follows: Miles of line, 15,997; miles of wire, 99,664; offices, 2,664 (of this number 860, or nearly one-third, are situated out of the States, in Canada and elsewhere); messages, 9,335,291. The enterprise in telegraph work is evident at once on landing in New York. Every passenger on landing at the dock stage is approached by a messenger from one or both companies soliciting messages; and on all stages, except that of the Cunard Company, one or other of the telegraph companies has succeeded in establishing an office. The business done at these offices is very great, as, when facilities are thus given to passengers to send messages, nearly everyone wires home his or her safe arrival. This enterprise is evident everywhere. The blue and white sign of the Western Union Company, which is extremely prominent, is found in every hotel, at all railway stations, and in large cities, and is as abundant as the post office sign is in England. At Long Branch, the Brighton of New York, where I spent two or three very pleasant days, there were no less than 19 offices belonging to the Western Union Company, and all paying. There were 20 offices in the World's Fair alone, and 70 hotels in Chicago have Western Union offices in them. Competition is intense, but there is no war of rates. A general tariff has been agreed upon, and the only rivalry that exists is in the collection and transaction of business. Dividend-earning being the chief end aimed at, only paying commercial stations are properly served. Social and domestic telegraphy is practically ignored, and sparsely-populated districts are very inadequately provided for. Hence in the United States telegraph business is neither so general nor so cheap as it is with us. The average price received per message is 15¾d., as against 7·7d. earned by us. On the other hand, however, it must be remembered that their mean distance is far in excess of ours.

Construction of Lines.—I inspected considerable lengths of the line work constructed by each company, and drove over many miles of a new road line passing through Connecticut. In this direction American electrical engineers have been very much behind us. They have not built their lines so solidly, nor have they followed true engineering principles in the same way that we have. As a rule, their lines are extremely irregular, being badly constructed with poles that we in England would not look at; but recently, owing to the difficulty in finding fresh routes, the growth of the number of the wires, and to the absolute necessity for accuracy of workmanship for securing silence on telephone lines, great improvements have been made, and some of the trunk lines put up by the telephone companies, and the new trunk line put up by the Postal Telegraph Company, will compare very favourably with our best modes of construction. The telephone line to which I have alluded above consists of 16 arms, each carrying 10 wires, or 160 wires in all. The poles are 60ft. high, and are placed 100ft. apart. The arms are of pine, and their scantling is 3½in. by 4½in., and they are 10ft. long. Owing to the use of wooden pins they are bored with holes 1½in. in diameter. This weakens the arm, and I observed two instances where arms were broken. A 6ft. arm bored for four insulators costs 15 cents, which is cheap compared with the price we pay. But they are undoubtedly weak, and not to be compared with the oak arms that we use. As a rule, the poles number 40 to the mile. They are generally of cedar, but sometimes of chestnut. The cedar poles come from Canada and Michigan. Each 25ft. cedar pole costs 2·25dol., and is said to last 15 years without preparation. The chestnut pole is a little cheaper, and it lasts only 10 years. It is extremely irregular in shape. American engineers do not adopt the same plan that we adopt in the erection of arms. They are fixed any way, but generally on the modern lines they alternate on each side of the pole. This is done under the impression that it adds strength to the line. I do not know why it should. (We invariably fix the arms on that side of the pole facing London.) Every fifth pole is earthed as a protection against lightning. (We earth-wire every pole.) Stays are very little used, indeed, but on new lines they have longitudinal stays in the direction of the wires, one end being fixed at the foot of one pole, and the other end at the top of the next pole. These are called "head guys," and are frequent. Iron poles are used only for electric railways. These are very substantial, and look very well. They are made in three sections of simple iron tubes, either 6, 5, and 4, or 5, 4, and 3 inches in diameter respectively. Pole roofs are not used as with us, but the poles are tapered off to throw off the rain. Neither the Western Union nor the Postal Telegraph Company adopt any system for preparing their timber to resist decay. My attention had been called to a system of artificial seasoning called "wood vulcanising," and it was reported that this system had been adopted by the Western Union Company. I found this was not true. The Western Union Company had experimentally tried the system on some wooden troughing employed for the protection of their pneumatic tubes underground; but the process was so expensive, and the advantages so doubtful, that they do not apply it to their poles or their arms. Copper wire is very much used on telegraph and telephone lines. I saw in the exhibition at Chicago a form of wire called "tempered copper." This is said to be extremely strong and hard, but it is evidently an alloy of copper, for its resistance is high. I was surprised to find that a compound wire 1·7 ohms resistance per mile, put up by the Postal Telegraph Company in 1883, is still in use, and working well. Our experience of the durability of this wire was disastrous.

Underground Work.—Underground work was scarcely started in the States in 1884, but now, owing to peremptory legislation on the part of the municipalities, it has made very rapid progress. Underground work in the cities of the States has become general, with great advantage to the public, and also, as they have come to acknowledge, to the companies themselves. The only exception to this rule that I heard of was at Boston, where complaint was made that their underground system had been much disturbed by "wash-outs." These "wash-outs" are freshets, or great floods, tearing up the line and carrying away the pipes and wires. The system of underground work adopted by the telegraph companies in America does not differ much from that adopted by us, excepting that they do not use gutta-percha, owing to its high price. They are using very largely a cable similar to the Fowler-Waring cables, and also kerite-covered wire. Kerite is a form of vulcanised indiarubber.

Offices.—Not much change has been effected in the mode of fitting up offices. Glass of the best quality is used very much indeed—doors, partitions, boxes for the collection of messages, are all made of thick glass. This looks very clean and nice, and is certainly effective. There is an extremely efficient mode of collecting and distributing messages in the Western Union offices at New York and Chicago. Endless cords are kept in motion by means of small electric motors, and these cords transport small metal carriers somewhat similar to those we use in our pneumatic tubes. Before leaving New York I saw an improvement on this by which messages can be picked up as by the finger and thumb from the desk in front of each operator. They also have in use a system by which

Digitized by Google

messages, envelopes, slips, etc., are conveyed by broad continuous leather belts, 8in. wide, kept in rapid motion by motors, and upon which the messages, etc., are laid, and carried to the point desired. Each company has adopted a uniform and pretty-looking box for its office in the hotels. American hotels differ from ours in this: the hall of an hotel is usually open to the public, and no hotel that I entered was unfurnished with a telegraph office. I have mentioned that there were 70 hotel offices in Chicago. In fact, hotel proprietors court the presence of a telegraph office. Space is usually accorded free, and board is also provided for the operator. In some places, like the Palmer House Hotel, at Chicago, which is a great business centre, a very high rent is demanded; but generally speaking no rent at all is paid. At the hotel I stayed at in Chicago—the Lexington—each company had an office in the hall, the rivalry that exists between the two companies taking the form of each striving to work with the louder sounder. The louder was that of the Postal Telegraph Company, and when I asked the operator why he allowed his instrument to make such a row, he replied, "We must beat the Western Union Company, anyhow." At Fort Sheridan, a military station about 20 miles away from Chicago, the Western Union Company opened an office, although the place contained only 1,000 soldiers. The office was worked by the soldiers, and I was assured by the company that they found it pay well. The common system in the States is to tile the floors of their telegraph galleries, and not to board them. Fireproof channels, or conduits fitted with slate tops, are arranged about the office for the distribution of the wires. Lockers for coats and hats are roomy and well made, and ample in the supply. At Chicago they are of open ironwork, very neatly made, 6ft. 6in. high, and 28in. by 8in. in sectional area. Four men, each of whom is supplied with a key, use such a locker. Great advantage is said to arise from the use of these open lockers in wet weather, and they are worth our own consideration. The use of bicycles for messengers is very prevalent in the States. Batteries at all the principal offices in the United States are gradually disappearing. The current for working the circuits is being supplied from dynamos, or from the electric lighting mains. In New York from 30,000 to 40,000 cells have been replaced by dynamos. At Boston 10,000 cells, which cost probably £4,000 per annum to maintain, have been replaced by current derived from the electric light mains at a cost of £600 a year. It must be remembered that the American telegraph circuits are worked entirely on the closed-circuit system. They use immense cells, and their cost of maintenance is excessive. We cannot compare their system with ours in this respect, for we use open circuits; and the maintenance of our batteries is certainly, cell for cell, not more than one-fourth or one-fifth that of the United States form of battery. In New York, the Western Union Company have a special plant of 51 small dynamos; in Chicago, they have 46. The Postal Telegraph Company in New York are also using dynamos, and in their new station which is being built they are supplying what they believe to be an improvement on the system adopted by the Western Union Company. We have shown in England that the use of dynamos, owing to the variation of current, is not suitable for high-speed working, and I much prefer the plan that we have adopted with so much success in working our continental circuits—namely, the use of accumulators. Accumulators have an immense advantage over dynamos: they store up energy, so that in the event of any accident or breakdown of machinery the accumulator maintains the circuits working. The accumulator is not in motion. There is no machinery to fail or to break. There is nothing to stop and little to get out of order. But the chief advantage of the accumulator is the absolute steadiness of its voltage. There is also economy in capital expenditure, and I am quite convinced that the Western Union Company in New York would have effected considerable economy if they had used accumulators charged by the electric lighting plant, instead of supplying the elaborate series of engines and dynamos now working their circuits direct. At Boston and other stations a very well-made and well-designed motor-dynamo is supplied by Messrs. Crocker-Wheeler. They are primarily motors worked on the 110-volt electric lighting service, driving a small dynamo, and they transform this down to a voltage which will charge any number of cells required. This system is in use by all the telephone companies, and, as I will point out when speaking of telephones, the service is much improved by the use of accumulators thus charged.

Apparatus.—I observed little or no progress in the form of apparatus used. In neither company has there been any advance made on the systems in use in 1884. Duplex and quadruplex working are principally relied upon, while on the long-distance lines Wheatstone working is gaining ground and being much more used. The only novel mode of working that was brought to my attention was a system of working cables automatically. This system has been threshed out by Mr. Wilmot at Waterville, and adopted by the Commercial Cable Company, but it has been very much improved upon by Mr. Delany, the inventor of our multiplex system. Typewriters have become quite common. The rule is for an operator to have his own machine. The Postal Telegraph Company use this system more largely than the Western Union Company. The latter company employ it invariably for their Wheatstone and other news circuits, but the Postal Telegraph Company use it very largely on all circuits; and I watched many operators taking off messages by ear and typeprinting them at the same time, and in all cases the typewriting machine held the sounder well in hand as regards speed. The working of the Wheatstone system between New York and Chicago is admirable. The grand total of messages handled in one day on this circuit is certainly astonishing; 4,211 messages have been passed between these two places on one circuit in a day—a number that we can scarcely hope to rival. The reason for this is not the greater speed at which the apparatus is worked—for the speed is less than ours—but to the fact that the business day in the United States extends over a much greater number of hours than with us. The business day in New York commences three hours before that in San Francisco, and the business day in San Francisco extends for three hours beyond the business day in New York. Hence the business day, which in England scarcely extends telegraphically to four hours, in the United States extends probably to 12 hours. Thus the number of messages handled is much greater per day than with us. The advantage of Wheatstone working to the company was illustrated while I was there. On August 29 a cyclone in the eastern part of the States prostrated the poles and wires for miles throughout half-a-dozen States. Three Wheatstone circuits were maintained working—and working badly—between Chicago and New York by means of repeaters at Buffalo and Pittsburg, but on these three circuits 8,693 messages were handled. This was the only means of telegraphic communication between the Eastern and the Western States. Curiously enough, the new and strong long-distance telephone line was not broken down. On August 18, while I was there, I took down as having been sent between 8 a.m. and 5.30 p.m.: forwarded, 1,272; received, 1,889. This work was handled on two circuits, with an average speed of 190 words per minute. The Wheatstone system in the States is much more extensive in the West than in the East. It is giving such good service that it will probably receive considerable additions this year. It must be remembered that between Chicago and San Francisco we are dealing with a distance of 2,500 miles, and on this circuit they were working when I was there at the rate of 110 words per minute. I observed a very high rate of working on some of the quadruplex circuits. I took down these figures at Boston: forwarded, 686; received, 521. This was an ordinary day's work. On another circuit, between 8.30 a.m. and 11.30 a.m., in Buffalo, the numbers were: forwarded, 126; received, 140; on one side of the quadruplex only. I noticed at the Chicago Exhibition, in the French exhibit, a new adaptation of multiplex working by M. Mercadier, who showed in operation 12 working sides. But the working, although interesting, was poor. The reading was done by telephone, and each branch was selected by the sounding of a particular note. The apparatus is not yet in anything approaching a practical stage, but for short lines something may some day come out of it.

Pneumatic Tubes.—The Western Union Company have not extended their system of pneumatic tubes greatly since my last visit. The Postal Telegraph Company are about to use pneumatic tubes for the distribution of their internal work in their new building on a plan somewhat similar to that which we use at our central station. The only novelty in pneumatic tubes that I saw was that on trial between the post office at Philadelphia and a sub-office in Chestnut-street. This is a line of two pipes 6⅛in. in diameter and 5,792ft. in total length—that is, a distance between the two offices of 2,896ft. The carriers are metal cylinders, whose inside dimensions are 16in. long and 5½in. in diameter. They weigh 6lb. each, and carry 120 letters. The carrying capacity of the line is said to be 180,000 letters per hour, but I think this is exaggerated. The time taken by a carrier in transit is 55 seconds, and the air pressure is maintained at 7lb. per square inch. The line has been working since February 17, and it has been used for the transmission of letters, the whole service to this particular sub-office being done through the pipe. The pipe is continuous, and a current of air is constantly flowing through it. Twenty-five horse-power is absorbed in maintaining this current at the pressure required, and the carriers are said to move at the rate of 40 miles an hour. Twenty-five carriers are in use. Unfortunately, while I was there the tube was out of use, for the boilers had broken down. These boilers belong to the Post Office Administration, and were not under the control of the contractors who are carrying out the experiment. It is merely an experiment, but it is an experiment that has been carried out in a very practical manner, and they are threshing out a question that may be of importance. They find that the tube used is too small for their purposes, and they are going to use in future an 8in. tube.

Distribution of Time.—A feature of considerable interest and novelty is the distribution of time by the Western Union Com-

Digitized by Google

pany. Correct time is received every day at noon from Washington. The time-current lasts one second. Time-balls are dropped at Boston, Newport, Woods' Holl, New York, Philadelphia, Baltimore, Washington, Fortress Monroe, Savannah, New Orleans, and Havanna. This current is also distributed by the Western Union Company to subscribers in the principal centres. In New York there are 1,100 subscribers, in Chicago there are 1,837, while in the whole of the western district of the company there are 7,963 subscribers. Each of these subscribers has a special wire upon which the time currents are sent from a master or a controlling clock. The Western Union Company also furnish synchronous self-winding clocks to the subscribers, which are controlled and regulated daily by these time-signal currents. They are wound automatically every hour. The rates for this service are not excessive. Each subscriber is charged 2½dol. per month, while large buildings using five or more clocks get the time signal supplied at 1¼dol. per clock per month. The standard time adopted in 1883 is virtually Greenwich time. It is divided into four sections. The following table will show how far these differ from Greenwich mean time and from each other :

W. long.	Centre.	Actual time.	Name adopted.
0deg.	Navigators' time (Greenwich)	noon	Greenwich time.
75deg.	Washington meridian	7 a.m.	Eastern time.
90deg.	Chicago meridian	6 a.m.	Central time.
105deg.	Denver meridian	5 a.m.	Mountain time.
120deg.	San Francisco	4 a.m.	Pacific time.

Thus the minutes and the seconds are the same as with us. There is no necessity to alter one's watch. Hefner von Alteneck proposes to place clocks in the circuit of an ordinary incandescent lamp, and to wind and control them by a slight change in the current made at the central station once a day. It is surprising what can be done by electricity when it is laid on in a house and served from a central station. Von Alteneck's system was exhibited at the World's Fair.

Conclusions.—It is quite impossible to inspect the telegraph system of the United States and compare it with our own system without drawing comparisons between the way in which the work is done in the two countries. The result of my previous visit was to confirm my view that we do our work better in England than they do in the States. Our apparatus is better, our speed is higher. Messages are handled with greater reliability. A message can be sent and its reply received with certainty in an hour in England. I fancy such rapidity would astonish the users of the telegraph in the States, except those in such busy centres as New York and Chicago, and generally the speculative branches of the community. The domestic telegram scarcely seems to have reached the United States, and this is owing probably to the fact that the districts of private residences, the small towns, and the villages do not possess telegraph offices, unless they are supplied by the railway company at the railway station, or by the Western Union Company, who do the work for the railway company. I fail to see any superiority in the manipulative skill of American operators. They certainly have not made the same advance in technical education that we have, and altogether it may be said that the management of the telegraphs in the States in the hands of private enterprise does not compare favourably with the management of the telegraphs by the State at home. At the same time it must not be assumed, because the Government have advantageously taken the telegraphs in hand at home, that such a process would be possible in the States. In my opinion, it would be absolutely impossible. The Civil Service of the States is in a very chaotic condition. The principal appointments are four-year appointments only, and are filled politically. The principal postmasters come in and go out with each new president. We in England scarcely consider that a postmaster is fit to be a postmaster until he has had many years' experience of the working of the Post Office system. In the States a man is made a postmaster because he has been a political supporter. At one or two offices I found the new Post Office officials absolutely ignorant of simple facts they ought to have had at their fingers' ends. A business like that of telephones or telegraphs can only be conducted properly by those who possess a considerable amount of enterprise, and who look primarily to the necessities of the community. The reason why our post offices and our telegraph offices at home work so well is because the public exercises such a useful and such a determined supervision over the work. The free opening of the Press to complaints; the readiness with which members of the House of Commons ask questions—though at times, perhaps, irritating and vexatious—are undoubtedly good for the service, for they keep us all alive. Such a state of affairs is impossible in the States. The Government of the United States must first reform its Civil Service, and when it gets officials into the service whose tenure of office is secure, and whose zeal is as unquestioned as it is in England, then there will be some chance of their Government acquiring the telegraphs; but under existing circumstances the acquisition of the telegraphs by the Government of the United States would amount virtually to the deterioration of the service. The commercial management is at present, as I have pointed out, characterised by great energy. I do not, however, acknowledge that they show greater energy than we do in England. Competition may make it more conspicuous, but it is not more reaching. Our speculative business, stocks, and racing is done as well as theirs. The management at home is characterised in all particulars with similar energy to that which I observed in the States; and I come back without any views or wrinkles which I think could be impressed with advantage on the commercial or technical management of our system at home, unless it be the encouragement of offices in hotels, for it is found everywhere that a telegraph office at one's door prompts the desire or want to telegraph. The capital of the Western Union Telegraph Company was in 1877 22,000,000dol.; that of the British Post Office was £10,000,000. The capital of the former is now 123,000,000dol., while that of the latter remains virtually the same. Scarcely a single vestige of the old telegraph companies' systems purchased by the State in this country now remains. Whence, therefore, this splendid system of cables, underground lines, and new pole lines in this country, spreading everywhere, and transacting an annual business of £2,500,000, instead of the £600,000 handed over to us? It has all been paid for out of revenue! The Government keeps no capital account. How do we do our work? The proof of the pudding is in the eating thereof. The criterion of telegraph-working is rapid despatch. "Time is our only competitor," said Dr. Norvin Green. The time occupied in its transit from the hands of the sender to those of the receiver is the pudding. The whole of the messages arriving in Newcastle on the morning of January 20 were examined and analysed. The mean time of transit from all parts of the United Kingdom averaged 7·8 minutes. A similar examination at Glasgow on January 15 gave a mean result of 8·7 minutes. This cannot be beaten, and it certainly will not be believed. The late Mr. Patey was once asked why express telegraph service at higher rates was not introduced in England. His answer was: "All our messages are express already."

II. Telephones.

The business of telephony in the United States has made gigantic strides since I visited that country in 1884. The following table will show the position of the industry then and now :

	1884.	1893 (January 1).
Miles of wire	115,255	440,793
Miles of underground wire	Nil	91,463
Telephones in use	325,574	552,720*
Telephone subscribers	123,625	232,140
Number of connections between subscribers and exchange	215 millions	600 millions (est.)
Telephone exchanges	1,325	1,351
Staff employed	4,762	9,970

* This is the total number of transmitters and receivers. According to our system of reckoning, where the two together are considered as one instrument, the number given should be divided by two. Thus for comparative purposes it may be said that the United States has 276,360 telephones in use.

It will be seen that there is a very small increase in the number of exchanges opened. This is owing to the fact that hitherto there has been a tendency to centralise the exchange work, and while many exchanges have been abandoned, the small increase is due to the fact that many new exchanges have been opened. It will also be noticed that in the States they have gone in very largely for underground work. This has been forced upon them by municipal action. In addition to this, the companies themselves have been compelled by the indifferent working of their systems to fall back upon the metallic circuit, and now there are 23,053 metallic circuits in use. In New York 62 per cent. of the circuits are metallic, in Buffalo 77·84 per cent, in Boston over 50 per cent., in Chicago 20 per cent., and in Brooklyn 60 per cent. The business of telephony in the United States is a gigantic monopoly in the hands of the American Bell Telephone Company, whose headquarters are at Boston. This company owns more than one half the stock in every telephone company in the States. It holds itself the whole of the stock of what is commonly known as the Long-Distance Telephone Company, but which is really entitled the American Telephone and Telegraph Company, and thus by having control of the stock in every company it maintains the power and monopoly. The advantage of this monopoly is the establishment of a uniformity of working and practice that is highly and extremely beneficial. The form of apparatus used, the mode of working, the details of construction, and all the methods in use are dictated from Boston. The result is little or no friction; and while each independent company is self-managed and self-contained, nevertheless it is subservient to the direction and control of headquarters at Boston. There is no divided responsibility in the United States. Every town has but one system. The result is that the service is thoroughly and perfectly performed. In those parts of the country where metallic circuits have not yet been adopted there may be defects in working, but these are rapidly being removed, for the benefit

Digitized by Google

derived from metallic-circuit working is being felt everywhere in the United States.

Exchanges.—The modes of working may be divided into three classes: (*a*) That dealing with local subscribers alone working upon a single exchange; (*b*) that dealing with trunk working between exchanges in one town or district; and (*c*) that dealing with long-distance speaking, such as that between New York and Boston, New York and Philadelphia, New York and Chicago. I visited three exchanges at Chicago, one at Buffalo, one at Boston, and three in New York, and I looked very thoroughly into the working of each system. While I did not think that any of their local working is done any better than, if as well as, the local working on our own exchange at Newcastle-on-Tyne, there is no doubt that in their trunk working, both for inter-exchange communication and for long-distance working, they are far ahead of us in England. The prevailing switch in the United States is the multiple board, made by the Western Electric Manufacturing Company. The largest board in the world is one which I carefully examined at the Cortlandt-street Central Exchange in New York. It has a capacity for 6,000 subscribers; it is 263ft. long, and is divided into 40 sections. One operator handles 60 subscribers. There are 260,000 holes, or "jacks," as they are called in the States, while in fitting up this switch 780,000 soldered joints were made. It is found in the States that multiple boards can become too large, too unwieldy, and they introduce troubles of their own that have to be remedied. These defects are aggravated when there are several exchanges in the same city. In Chicago Main Exchange 25 per cent. of the business, in Harrison-street Exchange 94 per cent., is trunked out. The average trunking is 50 per cent. A multiple board is, therefore, useful for only 50 per cent. of the work done.

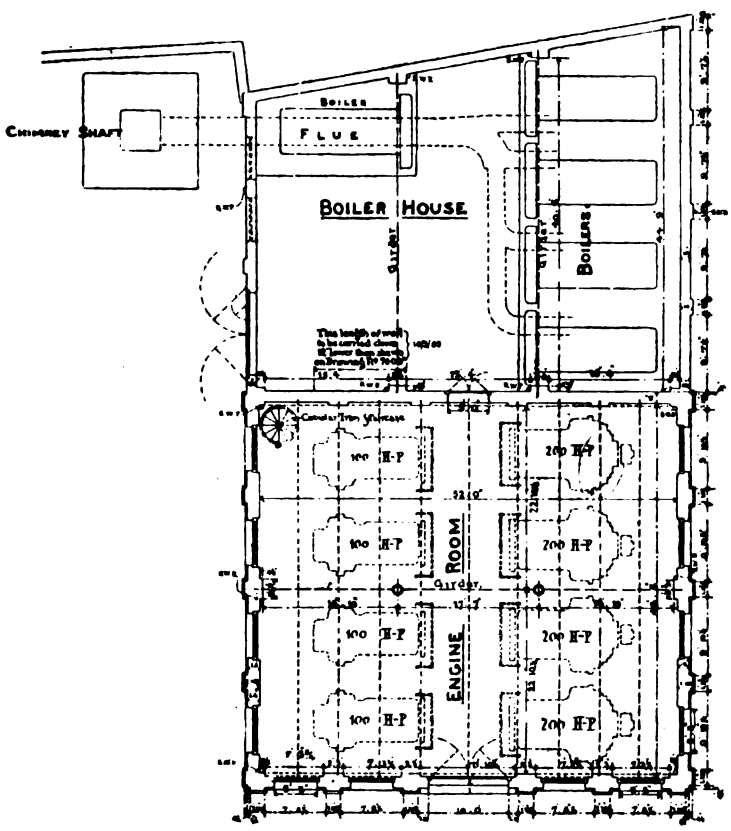
(*To be continued.*)

THE ELECTRIC LIGHT INSTALLATION AT GREAT EASTERN RAILWAY TERMINUS, LIVERPOOL STREET.

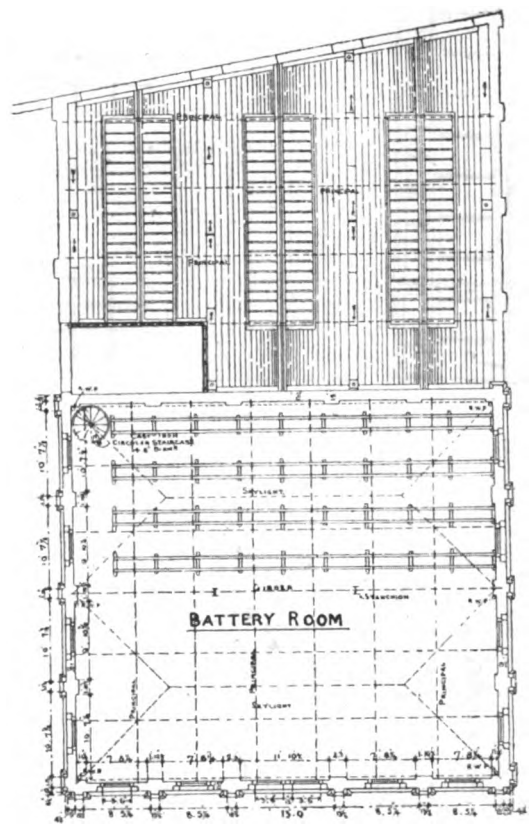
The arc lamp is by no means a stranger to the frequenters of Liverpool-street Station; indeed, the platforms have been lighted by electricity for some years with success and economy.

The enormous extensions that are in process of being carried out on the area of land between the old station and Bishopsgate street Without (practically amounting to an increase of the terminus capacity and space by 100 per cent.) has necessitated a complete remodelling of the electric lighting plant, with an even greater increase in its output; and a special building has been erected just outside the station to accommodate boilers, engines, and dynamos.

This new erection—as may be seen from the annexed illustrations — is of a very complete and extensive character—large enough, in fact, to suffice for a small town, the total capacity being not less than 1,200 h.p. in an area of 90ft. by 50ft. It stands fronting the main street, just at the point where the Great Eastern Company's main lines pass underneath the roadway at an angle near the junction of Norton Folgate and Shoreditch. It is built partly on a triangular plot of land at the ground-level, and partly on the railway arches themselves. The building is of red brick faced with stone, and presents a very handsome appearance from the roadway. The front of the engine-room abuts upon the pavement of Norton Folgate, and has massive entrance doors in the centre.



Ground Plan



First Floor Plan

G. E. R. Electric Light Installation—Buildings.

The steam-engines employed are eight in number—four of 200 i.h.p. each, and four also of half that capacity. They are of the inverted vertical compound type, coupled direct to dynamo generators of Crompton and Co.'s make. The engines are by Davey, Paxman, and Co., who also have provided the boilers—five in number—of which only four at present are erected. The boilers are of the Lancashire type, with mechanical stokers, and underground flues leading into the base of a large brick chimney stack just outside, 150ft. high.

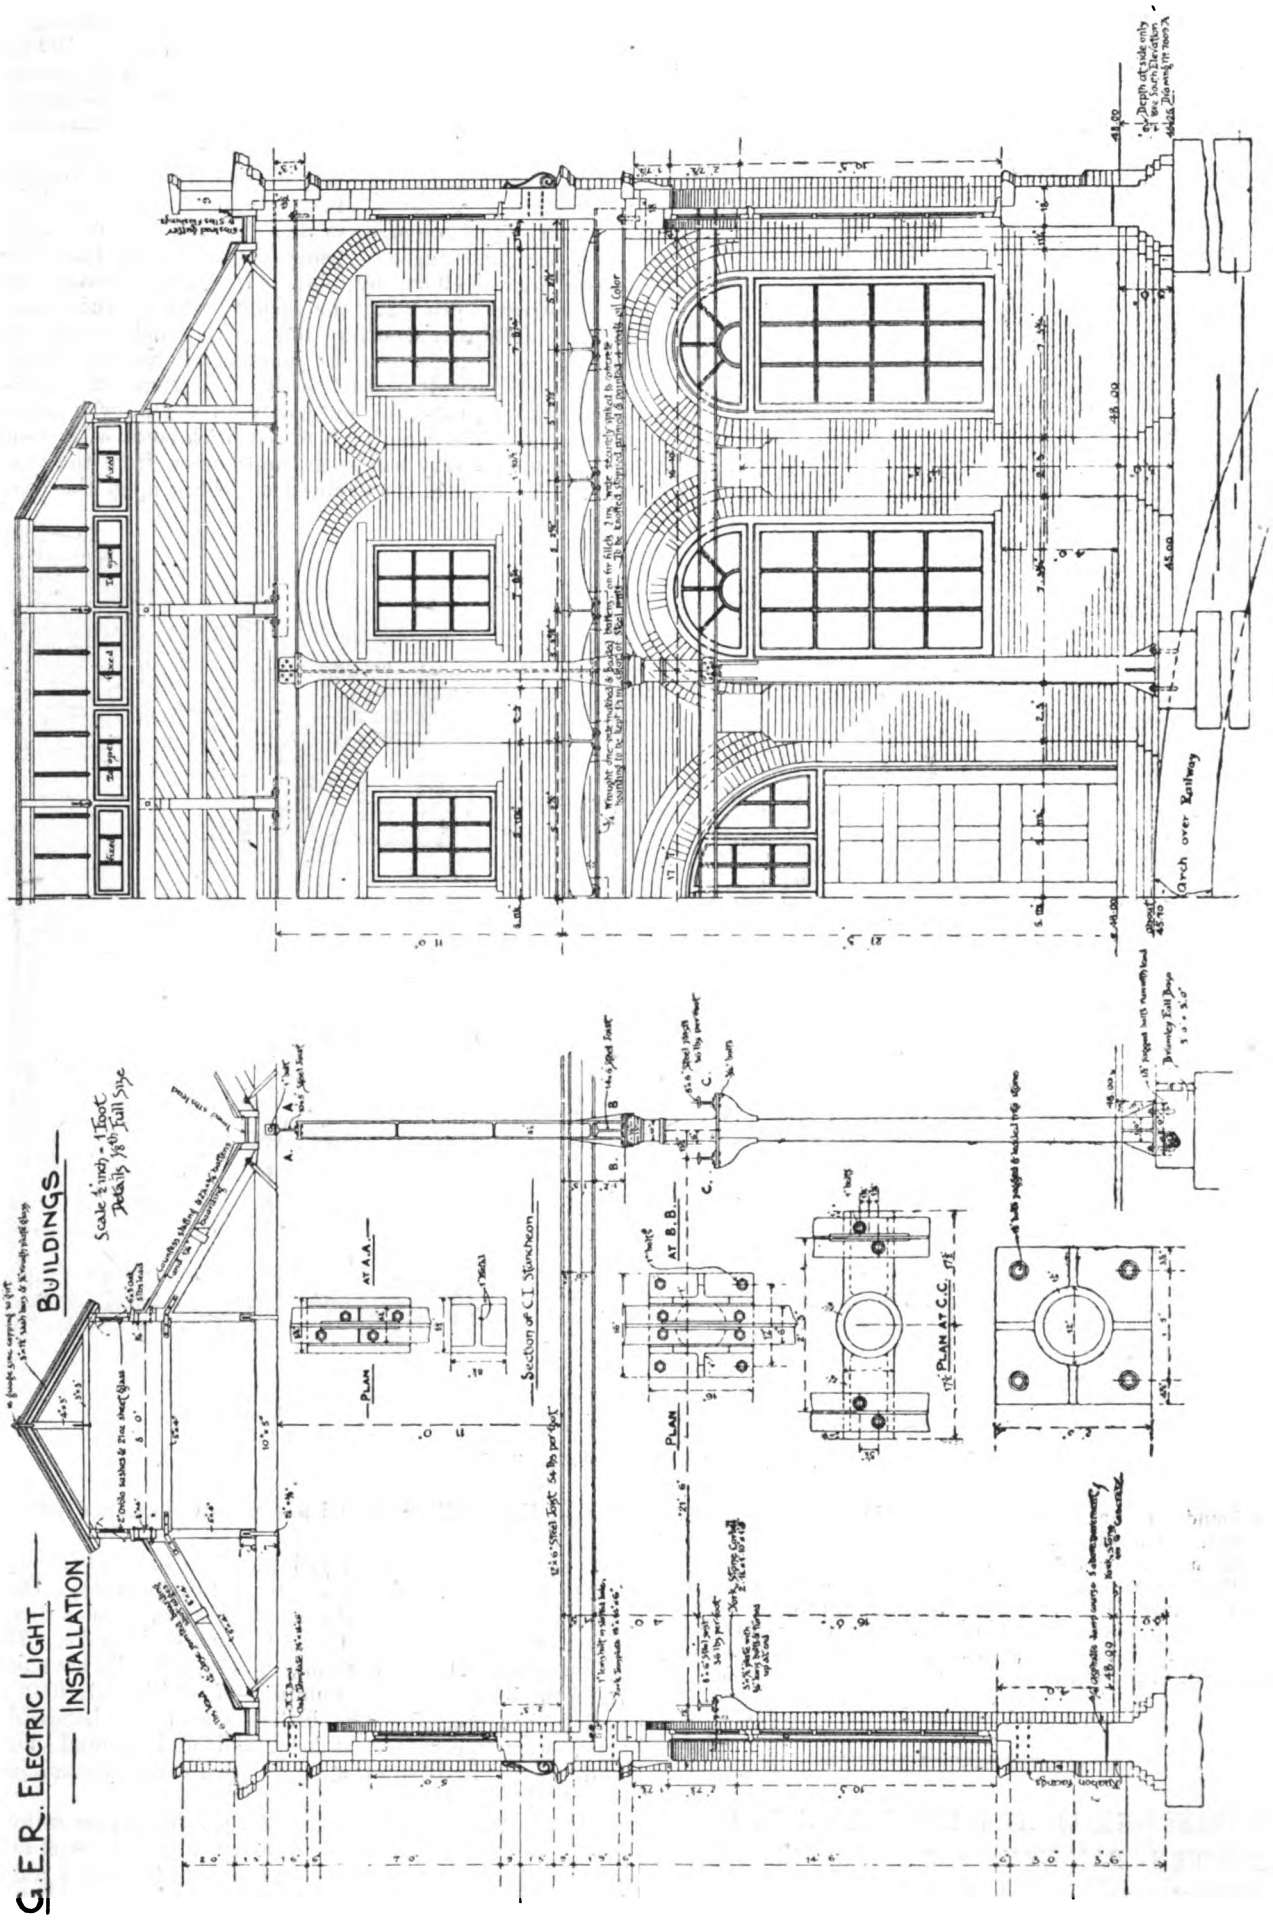
The engine-room has a height of 20ft. clear to the ceiling, and is provided in each of its two bays with light steel rails on a bracket gauntry way for an overhead travelling crane, by which the heavy parts of engines or dynamos are lifted as required.

On the first floor, above the engine-room, is a chamber of equal area intended for use as an accumulator-room, and approached from below by means of a circular iron staircase. The roof of this room, and also of the boiler-

Digitized by Google

house, is provided with adjustable louvre ventilators to allow the escape of smoke, heat, and fumes. As shown in the drawings, two cross-lattice girders, 3ft. 3in. deep, serve to sustain the boiler-house roof.

The current from the main switchboards—which occupy nearly all one side of the engine-room—is led along the railway lines to the station, where a large number of arc lamps light up the 17 platforms (involving nearly six miles of track), also the station halls and large areas. Then a great many incandescent lights are installed in the station



Digitized by Google

offices, in the Great Eastern Company's executive offices, the hotel close adjacent, and a number of shops and offices on the ground floor of the fine buildings with which the company has replaced the blocks of old houses formerly fronting on Bishopsgate-street.

The credit of design and elaboration of detail as regards the buildings for this supply station is largely due to Mr. J. Wilson, C.E., engineer to the Great Eastern Railway, to whose courtesy we are indebted for the illustrations that accompany this article.

FAULTS IN DYNAMOS.

(Continued from page 72.)

E. DISCONNECTION IN THE ARMATURE CIRCUIT.—Heavy sparking is produced on the commutator not only when the dynamo is running at its usual speed, but also when the speed is sensibly diminished, and this enables the fault to be distinguished from those previously described. As a rule, the fault occurs at some point where the wires of the armature are connected with the different segments of the commutator, and all these connections should therefore be tested, and the fault or faults repaired. If repairs cannot be effected at once, the defective segment may be joined to the next one to it, and the dynamo again started. When the disconnection is in one of the coils it should be unwound, the fault cut out, and the coil then rewound. If the dynamo is urgently required, connect the segment of the faulty coil with the next one to it. To ascertain whether disconnection exists in a coil, proceed as shown by Fig. 4.

F. SHORT-CIRCUIT IN THE ARMATURE OR COMMUTATOR. This is indicated when a brush, in passing over a bar of the commutator, gives out a spark which burns the metal. In addition, the dynamo will not give current. To see if the fault is due to metallic dust on the insulating material between the bars, each bar should be tested and cleaned. If short-circuit exists in the winding, the defective part must be found. As a rule, the short-circuited coil can be detected by its excessive heating. When the dynamo is set going to localise a short-circuit, great precautions must be taken, and the machine only run for one or two minutes at a time until the faulty coil is detected. Another method, longer, but more reliable, is to measure the resistance of each coil with a Wheatstone bridge, etc.

When short-circuit exists in a coil, the winding must be removed and the coil rewound after the fault is repaired. In case of necessity the coil can be cut out, the bars corre sponding to it connected, and dynamo restarted.

G. DEFECTIVE INSULATION OF THE FIELD COILS.—This fault is shown if the excitation is stronger in one of the field coils than in the other. One of the brushes will show more sparking than the other, and this sparking will be the same as in the case of bad adjustment. To find the fault, proceed as in "Bad Insulation of the Armature Coils."

H. WEAK MAGNETIC FIELD.—On approaching a small piece of iron to the pole-pieces, it will be seen that the magnetisation is feeble. Further, the point of least sparking will be continually altered by the disturbing action of the armature's magnetism, and the dynamo will not attain its normal voltage. The cause may be a break in the field circuit, or short-circuit in or bad insulation of the coils. If it is a break, proceed as in "Disconnection of the Field Coils." If a short-circuit in the field circuit, measure the resistance of each coil, as in "Short-circuit in the Armature Coils." Generally, the short-circuit is in one coil only, and one side of the magnetic field will therefore be weaker than the other. A small piece of iron placed exactly between them will show this by being unequally attracted.

Bad insulation of one of the coils will also create the fault. In this case one of the brushes will show more sparking than the other, and the procedure should be as in "Bad Insulation of the Armature Coils."

When the defect is accessible it is easily remedied, but when it is inside a coil the only course is to unwind, repair, and rewind.

III. ABNORMAL HEATING IN THE INTERNAL CIRCUIT.

Excessive heating of constituent parts of a dynamo may arise from various causes. In any case it is easy of recognition, because a touch of the hand from time to time will show it. So long as the temperature can be borne without pain there is no cause for alarm; otherwise—and more especially if there is smoke or a smell of burning—the dynamo should be at once stopped, and when the machine is quite cold the cause of derangement ascertained. In this way the heat will not have had time to pass by conduction to any extent beyond the defective part, which will be at the greatest heat. As a rule, no part of a working dynamo in proper order should have a temperature of more than 40deg. C. above that of the surrounding air. To take the temperature, the dynamo should be stopped and a thermometer covered with rag or cloth applied to its different parts. This does not give the dynamo time to cool, and, as the temperature of the machine-room is always known, it can be at once noted if anything is wrong. The first experiment is to localise the fault in one of the parts of the machine—armature, field magnets, or journals—while the various causes of the defect are as follows:

- A. Heating of the armature.
  - (*a*) Excessive current in the armature.
  - (*b*) Short-circuit in the winding of the armature.
  - (*c*) Foucault currents in the armature core.
  - (*d*) Humidity in the armature coils.
- B. Heating of the field-magnets.
  - (*a*) Excess of exciting current.
  - (*b*) Humidity in the field coils.
  - (*c*) Foucault currents in the pole-pieces.
- C. Heating of the journals.
  - (*a*) Defective lubrication.
  - (*b*) Metallic dust or foreign matter in the bearings.
  - (*c*) Bent, badly turned or finished shaft.
  - (*d*) Imperfect bearings.
  - (*e*) Drum or shaft making friction with the bearings.
  - (*f*) Belting too tight.
  - (*g*) Armature too near one of the pole-pieces.

A. HEATING OF THE ARMATURE.—Once abnormal heating has been found to exist, the source should be tested for:

(*a*) *Excess of Current in the Armature.*—When the fault proceeds from a surcharge from the dynamo, heavy sparking will be produced at the brushes.

(*b*) *Short-circuit in the Armature Winding.*—This fault is also characterised by heavy sparking. It should be tested for as in F.

(*c*) *Foucault Currents in the Armature Core.*—This is a fault of construction which will be perceived from the moment the dynamo is started. The engine driving it is severely taxed even before the dynamo gives current and no sparking is observable, which permits of the fault being distinguished from those previously described. A dynamo with this defect should not be taken over from the manufacturer.

(*d*) *Humidity in the Armature Coils.*—This fault or its effect is practically the same as short-circuit in the armature. To repair it the armature should be taken out and exposed to a moderate dry heat, or be subjected to a current equal to that ordinarily given by the dynamo. Under the action of heat or of this current the humidity will be gradually dispersed.

B HEATING OF THE FIELD MAGNETS.—Excessive heating of the field magnets is due to one of the three following causes:

(*a*) *Excess of Exciting Current.*—This fault is shown by an unusual heating of one or more of the field coils. When all the coils heat equally, the phenomenon is due to too strong an exciting current, and in that case extra resistance should be inserted. If, on the contrary, only one coil heats it is tolerably certain that the fault is due to a short-circuit in that coil, except the dynamo is series-wound, when it will be remembered the defective coil will heat less than that in good order. When the exciting current is too strong in a series-wound machine, it may be remedied by shunting or partly unwinding.

With a dynamo started for the first time the defect may arise from a considerable difference in the resistance of the coils, and it is a wise precaution, therefore, to test the coils for resistance before accepting the machine.

(*b*) *Humidity in the Field Coils.*—Dampness tends to decrease insulation, and the resistance of the magnetic circuit is weakened. In addition, steam is given off, and on being touched the coils will be found to be damp. When the dynamo is shunt-wound an ampere-meter will show an excess of current. In such case the coils should be dried, as indicated in "Humidity in the Armature Coils."

Digitized by Google

(*c*) *Foucault Currents in the Pole-pieces.*—This fault may proceed from defective construction or from a variable exciting current. When the dynamo is new, therefore, the cause should be at once ascertained. Put an ampere-meter in the field circuit and note the deflection. Variations of current can only be due to imperfect contacts. If they were absolutely bad the dynamo would not give current, and the procedure should be as in "Defective Contacts."

C. HEATING OF THE JOURNALS.—When the journals are abnormally heated, and the dynamo cannot be stopped, they may be cooled with water or ice, but this must only be resorted to in case of extremity. It is far better to stop the dynamo and test for the fault, which is ordinarily due to one of the following causes.

(*a*) *Defective Lubrication.*—See that the lubricators are full and not leaking or stopped up.

(*b*) *Metallic Dust and Foreign Matter in the Bearings.*—A close and careful examination should generally suffice, but it is advisable to lift the shaft and carefully clean it, as well as the journals and bearings.

(*c*) *Bent, Badly Turned or Finished Shaft.*—A bent shaft can be easily detected by turning it, when possible, with the hand. If bent, it must be replaced. If it is badly turned or finished, the fault may be remedied by means of a lathe or file.

(*d*) *Imperfect Bearings.*—If the shaft does not turn easily, but still does not exhibit any defect when the screws (which keep the bearings in position) are removed, the bearings may be too tight and require more play, and should be readjusted.

(*e*) *Drum or Shaft Making Friction with the Bearings.*—See if there is a fair amount of play (1·5mm. to 3mm.) between the drum or the shaft and the bearings. When there is not sufficient play, the drum must be shifted or the bearings filed down a little. When the shaft is faulty, it must be made smaller in the lathe or the bearings filed down.

(*f*) *Belting too Tight.*—This fault, as before remarked, may possibly result from a surcharge from the dynamo, or it may be due to tension of the belting. In the second case, the journal nearest the drum will heat more than the other.

(*g*) *Armature too near one of the Pole-pieces.*—This is a defect of construction, and will show itself when the machine is first started. If the armature is excentric it will be unduly attracted by one of the pole-pieces, and the journals will heat as when making friction with the bearings. It is possible to centre the armature by shifting the bearings, but it is a hazardous operation. The best course is not to accept the dynamo from the maker.

(*To be continued.*)

THEORY OF THE RESISTANCE OF A STRANDED CONDUCTOR.

BY W. H. EVERETT.

The resistance of a stranded conductor is necessarily a subject that does not admit of very accurate prediction; but it may be worth while to see exactly what the resistance depends upon, and we may then, from actual data in cable lists, find rough values for those quantities which cannot be determined by calculation.

We shall first proceed to investigate the total current which passes along a layer of wires wound helically round a circular cylinder of insulating material; the wires being supposed to be so wound that each wire is in contact with the two wires on either side of it, and the helices making an angle α with the direction of the axis.

Fig. 1 is a side view of a short length of one wire, which may be supposed developed; A B is the diameter of a cross-section, and A C is drawn making an angle α with A B, so as to be parallel to the end planes of the layer of wires, these planes being perpendicular to the axis, assumed straight.

Imagine for a moment that each wire is insulated from its neighbours. Except close to the ends, the equi-potential surfaces in the wire will be planes normal to the axis of the wire; for otherwise there would be a difference of potential between A and B, which would cause a cross-current between A and B, and this cannot exist, since there is no return path.

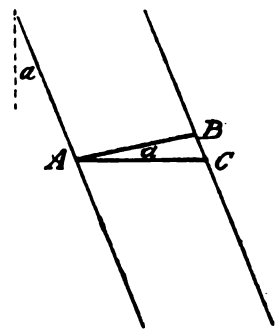

FIG. 1.

Thus the difference of potential between every pair of contiguous points in any two adjacent wirees will be

$$B C \times v,$$

where v = potential difference per unit length taken along a wire, or

$$2 a v . \tan \alpha,$$

putting $2a$ for the diameter of a wire.

Now imagine the supposed insulation to be removed from all the wires, and the above potential difference will act as an E.M.F., and send a current across from one wire to the next; in the direction A B, if the main current is flowing in the direction C B. The circuit is now completed from wire to wire in a helical path round the conductor. Suppose—

r_1 = resistance at contact between two adjacent wires per unit length;

r_2 = resistance across a wire, between its two surfaces in contact, per unit length.

Then the cross-current per unit length is

$$\frac{2 a v \tan \alpha}{r_1 + r_2}.$$

Hence the cross-current through any section, A C, of a wire, taken perpendicular to the axis of the helix, is

$$2 a \tan \alpha . \frac{2 a v \tan \alpha}{r_1 + r_2},$$

or,

$$\frac{4 a^2 v \tan^2 \alpha}{r_1 + r_2};$$

since it is the same as the current through B C. The direction of this cross-current is perpendicular to the axis of the wire.

The main current along a wire—that is, the current parallel to the axis of the wire—is

$$\frac{\pi a^2 v}{\rho},$$

ρ being the specific resistance of the metal.

The total current along any wire—that is, the total current across a section of it perpendicular to the axis of the helix—is therefore

$$v a^2 \left\{ \frac{\pi}{\rho} + \frac{4 \tan^2 \alpha}{r_1 + r_2} \right\}.$$

And if there are n wires in the conductor the total current through a normal section, and therefore through any other complete section of it, is

$$n v a^2 \left\{ \frac{\pi}{\rho} + \frac{4 \tan^2 \alpha}{r_1 + r_2} \right\}.$$

This result can be stated thus: Find the current that would exist if all the wires were insulated from one another, and increase this in the ratio

$$\left(1 + \frac{4}{\pi} . \frac{\rho}{r_1 + r_2} \tan^2 \alpha \right) \text{ to } 1$$

to find the whole current. Or we may say that the resistance is decreased in this ratio.

Digitized by Google

The equipotential surfaces in the layer will, in section, be a series of curves having points of inflection where they cross the axis of the wire, and also where they pass from one wire to another. They will be nearly straight in the neighbourhood of the axis of each wire, and will there be least inclined to a section normal to the axis of the wire. They will reach their greatest curvature near the contact surface between any two wires, and will have their maximum inclination in passing through the contact surface.

The precise shape of the curves depends, of course, on the nature of the contacts and the distortion in the adjoining parts of the wires. However, their form is shown sufficiently in Fig. 2, and will be seen to resemble that of waves in shallow water.

The effect of the cross-current on the resultant current is greatest at the parts in contact, the cross-current attaining there its maximum density.

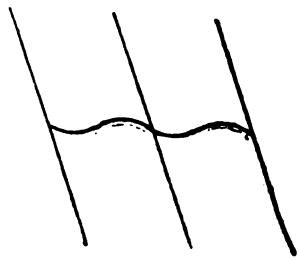

FIG. 2

We may now proceed from the consideration of a single layer to the case of a conductor formed of two or more such layers, the helices in any two contiguous layers being wound in opposite directions; in fact, the case of an ordinary cable.

If the region of contact between every two wires in contiguous layers were so small that it might be regarded as a mere point, then no current would pass between one layer and the next, since there would be equality of potential at every such point of contact.

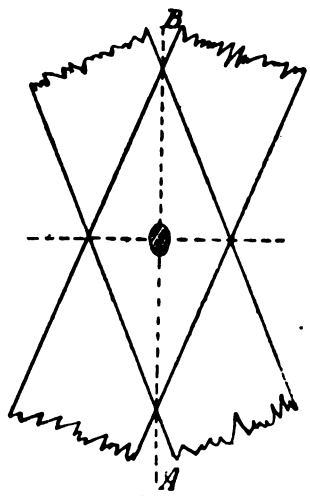

FIG. 3.

If the region of contact is not of negligible size, we may reasonably assume it to be symmetrically placed with regard to the two wires, so as to be divided equally by the bisectors of the angles between these two wires. By drawing equipotential lines for each wire, we see at once that there will be no difference of potential between the two wires at points on the longitudinal bisector, A B (Fig. 3); and on opposite sides of this line the differences, at corresponding points, will be equal and of opposite signs.

Hence there will be a resultant couple of potential differences, causing an eddy current round the longitudinal bisector; but there will be no resulting current from one wire to the other.

Therefore contact between contiguous layers does not increase the conductivity of a stranded conductor, but would tend, on the contrary, to decrease the conductivity. For the eddy currents would cause a waste of energy, E.M.F. being absorbed. This effect is probably almost, if not quite, negligible, owing to the small area of the contact surfaces. But it is noteworthy that the conductivity of a cable will, if anything, be increased by inserting a film of insulation between successive layers.

We may say, then, that each layer is independent of the others, and simply carries a current proportional to its conductivity as found above.

Accordingly, a stranded conductor acts really as a number of conductors in parallel—namely, the different layers. The current density and heating effect may therefore vary slightly in the different layers, depending in any layer on its helical slope and its resistance to cross-current.

We may subsequently examine a little more closely the expression found for the conductivity of any layer, and compare it with the results obtained in the case of actual cables.

(To be continued.)

ELECTRIC RAILWAY MOTORS: THEIR CONSTRUCTION AND OPERATION.*

BY NELSON W. PERRY.

(Concluded from page 86.)

I have often heard it claimed by horsemen, and have seen several instances myself where good results seemed to follow the plan, that to start a balky horse the best way is to simply jump out of the wagon and pretend to fix the horse's bridle, then get in, and on giving the signal, the horse which neither whips nor oaths could budge before would start right off as though nothing had happened. This was exactly what my friend seemed to have done and nothing more, and when, after we had all followed the injunction to get "aboard," he commenced to turn on the current, I could not but be astonished at the cheek, or, rather, the assurance which enabled him to keep up the appearance of entire confidence in the success of another attempt which he knew must fail for exactly the same reasons the other had. It is needless to state what the result was, further than to say that we did not get quite as far this time as we had before, and it is also needless for me to state how with equal composure he gave some excuse for going back again to the starting point. I think he said he had forgotten his monkey-wrench or something else.

I determined this time to speak, and when we stopped at the bottom I got off and commenced looking around as if hunting for something, and, stooping down some distance from the car so as to get him alone, cried out, "I've found it," and, as I expected, he rushed over, leaving the others behind, and I whispered, "Look at your positive brush on the front motor." He heard me and understood. He stooped down, though, as if to examine what I pretended to have found, and then, in tones loud enough to be heard by the others, said, "No, that's not it, but I've got something that will do as well," and lost no time in getting under the car and repairing the broken connection which had rendered useless one of our motors.

When we got on to the car again and he grasped the controlling switch I know I had more confidence that we could ascend the grade, but his appearance betrayed not one whit more than it had on the two previous attempts. As for the other parties, I am sure there was never a suspicion. We completed the return trip in great shape, and the trial trip was pronounced a success, and my friend was the hero of the hour. We returned to the car barns, and after he had seen everything safe for the night we walked home together. He seemed buried in deep thought for some distance, but finally broke the silence by, "You played me a darned mean trick." I was very much surprised at his attitude, thinking that he should rather have thanked me for helping him out of his difficulty. I knew that he would have found the difficulty after a while if left to his own resources, but thought I had saved him some embarrassment which further delay might have caused him, so I laughingly asked "How?" to which he replied, "By not letting me know before that you were an electrician."

The above anecdote is related merely to show how a little bravado judiciously used may save a reputation where

* From the *Street Railway Gazette*.

entire candour would be fatal. However reprehensible this practice may be in the abstract, it is one that pervades all walks in life, and is nowhere more prevalent, perhaps, than in the medical profession. It is, in fact, often used there to advantage, for if the physician should fail to inspire his patient with confidence in the beginning, it would be almost impossible for him to succeed later, and it is conceded that confidence in one's physician as well as in the remedies one takes is of the greatest help in curing disease.

If we find this practice so general in such an honourable profession as medicine, it is not surprising if we find it in the motorman, nor can we disparage it there while we uphold it elsewhere. In fact, I believe the motorman or electrical artisan is really less to blame than many others, by the circumstances of his position. Most often the electric motorman has obtained his position as a reward for faithful services as a driver or conductor of a horse car. In his previous occupation his hours have been long and his work exhausting both to mind and body, and when his day's work is done he is in no condition for study or more work. Besides, as a driver, he has probably mastered his business, and there has been no incentive to further study.

With this habit of mind he is transferred without any special preparation to the responsibilities of the care of the electrical equipment of his car. He is broken in by some one who has had a little more experience than he has had, and after having been shown the various parts of his apparatus and how they are intended to operate, is given a set of rules which tell him that he must do this and must not do that, and is allowed then to shift for himself. He is expected to talk about a current which he can't see and to guard against results which he knows only by name. A new language is placed in his mouth which he does not understand, but which he understands somehow is intimately connected with his business. His hours are no shorter than before, and books which would explain matters are too expensive, even if he had time to read them, or entirely inaccessible. His companion motormen are using this new language familiarly, and he soon acquires that habit almost unconsciously, and as soon as he is thus initiated into the charmed circle which speaks this foreign language, he becomes with his brother motormen a class distinct from that class from which they have all sprung. If he knows little of electricity, he still knows more than his former companions, and they treat him with a respect due to his superior knowledge. It will not do for him to admit ignorance, and he has an answer ready for every question. Nor does he care to show his ignorance among his companions by asking them questions or by asking questions of others in their presence, and in this way too often stands in his own light. That the average motorman is anxious to inform himself where he can do so under circumstances which are not embarrassing, I know well from personal experience, for I have had individuals ply me with questions when they could get me alone who would rather have died almost than to have asked the same questions in the presence of fellow-workmen.

No one blames them for this. It is human nature, and, as I have stated before, they have shining examples in the same practice in members of professions considered more dignified than theirs.

It was in the firm belief that the motorman would gladly inform himself, and therefore improve his position, if the opportunity were but offered, that the editors of the *Street Railway Gazette* have asked the writer to contribute a series of articles on electrical subjects which should gradually lead up to the street car motor and its management.

I feel sure that if the readers of the *Street Railway Gazette* will follow these articles conscientiously from week to week, they will be able to gain an intelligent knowledge of the theory of the electric motor which will often stand them in good stead and enable them to master situations not usually provided for in the rules and instructions with which they are furnished. With this added knowledge they will not only be more self-respecting, but be more respected, and as their usefulness is increased to their employer, so will their services to him become the more indispensable and preferment be more certain.

THE SCIENTIFIC USES OF LIQUID AIR.

A large and distinguished audience assembled at the Royal Institution on Friday evening to hear Prof. Dewar's lecture on "The Scientific Uses of Liquid Air."

To the majority of people, liquid air is only a scientific marvel; to a few it presents a collection of unsolved and most interesting problems, while at the Royal Institution it has become a valuable instrument of physical research. Produced in large quantities and stored by novel and ingenious methods, it is employed in the study of matter at 200deg. below zero, exactly as a spirit-lamp or a gas flame is used in studying the properties of different bodies at temperatures equally removed in the opposite direction from the normal. Prof. Dewar's lecture dealt in part with some properties of the liquid itself which have not previously been studied in equally favourable conditions, but was more particularly concerned with indicating the various important applications of a new and potent instrument of physical investigation.

Liquid air was shown in a condition which, though probably offering nothing novel to the eye of the untrained observer, is yet essentially different from anything hitherto shown on a lecture table. It has always been seen either in a state of active ebullition at ordinary pressure or of steady evaporation at the lower temperature produced by the action of an air-pump. On Friday night it was shown as a permanent fluid giving off no gas. Or, to put the matter another way, it has hitherto been shown imperfectly screened from the heat of surrounding bodies, while now it has been placed in such conditions that no extraneous heat could reach it. Formerly its temperature was kept down by its own evaporation, exactly as the temperature of boiling water is kept constant over the hottest fire. As exhibited by the lecturer its temperature was kept constant without loss of mass. This is effected by placing the liquid in a vacuum jacket, which is immersed in liquid oxygen contained in a second vacuum jacket and connected to an air-pump. Convection is annihilated by a vacuum which must be all but absolute, and conduction is shut out by the surrounding oxygen. No access of heat is possible except by radiation pure and simple, and this has already been proved to be, if not non-existent, at all events infinitesimally small. It is an interesting incident of the arrangement that common air can be shown in the solid condition. The importance of the complete isolation of the liquid lies in the fact that exact experiments can be made for the determination of its specific and latent heat. By lowering into the liquid a definite mass of platinum and measuring the gas evolved, it is easy to calculate the heat that becomes latent in converting the liquid into gas. Using similar methods to heat the liquid to a definite extent without altering its condition—*i.e.*, without converting it into gas—the specific heat can be calculated from the variation of pressure as registered by a column of mercury.

Taking a very highly exhausted bulb, containing only a little vapour of mercury at a pressure of a millionth of an atmosphere, and cooling it with liquid air until that minute portion of metal was frozen solid, the lecturer illustrated the part played in electrical discharges by ponderable matter. In a high vacuum at 200deg. below zero the difficulty of passing an electric spark in any form becomes almost insuperable. It would not be an extravagant inference from the phenomena were we to affirm that at 274deg below zero, when the rarest gas known to us would have suffered condensation, electrical discharge through the frozen void would become altogether impossible. But there are constant warnings in physical science of the danger of pushing inference beyond experiment, at all events in regions where we are approaching the extreme limit of our resources. By enormously increasing its voltage, the current may be made to pass even through the frozen-out mercury vacuum. But the discharge assumes a totally different form, the diffused phosphorescence giving place to luminous streaks. It would seem, therefore, that after a certain degree of rarefaction has been attained the gaseous molecules are no longer sufficient in number to act as carriers for an ordinary charge, while a more powerful one bridges the space only by the aid of the few that remain. The result almost justifies the presumption that ponderable matter is always necessary for the passage of electricity through space, but at the same time it opens up the question whether space can ever be wholly free of ponderable matter. If a certain amount of vapour be still given off by mercury at 140deg. below its freezing point, to what temperature below minus 274deg. must we suppose hydrogen to be cooled in order to ensure that no residuum shall remain in the gaseous form?

Prof. Dewar carried out a very simple but very striking experiment which forcibly demonstrates the truth of the molecular theory. He took a high-vacuum bulb containing only a minute quantity of mercurial vapour, to which was connected, by a short neck of from $\frac{1}{10}$in. to $\frac{1}{8}$in. bore, a smaller bulb containing liquid mercury. On applying liquid air to a portion of the larger bulb the contained vapour was at once condensed as a small mirror. On applying the liquid to a second portion of the glass no further condensation was obtained, thus proving that the metallic surface a couple of inches below could not supply vapour to replenish the larger bulb. But on inclining the apparatus so as to pass a globule of mercury into the larger bulb itself, the cold spots on the glass were instantaneously covered with dense metallic deposits. Of the myriads of molecules projected in all directions from the liquid mercury in the smaller bulb only a small percentage—which might be determined by the theory of probabilities—struck the orifice of the neck in such a way as to shoot clean through into the larger bulb. Hence the loss from condensation could not be made good, although there was free communication with another chamber containing vapour at a relatively high pressure.

The lecturer showed the method of determining the tensile strength of metals at 180deg. below zero. Large quantities of liquid air are necessary, since the considerable mass of metal forming the jaws of the testing machine has to be completely immersed. The results are extremely interesting. The breaking strain is in all cases greatly increased, and in some—*e.g.*, iron and German silver—is nearly doubled. In the case of certain metals equally remarkable increase occurs in the percentage of elongation before rupture, though the results on this point require verification. Thus, while chemical forces are in abeyance at very low temperatures, the physical force—which we call cohesion—asserts itself with immensely increased power. This is of great importance in connection with theories which have been ably advocated in some quarters, according to which a sufficient reduction of temperature would reduce the universe to "cosmic dust." That material, so valuable to some speculators, will have in future to be obtained from some other source than the disintegration of matter by cold. Lord Kelvin maintains, on the other hand, that cohesion may be accounted for without assuming any other force than that of gravitation, or any other law than the Newtonian. Contraction of bulk without reduction of mass is the sole condition he requires for indefinite increase of cohesive force, and this is obviously the condition supplied by Prof. Dewar's experiment, while the result is entirely concordant with Lord Kelvin's theory.

An American experimenter has found that a temperature of 80deg. below zero very greatly diminishes the power of a permanent magnet. Prof. Dewar has proved that this result follows only in the case of a super-saturated magnet. If a magnet be taken which has been passed through ordinary cycles of change, and therefore carries what may be called a normal charge of magnetism, its magnetic activity is markedly increased by reduction of temperature. This was shown by direct experiment, and the result was confirmed by coiling a wire round the magnet at ordinary temperature and immersing the end of the magnet in liquid air, when an electric current was instantly generated in the wire. An immense field of work lies before the physicist in connection with these experiments alike upon cohesion and upon magnetism. There are various theories which will have to take account as best they can of facts which cannot be questioned, however they may ultimately be explained. The increase of cohesion and magnetic force at very low temperatures must be taken in conjunction with the disappearance of electrical resistance in pure metals already worked out at the Royal Institution, and this, again, is complicated by the reverse effect obtained when the metals are contaminated by impurities of any kind.

Low temperature was shown to have a remarkable effect upon the colour of many bodies. For example, the brilliant scarlet of vermilion and mercuric iodide is reduced under the influence of intense cold to a pale orange, the original colour returning with the rise of the temperature. Blues, on the other hand, are unaffected by cold, and the effect is comparatively small upon organic colouring matters of all tints. This is of interest in connection with the efforts that have been made to find a chemical explanation of the colour of salts, and, indeed, with the phenomena of isormorphism in general.

COMPANIES' MEETINGS.

NATIONAL TELEPHONE COMPANY.

An extraordinary general meeting of this Company was held last week at the Cannon-street Hotel.

Mr. J. S. Forbes, who presided, stated that the directors felt that it would be to the interest of the Company if there were more frequent opportunities of meeting the shareholders. The Government had come to the conclusion that the intercommunication between the great centres for telephonic purposes must be taken over by them, and the Company and other licensees were to be charged with a limited service in certain areas. The State was to provide the communication in the nature of trunk wires in all the great centres, and the Company were to co-operate with the Post Office in carrying on with efficiency, and as economically as circumstances justified, telephonic communication, both local and through. This matter had now been pending a long time. There had been a change of Government since the Company entered into their agreement with the Post Office, and the agreement was in a state of suspense. Meanwhile, one of its conditions had been somewhat altered. When the Postmaster-General, duly authorised by the Government, put his initials to the heads of the agreement the directors assumed that that was the agreement; but there had been some discussion in Parliament on the subject, and the Government had pledged themselves not to complete the arrangement until it had been submitted to Parliament. During the last two months Parliament had been occupied upon matters even more vital to the community than the efficiency of the telephonic communication, and the result was that the agreement was not yet through. Their business was thus obstructed, and the general convenience was being neglected. The Company's year ended on April 30, but this was found to be very inconvenient, and they proposed that they should follow the custom of most of the great commercial companies, making up their accounts to June 30 and December 31—the two meetings which they suggested should be held in the year being arranged to fit in with those dates. Although they could not take any resolution on that occasion binding on the Company, they would like to have an expression of opinion which would justify them in taking such measures as would be legally requisite for making these changes. The accounts had been prepared for the half-year ended October 31, and they would be issued to the shareholders with the report of that day's proceedings. Complaints were still made against them, and he recently read that unless they went to Stockholm it was impossible to arrive at any clear comprehension as to how bad they were. His answer, however, was that Stockholm was not London. If they could get rid of the cost of wayleaves and of the Post Office royalty amounting to about 25 per cent. of the net income of the Company, and if they could also get rid of the awful difference which there was between 3s. 6d. a day for skilled labour in Germany as well as in many other parts of Europe, and 6s. or 7s. a day in England, they would be able to do their business cheaper. When they were accused in the *Times* with being the dearest and the worst thing of the kind in the world, he confessed that he was put out a little, and "the saddle ought to be put on the right horse." There was a delusion that their subscription in London was £20, but that was not the case. They had over 10,000 subscribers in London, and £15 was the average payment. He concluded by moving a resolution to the effect that two ordinary general meetings should be held in each year, and requesting the directors to take the necessary steps to have the articles of association of the Company altered accordingly.

Lord Balfour of Burleigh seconded the motion.

The **Chairman**, in answer to questions, said there was no doubt they must have a large reserve fund, but the time had not yet arrived when it need be determined whether the fund should be invested in securities apart from the business. At the present time it was in the business. The amount was £161,400. Their tenure was 18 years from the 1st inst., but the Government could resume possession before the end of that period. If the Government, under their powers, gave them notice in 1897, they would take possession on arbitration terms, but he did not believe that less than justice would be done by them in such a case. If their agreement with the Post Office were dealt with by the House of Commons in a manner detrimental to the Company, the latter would reserve their rights of re-entry.

The motion was adopted.

DIRECT UNITED STATES CABLE COMPANY.

The thirty-third ordinary general meeting of this Company was held at Winchester House on Tuesday, Sir John Pender, M.P., presiding.

In moving the adoption of the report, the **Chairman** pointed out that the revenue for the half-year ended December 31 last amounted to £41,051, as compared with £43,629 for the corresponding period of 1892, being a difference of £2,577 against the half-year under review, which was due to the severe commercial depression and the interruption in cable communication. The working and other expenses for the same period, including income tax, had amounted to £19,059, leaving a balance of £21,992 as the net profit, making, with the balance of £819 brought forward from the previous half-year, a total of £22,811. For the corresponding period of 1892 the working expenses and other payments amounted to £18,982. They had been able to pay interim dividends of 3s. 6d. per share for the quarter ended September 30, and of 3s. per share for the quarter ended December 31. These dividends amounted to £19,730, and they carried forward £3,080 on the revenue account. Although they had carried more traffic than in 1892, their receipts has been less. He hoped for better things in the future, though he expected that it would take some time before they returned to the old prosperous period. He thought, however, that he saw some sunshine. Complaint had been made of the reduction of the dividend from 3½ per cent. to 3 per cent.; but, considering that they had paid 5 per cent. for a long time, that they had a reserve fund of £101,000, and that they had paid off £21,000 in respect of cables and £100,000 in debentures, he thought the action of the directors was rather to be applauded than condemned.

Mr. E. M. Underdown, Q.C., seconded the resolution, which, after some discussion, was adopted.

COMPANIES' REPORTS.

CITY AND SOUTH LONDON RAILWAY COMPANY.

Directors: Charles Grey Mott, Esq., Harrow Weald Lodge, Stanmore, chairman; Charles Seymour Grenfell, Esq., Elibank, Taplow; Sampson Hanbury, Esq., Wyvenhoe Park, near Colchester; S. Barclay Heward, Esq., 96, Ashley-gardens, Westminster; Edwin Tate, Esq., 21, Mincing-lane, London, E.C.

Report of the directors for the half-year ending December 31, 1893, to be submitted to the half-yearly ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, E.C., on Thursday, February 1, 1894, at 12 o'clock noon.

The receipts from all sources for the past half-year have amounted to £22,821. 7s. 9d., and the cost of working has been £14,761. 11s. 3d., leaving a profit of £8,059. 16s. 6d. Inclusive of the balance brought forward from June 30 last, the net revenue account shows an aggregate total of £8,927. 10s. 7d. After making provision for the debenture and debenture stock interest, a balance remains available for dividend of £4,792. 8s. 10d. Out of this sum your directors recommend the full dividend of 5 per cent. per annum be paid on the preference shares, and that a dividend at the rate of ⅝ per cent. per annum be paid upon the consolidated ordinary stock, leaving a balance of £1,063. 13s. 10d. to be carried

Digitized by Google

forward to the next account. The following table shows the number of passengers, exclusive of season-ticket holders, carried since the opening of the railway in each half-year :

Half-year ended	Number of passengers.	Receipts (including season tickets. £ s. d.
December 31, 1890 (11 days)	165,000 ..	1,568 3 9
June 30, 1891.....	2,412,343 ...	19,403 6 9
December 31, 1891	2 749,055 ...	19,798 16 6
June 30, 1892	2,813,162 ...	20,931 4 2
December 31, 1892	3,117,602 ...	22,002 17 5
June 30, 1893.....	3,146,656 ...	22,458 6 9
December 31, 1893	3,093,351 ..	22,067 14 10
Total since the opening of the line	17,497,169 ...	£128,230 10 2

The traffic for the past half-year was prejudicially affected by the long continuance of exceptionally fine weather, and by the closing of Kennington Oval for the purpose of relaying the turf, so that no football matches have been played there this season. These causes, added to the general depression of trade, have caused a slight diminution in the number of passengers carried ; but, notwithstanding this, the general revenue receipts show a small increase over the corresponding period of last year, and the cost of working has been further reduced in spite of a considerable addition which has again been made to the local rates. The locomotives, rolling-stock, generating and other plant have been adequately maintained, and are in efficient working condition. The additional rolling-stock referred to in the last report is in course of delivery. The new sidings at the Stockwell Station are now in use, and prove a great convenience in working the traffic. The alterations at the King William-street Station are nearly completed. These will greatly enhance the comfort and convenience of passengers, and at the same time provide a ladies' waiting-room, and a room for left luggage and parcels, which will be a source of revenue to the Company. In the course of the half-year, £32,200 of the terminable 5 per cent. mortgage debenture bonds have been paid off, and are being reissued as 4 per cent. perpetual debenture stock. The Bill promoted by this Company for the extension to Islington and other purposes received the Royal assent on August 24 last. The parliamentary expenses incurred in connection with this Act were largely increased by it having been carried over from one session to another owing to the dissolution of Parliament, but having paid dividends in the meantime on the ordinary stock, the Company is now relieved from the obligation to provide the parliamentary deposit, whereby a very considerable saving will be effected. The directors retiring by rotation are Messrs. Sampson Hanbury and Spencer Barclay Heward, who are eligible for re-election. Mr. James Loriner Oliver is the retiring auditor, and is eligible for re-election.

REVENUE ACCOUNT, HALF-YEAR ENDING DEC. 31, 1893.

BUSINESS NOTES.

Margam.—Messrs. Drake and Gorham are to report on the electric lighting of this district.

Dublin.—The Town Council have received sanction to a loan of £24,400 for extending the electric light system.

Dover.—The Town Council have received from Mr. J. Matthews plans for the electric light station to be built at Ladywell.

Buxton.—The chairman of the Local Board has announced that a meeting regarding the Electric Lighting Acts would be held in month's time.

Debenture Issue.—The Chatham, Rochester, and District Electric Lighting Company is inviting subscriptions for its 5 per cent. first mortgage debentures.

Belfast.—The Electrical Committee of the Corporation have had under consideration Prof. Kennedy's report regarding the tenders received for electric lighting plant.

St. Pancras.—The Vestry have decided to lay an electric main from Tottenham Court-road along Grafton-street, and along each side of Fitzroy-square, at a cost of £495.

Electric Lighting in Aberdeen.—The electric light current will be passed through the mains in this city on February 19. The Lighting Committee have agreed to erect six additional lamps.

Woking.—The clerk to the Local Board mentioned at a meeting last week that no further tenders had been received for lighting. It was therefore decided to accept the tender of the electric lighting company.

Bradford.—The new Yorkshire Penny Bank has been equipped with an electric light installation by Mr. T. Harding Churton, of Leeds, and with electric bells and lightning conductor by Messrs. James Davis and Co., of Bradford.

Edinburgh.—The Lord Provost's Committee of Edinburgh Town Council have accepted an estimate for the removal of certain buildings at Dewar-place on the site of the proposed central electric lighting station at Torphichen-street.

Birmingham.—Twenty-three firms of architects have been invited by the Markets and Fairs Committee of the Town Council to send in competitive sketch plans for the new meat market and slaughter-houses, which are to be provided with an electric light installation.

Tender Accepted.—The tender of Messrs. Maxwell Bros. has been accepted for new mahogany fittings and electric lighting at St. Paul's Wharf, Upper Thames-street, E.C., for Messrs. Lever Bros. The amount for fittings was £103, and for electric lighting £75.

Llandrided Wells.—At the last meeting of the Local Board the clerk read a lengthy correspondence on the subject of electric lighting. It appeared that one company was willing to establish a temporary plant next season as an experiment. The question was again adjourned.

Tenders Required in Edinburgh.—Tenders are invited for an electric light installation in Chancelot Roller Flour Mills, Edinburgh. Specifications of the work required can be had by applying to the Secretary, Scottish Co-operative Wholesale Society, Limited, 119, Paisley-road, Glasgow.

Elmore's Foreign and Colonial Patent Copper Depositing Company, Limited.—Two petitions (one by Mr. J. Stevens, the other by Sir J. R. Meades) were down for hearing on Wednesday. It was stated, however, that the matters had been arranged, and the petitions were dismissed.

The Lighting Question at Chester.—An "open letter" to Dr. Hopkinson, consulting electrical engineer to the Corporation of Chester, has been sent by Mr. J. H. Wynne to a local paper. The writer criticised the proposal to combine electric light works and baths, and suggests that a new site should be obtained.

City and South London Railway.—The receipts of the Company for the week ending January 21 were £947, against £973 for the same period last year, or a decrease of £26. The total receipts for the first half-year of 1894 show a decrease of £91 compared with those for the corresponding period of 1893.

King's Norton.—The medical officer to the Rural Sanitary Authority, Dr. Hollingshead, has informed the Authority that the hospital was badly lighted, and he suggested that electricity should be substituted for the present system of oil illumination. It was resolved to defer the consideration of this question.

Portsmouth.—A Vestry meeting was held last week at St. Jude's Church, Southsea, to take into consideration the subject of laying on the electric light to supplant gas. An estimate furnished by electricians was that the cost of the alteration would be £300, but after a discussion the parishioners resolved to defer the matter.

Messrs. Drake and Gorham.—We understand that as the result of the lighting at Chatsworth, which has just been completed by Mr. Drake, he has been entrusted with the entire remodelling of the installation at 45, Belgrave-square by the Duchess of Montrose, who has lately been staying at Chatsworth. Over 300 lights are being arranged for.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 21st inst. amounted to £656. The directors have resolved to recommend payments of dividends at the rate of 5 per cent. per annum on the preference shares, and 1 per cent. per annum on the ordinary shares of this Company, less income tax, carrying forward £2,598.

Tenders Wanted for Leeds.—Tenders are now being obtained by the Yorkshire House-to-House Electricity Company, Limited, of Leeds, for an extension of the works. Two additional engines of

Digitized by Google

400 i.h.p. each are to be put down, together with corresponding electrical plant. Mr. R. Hammond is the consulting engineer, and the architects are Messrs. Milnes and France, of Bradford.

Tenders for Halifax.—Tenders are required by 1st February for the mason, joiner, ironfounder, slater, plumber, painter, and concrete work required for the erection of the electric lighting works in Foundry-street, Halifax, for the Electric Lighting Committee of the Halifax Corporation. Plans and specifications may be seen and forms of tender obtained on application to Mr. W. H. D. Horsfall, architect, 9, Harrison-road, Halifax.

Tenders Wanted for Blyth (Northumberland).—Tenders are invited by the 7th proximo for the lighting of the district for a term of 10 years, for the Cowpen District Local Board (Blyth, Northumberland). Plans of the district may be seen at the office of the Board, Commercial-buildings, Waterloo, Blyth, and particulars can be obtained from the Board's surveyor. Tenders to be sent to the clerk, Mr. Robt. T. Guthrie, Blyth.

Ayrton and Mather's Electrostatic Voltmeter.—Mr. Paul, of Hatton-garden, E.C., informs us that he supplied these instruments to the following electric lighting companies during the past year: The Metropolitan Electric Supply Company the City of London Electric Lighting Company, the London Electric Supply Corporation, the Brush Company, the Laing, Wharton, and Down Syndicate, besides the Bristol and Derby Corporations, and several foreign firms Mr. Paul has in hand some new patterns for lower readings.

Appointment of Receiver.—In the Chancery Division of the High Court of Justice last Friday, before Mr. Justice Chitty, Mr. Clapham, a holder of debentures in Latimer Clark, Muirhead, and Co., Limited, asked for a receiver and manager of the business and property of the company charged by the debentures. Mr. Kenyon Parker made the application, and Mr. C. E. E. Jenkins represented the defendants. Mr. Justice Chitty made the order asked for, appointing Mr. James Worley, with liberty to borrow up to £4,000 for the purpose of carrying on the business.

Cullingworth.—Since the Cullingworth Mills came into the possession of Messrs. J. J. Broadbent and Co, Limited, extensive additions and alterations have been made which have necessitated the provision of additional motive power, and Messrs. Marsden and Co., of Union Foundry, Heckmondwike, have recently completed the erection at Cullingworth of a pair of engines of modern type. Tate's electrical stop-motion has been applied, so that the engines may be stopped immediately from any part of the building in case of accident. The engine-house will shortly be fitted with electric light.

Issue of Debentures.—Messrs. Sperling and Co. have this week offered for subscription £100,000 5 per cent. debentures of £40 each of the Victoria Electric Railway and Lighting Company, Limited, at the rate of £98. 15s. per cent. These debentures are redeemable by 1932, by the application of a 1 per cent. sinking fund and annual drawings, for the first 10 years at £105 per cent, and thereafter at £100 per cent., and from a first mortage absolute on all the property, rights, etc., of the undertaking. The company has for 50 years the sole right to organise and work tramways, electric cars, etc., in the city of Victoria, British Columbia.

Bournemouth Electric Lighting License.—The Corporation of Bournemouth have applied to the Board of Trade for an electric lighting license for the purposes of lighting the pier, pleasure grounds, winter gardens, and other properties belonging to and under the control of the Corporation, a scheme for which has been prepared by Mr. F. W. Lacey, the borough engineer. The local electric supply company have written to the Board of Trade to the effect that they do not desire to oppose the application. The London and South-Western Railway Company have also withdrawn their opposition. The work therefore will now probably be carried out an early date.

Larne.—The clerk to the Town Council has read at a meeting of the latter an extract from a letter from Mr. Norris, the manager and liquidator of the electric light company, in which he stated that if the Commissioners press the matter of security, he thought that possibly some way could be found to meet the difficulty. The Commissioners might retain part of the payment until completion of the contract. It was decided that the clerk should write to Mr. Norris, asking if he would be agreeable to allow the £100 due by the Commissioners on April 1 next to lie in their hands as security for the performance of the contract for the lighting of the town for the ensuing three years.

Tenders Required for Yarmouth.—The Corporation invite tenders for the construction, supply, and laying down of the plant and mains for the supply of electricity in accordance with the specifications, general conditions, plans, and form of tender, which can be obtained at the office of Mr. J. W. Cockrill, A.R.I.B.A., borough surveyor, Municipal Buildings, Great Yarmouth. A deposit of £2. 2s. must be made with Mr. W. J. Nutman, borough accountant, Municipal Buildings, Great Yarmouth, for the specifications and plans, which deposit will be returned on the receipt of a *bonâ fide* tender. Sealed tenders, endorsed "Electricity," to be delivered at the office of the town clerk not later than February 19.

The Acton Hill Works.—On Saturday last the Acton Hill Electrical Engineering Works wore an unusually festive appearance, Captain Ronald Scott having arranged to give a tea and entertainment to 200 of the poor children of Acton in order to celebrate the recent marriage of his brother, Captain Percy Scott, R.N., with Miss Roma Dixon-Hartland, eldest daughter of Sir Dixon-Hartland, Bart., M.P. Captain Ronald Scott was ably assisted in dispensing his hospitality by Miss Walker and some lady teachers from All Saints' Church, South Acton, and the following members of his works: the Hon. Verney-Cave and Messrs. Garratt, Bircher, Squire, and Bouquet. The works were electrically lighted in a specially brilliant manner for the occasion.

Anglo-Amer'can Telegraph Company.—The directors, in their report, propose further dividends of 13s. 6d. per cent. on the ordinary stock, and of £1. 7s. per cent. on the preferred stock, making, with the previous payments, total distributions of £2. 11s. per cent and £5 2s. per cent. respectively for the past year, leaving £844 undivided. It is further stated that, "in view of the age of the Company's cables, and the necessity for assuring the efficiency of the service, the directors, after much and anxious deliberation, have decided to lay a new cable from Ireland to Newfoundland in the coming summer." A contract has been entered into with the Telegraph Construction and Maintenance Company for the manufacture and laying of 1,955 miles of cable between Valentia, Ireland, and Heart's Content, Newfoundland, for the sum of £450,000, which will be paid out of the renewal fund.

Eastern Telegraph Company, Limited.—The revenue for the six months ended September 30 amounted to £369,967, from which are deducted £98,106 for the ordinary expenses and £31,906 for expenditure relating to repairs and renewals of cables, etc. After providing £6,753 for tax, there remains £233,201, to which is added £1,133 brought forward, making a total available balance of £234,334 From this balance there have been paid—interest on debentures and debenture stock, £27,697; dividend on preference shares, £20,384; two interim dividends of 2s 6d. per share each on the ordinary shares. £100,000; totalling £148,081, and leaving £86,252, which is carried forward. Under the terms of a contract dated June 17, 1893, with the Portuguese Government, the Brazilian Submarine Telegraph Company and this Company have secured an additional 10 years of their respective privileges under existing Portuguese concessions. To obtain this extension, this Company and the Brazilian Submarine Telegraph Company undertook to connect Lisbon and this Company's general system with the Islands of the Azores, and the two companies hold a large proportion of the shares in the Europe and Azores Telegraph Company which has been formed to work the line. The new cable was laid in August last. A cable has also been laid from Zanzibar to Seychelles and Mauritius.

Cardiff.—Mr. R. H. Fletcher, the local representative of Mr. Massey, electrical engineer to the Cardiff Corporation, expects that the arc circuit will be completed and the streets of the centre of the town lighted by electricity by the end of March or the beginning of April next. In St. Mary-street lamps 22ft. high will be fixed in the middle of the road; but in Queen-street they will be placed alternately on either side of that thoroughfare. The reason for the latter arrangement is the existence of a double set of tram lines down the centre of the street, the moving of which, if practicable, would entail great expense. In St Mary-street the tram lines run, for the most part, along one side of the road only. Pipes for the cables are laid on the north side of Queen-street, on both sides of Castle-street, on the north side of Duke street, and down the east side of St. Mary-street. The idea is to first complete the arc circuit for the lighting of the streets, after which private applications for the electric light will be dealt with. At the central station on Canton Common the underground work is complete—the flues, etc., and the three boilers are being built in their settings. The whole of the foundations are ready to receive the engines, and the building is practically finished. A travelling crane is in position ready to put down the machines which will generate the electric current.

Edinburgh.—A memorial was presented at a meeting of the Town Council on Tuesday by proprietors, merchants, and inhabitants of the Lawnmarket asking that that thoroughfare should be included in the area to be lighted by the electric light. The memorialists pointed out that, owing to the height of the pavement above the roadway, a badly-lighted street like the Lawnmarket would be attended with danger to the public. Mr. Cameron supported the memorial, and Mr. Mackenzie said that four lamps would be required to light the Lawnmarket, and the committee had at least two still to dispose of. The memorial was remitted to the Cleaning and Lighting Committee, along with a notice of motion by Mr. Waterston to consider the electric lighting of the Canongate. Messrs. Mortimer and Auldjo Jamieson moved that it be remitted to the Cleaning and Lighting Committee to consider and report as to the advisableness of lighting George-street, St. Andrew square, and the cross streets from Princes-street to George-street with the electric light. The Lord Provost said the Council had recommended the lighting of only the main thoroughfares of the city with electricity, and if they once departed from that principle they would have councillors from one district fighting against those from other wards, and no one could say where it would end. Mr. Mackenzie said it would cost £1,000 to light George-street and St. Andrew's-square, and for streets where there was so little traffic at night, he did not think the expenditure would be justified. The motion was remitted to the committee. On the motion of Mr. Mackenzie, it was remitted to the Lord Provost's Committee to consider and report on the charges to be made for the supply of the electric light to citizens.

Northampton.—What is termed an electrical soirée was held on Tuesday and Wednesday in the Town Hall. The Mayor, at the opening of the soirée on Tuesday, expressed pleasure at being called upon to open that exhibition, which, so far as he knew, was the first electrical exhibition that had taken place in the town. He believed the promoters of the exhibition had in view the bringing before the notice of the public of Northampton some of the uses of electricity with which they

Digitized by Google

were not quite familiar. The speechmaking having ended, the company proceeded to witness the various experiments. The old Council-chamber was occupied by electrical appliances, including motors and cooking-stoves. Here Mr. H. J. Dowsing, M.I.E.E., of Messrs. Crompton and Co., explained how electricity can be used in three distinct ways in the household. First, he dealt with lighting, pointing out the absolute purity of the light and its safety, making several experiments to show how safe it really is. Next, Mr. Dowsing showed how the same electricity can be used as a motive power for carrying out the light operations such as cleaning knives and forks, grinding coffee, driving a washing-machine and a mangle. The production of heat was also explained, and in order to demonstrate how simple is the machinery by which electricity for lighting purposes can be generated exhibited a small dynamo, which could be driven by hand to light a small lamp. A small electric motor for driving a ventilating fan, and a coffee-grinding machine worked by electricity attracted much attention. Ladies were invited to have their hair curled by electricity by means of the curling iron heaters, and gentlemen were invited to have their hats ironed. Hot-plates for boiling, stewing, grilling, and carrying out all the operations required in the kitchen were on view, and Mrs. Dale, in the presence of a good audience, grilled some steaks, cooked tomatoes, and various kinds of fish and pastry, including Shrewsbury cakes and cocoanut buns. Mr. Dowsing repeated the lecture on cooking which he gave at the electric light works on Friday. By permission of the National Telephone Company, a telephone placing visitors in communication with Lincoln, Nottingham, Sheffield, Manchester, Leeds, Bradford, and the North of England, and London and the South was in operation. Those who so desired could listen to theatrical performances, the pantomime at the Leicester Opera House being heard very clearly.

Action about Incandescent Lamps.—At the Sheffield County Court last Friday, before his Honour Judge Ellison, the Sheffield Café Company brought an action against William Bakewell, electrical engineer, Shortridge-street, Attercliffe, to recover £10. The company originally claimed £9. 10s. for 76 lamps given up to the Edison and Swan Electric Light Company; £5. 5s. charges of Messrs. Ashurst, Morris, Crisp, and Co., solicitors to Messrs. Edison, Swan, and Co., and £3. 3s., charges of Messrs. Clegg and Sons, Sheffield. This made a total of £17. 18s., but the Café Company abandoned £7. 8s. of their claim and reduced it to £10. Mr. W. E. Clegg was for the plaintiffs, and Mr. A. Neal appeared for the defendant. According to the statement of Mr. Clegg, the defendant in June, 1892, showed the manager of the company a Zurich incandescent lamp. The cost of this was 2s. 4d., while the cost of the Edison and Swan lamp was 4s. Eventually it was agreed that the defendant should supply what lamps were required at 2s. 4d. each, and he supplied to the Company about 140 lamps. On the first of May, 1893, Messrs. Ashurst, Morris, Crisp, and Co., who were the solicitors to the Edison and Swan Electric Light Company, wrote to the plaintiffs, and stated that the Zurich lamps were an infringement of the patent of their clients. Eventually, rather than fight the Edison and Swan Company plaintiffs gave up 83 lamps, and paid the solicitors' costs, and they now sought to recover £10 from the defendant. Mr. Neal explained that the manager of the Café Company was shown two lamps—the Edison and Swan lamp and the Zurich lamp—and he chose the latter, no doubt, because it was cheaper. His Honour said that, according to decisions, he thought it must take it that an article which was an infringement of a patent was an injurious article. Mr. Neal: There is no evidence that it was an infringement of a patent. Mr. Clegg said if his friend raised that point he must have someone from the Edison and Swan Company to show that this Zurich lamp was an infringement of a patent. Mr. Neal replied that Mr. Whitehead, the manager to the Café Company, was shown the real Edison lamp and the Zurich lamp, and he chose the latter. Mr. Clegg said it was supposed that the defendant, as an electrical engineer, knew all about electrical patents, and would not offer an article for sale which was an infringement of an existing patent. After further argument his Honour decided to adjourn the case in order that he could look up the decisions on the points raised, and also to enable Mr. Clegg, if he thought fit, to call witnesses to prove that the lamps sold to the plaintiff company were an infringement of the patent of the Edison and Swan Electric Light Company.

PROVISIONAL PATENTS, 1894.

JANUARY 15.

854. **Electrical tramways.** Thomas Elcoate, Chestnut House, Norton, Stockton-on-Tees.

863. **Improvements in incandescent electric lampholders, ceiling roses, and other electric fittings.** William McGeoch, jun., Andrew Jackson McGeoch, and Frank Geere Howard, 108, Argyle-street, Glasgow.

908. **Improvements in apparatus for heating cylinders and parts of hydraulic machinery by the aid of electricity.** William Lawrence Williams, Walter Thomas Goolden, and Henry Willock Ravenshaw, 1, Queen Victoria-street, London.

916. **Improvements in electrical measuring instruments.** Haydn Thies Harrison, 46, Lincoln's-inn-fields, London.

JANUARY 16.

923. **Improvements in high and low tension electric fuses.** Benjamin Deakin, 2, Raeburn-street, The Avenue, Brixton, London.

993. **Improvements in brushes for dynamo-electric machines.** Pierre Joseph Charles Carron, 45, Southampton-buildings, Chancery-lane, London.

1003. **Improvements in electric railways.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Edward Hibberd Johnson and Robert Lundell, United States.) (Complete specification.)

JANUARY 18.

1087. **Improvements in methods of electric haulage.** Benjamin Howarth Thwaite and George Cawley, 95, Finsbury-pavement, London.

1110. **Improvements in automatic electric governors for prime or other motive-power engines.** Edward Joseph Bonner Lowdon, 41, Reform-street, Dundee.

1113. **Improvements in or in connection with dynamo-electric machinery.** Wilfrid L. Spence, The Elms, Seymour-grove, Manchester.

1115. **Improvements in safety devices for electrical circuits.** Albert Essinger and Thomas Harden, 55, Chancery-lane, London.

JANUARY 19.

1164. **Improvements in armatures of dynamos and electric motors.** Harry Penn and Loftus Lowndes, 25, Lordship-road, Stoke Newington, London.

1169. **Improvements in electric arc lamps.** George Hind Nisbett, 248, Stanstead-road, Forest Hill, London.

1199. **New or improved device for operating the buttons or switches of electric bells.** Henry George Farrell, Commercial-street, Sheffield.

JANUARY 20.

1268. **Apparatus for actuating electric switches, gas and water cocks, or the like.** Edwin James Howell, 45, Willow-road, Balsall Heath, Birmingham.

1306. **Improvements in electric heaters.** Edward O'Briern and the Electrical Installation Company, Limited, 53, Chancery-lane, London.

1307. **Improvements in electric switches.** Henry Hayes Cooper and the Electrical Installation Company, Limited, 53, Chancery-lane, London.

1308. **Improvements relating to electromagnetic railway brakes and to brake couplings for railway trains.** Henry Edmond Walter, 24, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1890.

873. **Electric supply motors.** Perry. (Second edition.)

1893.

1416. **Electric alarum.** Weygang.

1579. **Electric bells.** Weygang.

1812. **Electric switches.** Sansome and Hawes.

22311. **Storage batteries.** Usher.

22312. **Storage batteries.** Usher.

The Price of Shares.—"During the present month," says the *Financial Times*, "there has been a fair business doing in the shares of the electric lighting and supply companies. The subjoined table will show at a glance the movements which have taken place. It is expected that the reports, which in most cases are now about due, will show favourable results:

Stock.	Price January 2.	Price January 22.	Rise.
Brush	2⅜-⅝	2⅝-⅞	¼
City of London	11¼-½	11¼-½	—
St. James's and Pall Mall	5½-6	6-½	½
Ditto Preference	7½-8½	8-½	¼
Westminster Supply	5-½	5¼-½	¼
Metropolitan Supply	7⅜-8¼	8¼-⅜	½
Ditto Debentures	103-6	104-8	1½

NOTES.

Derby.—The Lighting Committee of the Town Council last week discussed the question of lighting the streets with arc lamps.

Churning by Electricity.—A "Disc" churn, operated by an electric motor, is now being shown at work at 54, Church-road, Hove.

Aluminium.—On Saturday, at a meeting of the Manchester Association of Engineers Mr. W. S. Sample read a paper on the manufacture of aluminium.

Lambeth.—The Vestry have decided to defer the re-election of the Electric Lighting Committee until after November next, the date of the elections to the district councils.

Station-Lighting.—The new goods station and buildings now being completed for the Great Northern Railway Company at Farringdon-street are to be lighted by electricity.

Lighting of Dredgers.—The large dredger now being built and engined by Messrs. Lobnitz and Co., of Renfrew, is to be lighted by electricity, and to be equipped with a search-light.

St. Pancras.—The Vestry have resolved to continue to pay to Prof. Robinson 4 per cent. on all distinctly electrical work carried out under his direction in connection with the King's-road station.

Southampton.—The council of the Hartley Institution have accepted an offer from Mr. W. H. Preece of scientific apparatus for the proposed engineering laboratory in connection with the institution.

New Book.—A new engineering compilation of 600 pages and with 700 illustrations, entitled "The Engineers' Year-Book," by Mr. H. R. Kempe, is about to be issued by Messrs. Crosby Lockwood and Son.

Telegraphy.—Mr. J. Henniker Heaton, in a letter to the *Times*, complains of the persistence of the postal authorities in the policy of levying the high rate of twopence per word on cablegrams to France.

Large Search-light.—"Wainhouse's Observatory," on the ridge of Skircoat, Halifax, is being equipped with an electric search-light of 25,000 c.p., whilst arc lamps are being placed on the ornamental pediment.

Tramcar Accident.—It is reported from San Francisco that a tramcar accident occurred there on Sunday. Whilst one of the electric tramcars was running it was overturned. Twenty-one persons were injured.

Proell's Expansion Apparatus.—Pamphlets setting forth the principle and advantages of Proëll's automatic expansion apparatus for steam-engines have been issued by Mr. H. Kühne, of 25-35, New Broad-street, E.C.

Telegraphy on the Congo.—It is stated that the Congo Free State has decided to construct a telegraph line from Boma to Lake Tanganyika. The line is to be completed in sections, the first portion running from Boma to Kenge.

Leeds Tramways.—The mayor has convened a meeting to consider the advisability or otherwise of the Corporation leasing the tramways to a company. The cost of haulage of the electric cars is said to be between 5½d. and 6d. per mile run.

Coventry Electric Cars.—The Warwickshire County Council recently decided, if the city of Coventry withdrew its opposition to the transfer of the tramway to the Coventry Electric Tramway Company, Limited, not to offer any opposition.

Rapid Transit.—A syndicate of railway capitalists, independent of the Wilson Syndicate, is said to be ready to undertake the construction of an underground rapid transit line in New York without the city's assistance.

The Institution.—A paper, entitled "Some Notes on the Electric Lighting of the City of London," by Major-General C. E. Webber, C.B., M.I.C.E., past-president, will be read at an ordinary general meeting to be held on Thursday next, the 8th inst.

Junior Engineering Society.—A paper on "The Construction and Working of Electromotors," by Mr. A. H. Dykes, A.I.E.E., will be read and discussed at a meeting of this society, to be held on Friday next, the 9th inst., at the Westminster Palace Hotel.

Conversazione.—The first annual conversazione of the Junior Engineering Society in connection with the Great Western Railway Mechanics' Institution at Swindon, and to which further reference is made in another column, was a most successful and interesting gathering.

Great Britain and the Antwerp Exhibition.—A meeting promoted by the London Chamber of Commerce, and presided over by the Lord Mayor, has passed a resolution welcoming the formation of a representative British section for the Antwerp International Exhibition.

Students of the Institution.—A students' meeting of the Institution of Electrical Engineers will be held at 28, Victoria-street, S.W., this (Friday) evening at 8 p.m. Experiments illustrative of the paper read at the last meeting on "Multiphase Currents and their Application," by Mr. C. S. Drysdale, will be made.

Newcastle.—The Town Council have referred to the Tramways Committee a communication from the Brush Electrical Engineering Company. The latter, in reference to statements that the Corporation were considering the question of changing the method of working the tramways, suggested the suitability of electric traction for the purpose.

The Proposed Cable Conference.—Sir Thomas M'Ilwraith arrived at Ottawa last week from the Pacific coast, and he expects to remain in Canada for some weeks before leaving for Japan. He learned that the proposed conference at Ottawa in reference to the proposed Pacific cable scheme had been postponed, but he is satisfied that arrangements will be effected for holding the conference of colonial representatives either in Canada or Australia.

An Advertising Novelty.—A novelty in the way of advertising is seen nightly on the New York streets. It consists of a handsome wagon, drawn by four horses, and brilliantly illuminated with electric lights. The edges of the wagon are outlined with lamps, and each horse is equipped with two lamps—one on the saddle and one on the top of his head. A storage battery is carried in the wagon, and the illumination is brilliant and attractive.

Lecture.—At the Midland Institute, a few days ago, Prof. Silvanus P. Thompson, F.R.S., lectured to a large audience upon "The Supply and Measurement of Electricity." In the course of his remarks the lecturer expressed the conviction that the time was not far distant when corporate bodies would have to become the purchasers of the temporary monopolies which they had allowed private companies to gain in the matter of electric supply.

The Government and Telephony.—It is reported that the agreement between the National Telephone Company and the Post Office has now been concluded, and that it will be laid on the table of the House of Commons when it reassembles. It is stated that Mr. Provand will meet with a good deal of support within the House if he moves for the appointment of a commission (to which reference

Digitized by Google

was made in a previous issue) to investigate the case for the municipalities, and also for the acquisition of the National Telephone Company's undertaking by the State.

Society of Arts.—On Monday, at 8 p.m., the third Cantor lecture on "The Detection and Measurement of Inflammable Gas and Vapour in the Air," by Prof. Frank Clowes, D.Sc., will be delivered. On Wednesday, at 8 p.m., a paper on "Automatic Balance of Reciprocating Machinery, and Prevention of Vibration," by Mr. W. Worby Beaumont, will be read. On Thursday, at 4.30 p.m., a paper will be presented on "Telegraphic Communication Between England and India: Its Present Condition and Future Development," by Mr. E. O. Walker, C.I.E., M.I.E.E., formerly of the Government of India Telegraph Department. The latter meeting will be held at the Imperial Institute, S.W.

End of the "Medical Battery" Company Prosecution.—At Marlborough-street Police Court, on Wednesday, the charges of conspiracy to defraud against Cornelius Bennett Harness, of the Medical Battery Company, Limited, James Montgomery McCully, and Charles Beavington Hollier were further heard. Mr. Avory, having called several other witnesses for the defence, Mr. Hannay, the magistrate, said he understood that Mr. Avory had other witnesses, but he did not intend to ask him to call them. He held that there was no probability of a jury convicting the defendants, and he should discharge them. The defendants were then discharged, a week being allowed the prosecution to say if they will take the responsibility of preferring an indictment at the sessions.

Forthcoming Visit of Edison.—Early in the coming spring Colonel Gouraud will have as his guest at Whitehall Court Thomas A. Edison, who is coming to take a rest in Europe this summer. Colonel Gouraud has devised what he calls a "vigintave kettledrum," at which the number of invited guests is limited to 20. These receptions will take place every Wednesday and Saturday afternoon. At the first "vigintave," a young American inventor, Mr. Burdick, of Chicago, exhibited his electro-pneumatic art brush, an instrument by which an artist is enable to produce the most delicate effects of stippling without actually touching the canvas. The paint is sprayed on to the canvas through a fine-pointed tube attached to a compressed-air bellows. Mr. Burdick gave an exhibition of his instrument at the Imperial Institute a few nights ago with considerable success.

The Antwerp Exhibition.—As noted elsewhere, the Electrical Trades Section of the Chamber of Commerce has decided not to advise or promote concerted action amongst the leading members of the industry as regards British exhibits in the approaching international show at Antwerp, leaving to individual enterprise the expenditure of time and trouble in sending goods over as may be thought advisable. So far as the developments of electricity are concerned, although there is to be a Galerie d'Electricité, no very exhaustive departments or classification seems at present to be attempted. In Section VI. of the schedule, Class 24, "Railway Plant," electric railways are included, and Section VIII. is confined to electricity, with the following sub-divisions: Class 28—Batteries, dynamos, transmission of electric force, lighting, production of the electric current, conductors, present knowledge of the subject, industrial application of electricity, transmission of the force, motors, traction engines, chemical electricity, different applications; Class 29—Telegraphs, telephones, and electric clocks, electric signalling, levels for ascertaining pressure of atmosphere, etc.

Chemical Potential of Metals.—Mr. W. D. Bancroft, in the columns of a German contemporary, treats of the chemical potential of metals. The author has investigated the difference of potential between the metals magnesium, zinc, cadmium, tin, lead, bismuth, mercury, and platinum in various salt solutions. He finds that when the pairs of metals are selected from magnesium, zinc, cadmium, tin, lead, and bismuth, neither the positive nor the negative iron of the salt solution has any effect on the E.M.F., which also remains constant although the dilution varies from 10 to 1,000 litres. When mercury forms one pole of the combination, the influence of the negative ion of the salt solution is very marked, but concentration does not influence the E.M.F. In the case of platinum, the difference of potential depends on the concentration of the salt solution when the dissolved salt is a haloïd. This is possibly due to the tendency of platinum to form platinochlorides, etc., in which the platinum is not present as an ion. It would appear, although the numerical agreement still leaves something to be desired, that the E.M.F. of the combination $M_1 \mid RX \mid M_2$ is identical with that of the reversible combination $M_1 \mid M_1X \mid M_2X \mid M_2$.

Action in Connection with the Niagara Falls Scheme.—An action has been brought against the Cataract Construction Company by Prof. Henry A. Rowland, of Baltimore, for £6,000, claimed as the value for services rendered in connection with the electric power transmission at Niagara. It appears that after the plans of the engineers of the Cataract Company had been formulated they were submitted to Prof. Rowland for his opinion as to their feasibility, and after a careful study he submitted, it is said, an opinion embodying improvements differing widely in character from the methods and designs indicated in the original plans. For this opinion Prof. Rowland presented a bill of £2,000 to the company, which was considered excessive and which was only honoured to the extent of £750. The action is a result of this. Prof. Rowland claims that practically all of his suggestions were adopted by the Cataract Company, and that by so doing they saved a large amount of money; and hence he considers his charges no greater than the magnitude and importance of the work warranted him in making them. Some eminent electrical engineers will appear on both sides, and it is believed that some interesting details relating to the Niagara project will be brought out during the trial.

Electromotive Forces of Insoluble and Complex Salts.—Dealing with this subject in the *Zeit. Physikal. Chem.*, Mr. K. Zengelis states that Ostwald obtained results for silver salts in agreement with the following general principles: Insoluble and complex salts, on account of the small concentration of their metallic ions, show considerable deviations from the calculated value of the E.M.F. of two-fluid combinations in which they occur, the deviation increasing with the decreasing solubility of the salt. Salts soluble in the complex compounds have a smaller deviation, and salts insoluble in them a greater deviation, than the complex compounds themselves. The author has tested the validity of these rules in the case of a number of slightly soluble and complex compounds of silver, copper, lead, nickel, and cobalt, and has obtained results in harmony with them. In the case of the phosphates of lead, cadmium, and silver, the E.M.F. gradually diminishes on standing, owing probably to the formation of basic salts. Similar diminutions were observed with the carbonates, and to a smaller extent with the arsenates. Where no basic salt is formed, as in the case of silver carbonate, the E.M.F. remains constant. With sulphides, an increase of the E.M.F. was sometimes noticed, probably due to the transformation of the hydrosulphides at first formed into normal sulphides.

Mechanical Traction in Liverpool.—Sir D. Radcliffe, chairman of the Liverpool United Tramways and Omnibus

Digitized by Google

Company, referred at a meeting of the latter on Saturday to some remarks of Mr. Munro about mechanical haulage. The chairman said that he hoped it might become the haulage system in Liverpool before long. Everything had been done to give mechanical haulage a fair trial. When Colonel Beaumont brought his system of haulage by compressed air, they gave him every facility for trying it. He said he would do it for 3d. per mile, and he (Sir David) ventured to suggest to him that probably 4½d. per mile would be the sum that the company would be glad to give. After a trial extending over some time it was a failure. The colonel wanted 5d. per mile, and then 6d. They subsequently had two or three trials of electric haulage, and this they found would cost 7d. per mile, and in addition the company would have been charged £1,680 for each engine and car. Seeing that the company had two or three hundred cars they would have to raise the sum of half a million of money to adopt the system. They did not shut their eyes to the fact that mechanical haulage would be much better for them if they could get it at something like a reasonable price. The company was a commercial concern, and it was no use their trying fads involving them in such expenses as had been indicated.

The Electrical Trades Section — London Chamber of Commerce.—On Monday last there was held at the Chamber of Commerce the meeting of this section that was adjourned from the previous week; the attendance, however, was still not very great. Regarding the three principal matters on the agenda paper, it was decided in the first place not to attempt any united action on the part of the section or industry with reference to the display of British goods at the Antwerp Exhibition to be opened in May next. Individual firms or interests who consider it worth while to incur the expense will, of course, meet with every possible assistance both from the section and from the Chamber of Commerce, but from a general point of view it was thought that hostile tariffs had so injured the continental market for British goods that the game would not be worth the candle. With reference to the second matter—the report of the Electric Traction Sub-Committee—the chairman (Mr. Garcke) had nothing more to say than we chronicled last week, except that probably all the interests involved would be asked to meet the Board of Trade in order to discuss the points at issue. The third item that was dealt with related to the formation of a permanent parliamentary committee; and with regard to this, it was decided not to attempt this at present, owing to the possibility of conflicting interests being involved.

Electromotive Forces of Polarisation.—M. Le Blanc, in the *Zeit. Physikal. Chem.*, gives a continuation of his investigations in this direction. From a further study of the E.M.F.'s of polarisation in salt solutions, the author finds that at the decomposition point in a solution from which a metal is deposited on the cathode, the E.M.F. of polarisation at this electrode is equal to the electrolytic solution pressure of the metal in the solution, and is independent of the nature of the electrode, provided it is not attacked. The numerous apparent exceptions to this simple rule are referred by him to the development of gases at the electrodes, in which case the E.M.F. necessary for their liberation depends in great measure on the nature and condition of the electrodes employed. By suitable arrangement of his apparatus, he was able to show that in many of these cases the solutions exhibited the normal behaviour, and that the electrolytic decomposition and formation of water (by means of a gas battery) is a reversible process. Salts of zinc, cobalt, nickel, and cadmium have a high decomposition point, and usually deposit the metal without evolution of hydrogen. This behaviour is due to special circumstances, and it is shown that under appropriate conditions hydrogen appears at the cathode, and not the metal. The assumption that the atoms of gases contain a greater amount of energy than the molecules is considered by the author to be untenable. They form two states of matter with practically the same energy content, the difference between them being that the atoms enter into chemical action with a great velocity of reaction, which is only approached by the molecules when a catalyst is present.

Explosions of Gas in Manholes.—In our last issue reference was made to the report prepared by Mr. W. H. Preece for the Commission of Sewers on the recent explosions in manholes belonging to the City of London Electric Lighting Company in Ludgate-hill and St. Paul's-churchyard. Mr. W. H. Preece states that the two explosions occurred simultaneously in a box in Creed-lane and in another nearly opposite the premises of Messrs. Howell in St. Paul's-churchyard, a distance of 55 yards apart. The effect of the explosion was to blow the covers of the boxes to a considerable height in the air. One of them broke in falling, while the other made a hole in the pavement and stood upright in the aperture it made. One person (a boy) was injured. A careful examination of the boxes revealed the fact that the explosions were caused by an accumulation of coal gas and air in the pipes and boxes. The cables carrying both the public and private current were in good condition, and the electrical tests proved that there was no leakage on the circuit to cause the accident. At the time of the explosions some of the company's men were working at a distance of 50 yards away, and they were using a red-hot plug or "rat." It was possible, Mr. Preece says, that this red-hot iron might have ignited the gaseous mixture by passing upwards into the boxes referred to. If it were not for leaky gas-pipes no accumulation of gas could take place; but the mains are, he says, notoriously leaky. The City of London Electric Lighting Company, as mentioned last week, has since introduced a system of inspection of boxes, and by extra vigilance on the part of the employés it is hoped that an immunity will be secured from such explosions in future.

The Prize for an Improved Electric Traction System.—"If the enquiries we receive are a criterion of the interest taken by electrical inventors in the contest for the £10,000 prize offered by the Metropolitan Traction Company of New York for a system of street railway traction as economical as the trolley," the *Electrical World* says "that company will be most abundantly supplied with projects. While thus inventors are presumably responding with alacrity to the demand made upon them, an obligation rests with the company to meet them in a similarly liberal spirit, or at least to give assurance that their labour will receive the consideration that it deserves. If, however, the date first given, March 1, before which a working exhibit must be placed in operation, is adhered to, there is no chance, except under extraordinarily favourable circumstances, for any competition under the terms given. We learn that the Waddell-Entz Company has formally entered the competition with its storage-battery system, which has been working so efficiently on the Second-avenue line, but this required no preparation on its part on account of having a practical plant already in operation. We also learn that a system based upon contacts made by means of magnets is preparing to compete, but this also was in experimental shape before the prize was offered. Unless the time of competition is considerably extended these two may be the only systems in shape to compete, and thus no benefit will be derived from impetus given to invention by the offer of the prize. While we believe any suspicion as to ulterior motives on the part

Digitized by Google

of those who offered the prize would be most unjust, yet the discussion over the alleged manner in which the Niagara Construction Company benefited from information obtained in a similar manner would tend to give colour to charges by a disappointed inventor based upon the same grounds, if the competition were brought to a close before an opportunity for trial were afforded. We trust that the Metropolitan Traction Company will see the impossibility of accomplishing its purpose within the time limit given, and offer an extension sufficient to enable any inventor who can enlist the necessary support to put his system to a practical test. By so doing it will not only derive the benefit desired, but perform a public service of no mean proportions."

Electricity and Plant Growth.—Dr. G. J. Romanes has given the results of a long series of experiments on mustard seedlings exposed to constant electric light and to interrupted flashes respectively. The plants were grown in the dark till they reached a height of 2in., and a thick plate of glass was placed between them and the electrical apparatus. At a temperature of 70deg. F., and in a dark moist camera with a shutter (which by being opened exposes the plants to the light), vigorously growing seedlings began to bend to the electric sparks 10 minutes after exposure, and bent through 45deg. in as many minutes. In an hour and a half the leaves were bent horizontally to the light. There is a more rapid rate of bending than can be produced on the same pot of seedlings when the side formerly protected is uncovered and exposed for a similar duration of time, either to constant sunlight or to constant diffused daylight. This is the case even if the sparks (or flashes) succeed one another at intervals of only two seconds. Thus the heliotropic influence of electric sparks (or flashes) is greater than can be produced by any other light. Dr. Romanes then exposed one pot of seedlings in a camera to the constant light of a Swan burner, and another pot of similar plants in a second camera, placed at the same distance from the same source of light, but provided with a flash shutter working at the rate of two seconds intervals. The rapidity with which the bending commenced, and the extent to which it proceeded in a given time after commencement, were found to be considerably greater in the seedlings exposed to the flashing light than to the constant light. In his next set of experiments he found that the bending of the seedlings occurred within 15 to 30 minutes, if bright sparks were supplied at the rate of only one per minute. It is strange, however, that these remarkable results are not accompanied by the formation of any particle of chlorophyl. He has used thousands of plants in his work, yet he has never seen the slightest shade of green tinging the etiolated seedlings which had bent towards flashing light. On one occasion he kept a stream of a hundred sparks per second illuminating some mustard seedlings continuously for 48 hours; and, although this experiment was made for the express purpose of ascertaining whether any chlorophyl would be formed under the most suitable conditions by means of flashing light, no change of colour in any of the seedlings was produced.

Lighting of Halifax.—The Municipality, who are laying down plant for the supply of the electric light, only obtained in October the sanction of the Local Government Board to borrow the £30,000 needed for providing the station, but a site for the central station has been acquired, the excavations for the cables have been commenced, and the plant has been ordered. Mr. Wilmshurst, the electrical engineer to the Corporation, decided upon the high-pressure alternating-current system. At first the Corporation contemplated utilising for the purposes of the central station the Salvation Army Barracks, which they own; but, owing to its distance from railway and stream, this site was abandoned for the Park Mills site in Foundry-street, on the right bank of the Hebble brook, from which water for condensing purposes can be obtained, and close to the railway, from which it is proposed to run trucks into the top of the boiler-house and shoot the coal direct. The area of these conveniently-situated premises is about 5,000 square yards, and upon the site are to be erected boiler and engine houses, which it is proposed to fit up at present with three boilers, four engines, and two alternating-current dynamos. The works, however, will be so constructed as to be capable of accommodating additional plant when extensions are necessary. The plant will consist of three Lancashire boilers, 30ft. by 7ft. 6in., pressure 140lb. per square inch. fitted with mechanical stokers, to be supplied by Messrs. Yates and Thompson; one Green's economiser; two compound horizontal condensing engines of 200 i.h.p. each, one of 100 h.p., by Messrs. Pollett and Wiggell; two compound horizontal non-condensing engines of 20 h.p. each, by Messrs. Robey; two alternating-current dynamos of 100 units each, giving 50 amperes at 2,000 volts, one of 50 units, by the Electric Construction Company; two exciters capable of exciting three alternators and a complete switchboard, by Messrs. Fowler. Indiarubber cables, supplied by Messrs. Siemens, are to be drawn through pipes. At convenient points sub-stations will be constructed, in which transformers, made by Messrs. Parsons, are to be placed. The current is to be generated at 2,000 volts, and carried by high-pressure mains to the centre of the town. There the current will be transformed by means of transformers before entering the houses. Some 12 miles of streets are to be opened at once, and 35,000 yards of cable laid underground. The work is to be rapidly pushed forward, with the view to the works being opened in June or July next. The supply of current will be charged by meter.

After-Glow in Exhausted Bulbs.—An article on this subject by Messrs. H. M. Martin and W. H. Palmer, jun., appears in the *Electrical World*. The authors state that having failed to note in any communication on the subject of the phosphorescence of exhausted bulbs in a field of high potential and frequency any mention of what, for want of a better name, may be called the "after-glow," they are led to believe that a brief description of this phenomenon may be of general interest. If an exhausted bulb, having a sealed-in electrode, be held in the hand and approached to a terminal of an induction coil giving moderately high potential and frequency, the whole interior of the bulb will be permeated by a phosphorescent glow; if, now, the bulb be slowly withdrawn from the field of excitation, the degree of luminosity will gradually diminish till a point is reached beyond which the intensity of the glow, now greatly attenuated, is practically unaffected by any further increase in distance from the terminal. It is this glow, entirely independent for its perpetuation of the field in which the bulb was charged, and continuing, they believe, until electrical equilibrium has been established between the rarefied gas and the electrode of the bulb, that we have called the "after-glow." That it is thus independent of the field of excitation may be proved by shutting off, after the "after-glow" has been established, the exciting current of the induction coil, when the glow will be entirely unaffected and continue, practically, for the same length of time as when the coil is in action. When the glow has become almost imperceptible it may often be stimulated into renewed life by shifting the position of the fingers on the surface of the bulb. After this has been done, and the glow has again died away, a single bright flash may be obtained by touching with one finger the projecting end of the sealed-in electrode. That the hand of the experimenter is a factor

Digitized by Google

in these effects may be shown by laying the glowing bulb on a table; the glow, though not extinguished, becomes very faint, especially if no object of capacity be near. The bright flash may still be obtained by again picking up the bulb and discharging as explained. They have repeatedly charged a bulb, shut off the primary current from the coil, carried the bulb to a remote part of the house, laid it on a table, and, after picking it up again, obtained a flash on discharging that could be seen some yards away. Lack of apparatus has prevented them from following up these experiments, which are now some months old, but they are valuable, at least, as additional and ocular proof of the electrostatic origin of the "Tesla bulb effects."

Train-Lighting.—Lieutenant Isaac N. Lewis, U.S.A., has succeeded in developing a system of car-lighting which is claimed to possess all the elements of a successful commercial apparatus. The system, which has been tested on a car of the New York Central Railroad, consists essentially of a dynamo driven from the car axle, supplying current to a set of storage cells which furnish current during the period of stopping of the train, and during other periods, as will be explained presently. The dynamo is mounted on the truck, and consists of a four-pole iron-clad machine completely enclosed so as to exclude all dust, and provided with graphite bearing for the armature shaft. The armature is driven directly from the axle by means of spiral spring flexible "belting," which is capable of responding to all the movements of the truck, and thus obviates all necessity for equalising arrangements—such as belt tighteners, idlers, etc., to keep the belt taut. The dynamo, of one kilowatt capacity, weighs barely 2,000lb. and readily finds room on the truck. The current is led into a battery of 11 cells, and these feed the 20-volt lamps, of which there are 12 to each car. The *Electrical Engineer* of New York states that, being driven directly from the car axle, some means must, of course, be provided first for maintaining the direction of the current supplied to the batteries uniform, and at the same time cutting out the dynamo when its speed falls so low as to bring its E.M.F. below that of the storage batteries on the car. Again, the arrangement must be such that the dynamo potential remains practically constant, no matter at what speed the car is running. All these necessary requirements have been worked out with great simplicity by Lieutenant Lewis. A uniform direction of the current is maintained by a pole-changer, while the cut-out, operated by a governor on the dynamo shaft, interrupts the current when the speed of the car falls below that required for the charging of the cells. The uniformity of potential at varying speeds is controlled entirely by a particular and simple method of winding of the dynamo, and no auxiliary regulating apparatus of any kind is employed. Throughout a range of current from 0 to 35 amperes, for which the dynamo is designed, the E.M.F. does not differ one volt, at all the varying speeds, from the point at which the dynamo is cut in up to the maximum. The cutting out of the current from the dynamo below a certain speed relieves the locomotive of all work, when the battery is not charging; as a consequence, also, the dynamo does not act as a drag on the locomotive when starting. The means by which all these operations are performed are exceedingly simple. Besides the car fitted up on the New York Central Railroad, a number of cars on other roads will shortly be equipped, so that the system will soon have a crucial test.

Faulty Wiring of Vessels.—The *Pall Mall Gazette* of Tuesday contained an article entitled "A Needless Ocean Danger," dealing with defective wiring of steamers. Reference was first made to two or three fires on board ship attributed to faulty methods of wiring, and it was pointed out that the ordinary precautions enforced on land are not compulsory at sea, and that inferior work is nearly certain to result sooner or later in an outbreak of fire. Continuing, our contemporary says: "It would be breaking butterflies with steam-hammers to elaborate the importance of sound installations—on land. How much more essential, then, is the soundness of installations employed at sea, where a conflagration is so much more terrible an affair? It might well be expected, then, that specifications for the lighting of ships would in all cases be drawn up by experts. But that is not the case at all. The contractors have practically *carte blanche*, and, as keen competition prevails, the result is the use of shoddy material, improper casing, and indiscriminate fixing. To give instances first of the last-mentioned abuse, conductors are frequently led through cargo holds, where they are inaccessible. They are also led sometimes through coal-bunkers, where explosive coal gas accumulates; while in some cases the safety fuses have been fixed in the bunkers. These safety fuses have porcelain covers, certainly, but a lump of coal would obviously smash such a cover easily. Obviously, when led through such places the conductors should be enclosed in strong metal tubes. If indifferently insulated, they are liable to suffer rapidly from the heat and dampness arising from the cargo and the frequent wetting. Inferior insulations under such circumstances are bound either to melt or to rot away, and the wires thus exposed may corrode through, snap asunder, and cause a fire. Indeed, it is pretty well known among maritime people that small fires are frequent on board electrically-lighted ships. Nobody desires to quarrel with the use of the electric light aboard ships. It is the safest of all illuminants where the installation has been thoroughly well put up. It is a deadly risk when the installation has been badly put up. Surely, then, there should be some expert supervision over all electric light fittings; while at least one engineer and one deck officer of every ship's crew should of necessity be certified as possessing theoretical and practical knowledge of electricity and the dangers involved in its unprotected use. So far as we have been able to learn there has never been any attempt made to secure such special fitness among officers and engineers. In many instances the fitting of electric light installations is put up for competition, the lowest tender securing the contract. The difference between good and bad work means perhaps a divergence of 30 or 40 per cent. in the cost; and the electrical engineer who fits up the installation only has to take care to secure that his work stands the six hours' test which is guaranteed. With this tendering incentive to put in cheap and nasty work, and without any special electrical knowledge being required of any officer or engineer aboard, is it much to be wondered at that the installations are frequently bad? The Board of Trade issues no regulations on the subject, and Lloyd's Registry sends out nothing but a series of 'suggestions.' These 'suggestions' are certainly admirable, but there is no compulsion behind them to enforce them." Our contemporary has before it, "taken from British steamers marked 100 A in Lloyd's Registry (the highest class at Lloyd's, that is), cables which are far from fulfilling those conditions. The Board of Trade have been asked to place in their yearly casualties return a column for electric lighting accidents. Their answer was that the request would receive attention when the next classification of casualties was made, but that hitherto very few accidents had been attributed to the cause mentioned. This suggests," our contemporary concludes, "that the Board of Trade are waiting for the 'Campania' to be burned, with an admiral and a bishop aboard, before they move in the matter."

THE BOARD OF TRADE AND ELECTRIC TRACTION.

In our issue of November 24 last year we gave the draft regulations issued by the Board of Trade, which regulations, when settled, will control electric traction in this country. We did not hesitate to pronounce some of the draft regulations as unnecessarily stringent, and suggested concerted action among those interested. Action of a kind has been taken, but not so concerted as we could wish it. The London Chamber of Commerce, the Tramways Institute, and the Association of Municipal Corporations have been giving careful attention to the subject, and we understand the latter body has obtained a report on the regulations from Prof. Fleming, who is retained as adviser. Negotiations are proceeding with the Board of Trade, and we understand that at an interview with this authority the view was expressed that in particular cases the regulations might be modified. Prof. Fleming, in his report, after referring to the general views of the opinions given in the parliamentary joint report, points out that the draft regulations are rather calculated to take away what the committee would give than otherwise. He says: "They are in effect so stringent in the limits which they put upon stray or leakage currents that they do in effect, as they stand, render it quite unnecessary for the telephone companies to duplicate their wires, because they throw the whole burden of avoiding the evil upon the tramway companies or owners. The point at issue between the telephone companies and electric tramway companies is really about the right to use the earth as a return. The Joint Committee say in effect: We recommend that neither of you use the earth as a return, but that the tramways shall provide conductivity enough on their uninsulated metallic return to take up all their own current, and the telephone companies shall provide insulation enough by a complete metallic return to prevent any taking up of leakage currents which may exist. The question then is, Have the Board of Trade in their draft regulations laid the burden wholly or too heavily upon the tramway companies or owners, and thereby lightened the burden laid upon the telephone companies? My own impression is, after carefully studying the draft regulations in the light of experience, and in that of the evidence laid before me, that the Board of Trade have set up a standard of perfection for the electric tramway companies which can never be reached in practice, or which can only be reached by an expenditure which will make the enterprise unproductive."

An examination of the regulations clause by clause is given, but at the present moment we cannot give all the criticisms. Suffice it to say that little is discussed as regards paragraphs 1 to 4, but on paragraph 5 the report discusses earth resistance as follows: "The question of what earth resistance is really dependent to a large extent upon what current is to be sent through this earth resistance. If any considerable current, such as 10 amperes, may pass up through these earth connections, then, unless they are very much larger than it would be generally possible to obtain, I doubt whether a terminal earth resistance as low as one ohm is possible. I cannot see the reason for the necessity of this supplementary earth resistance. It is assumed that the conductor in connection with the negative terminal of the generator is an uninsulated earth return. I know by experience that under such conditions the earth return will generally, on the whole, make a much better 'earth' than would be possible by any smaller artificial 'earth.'"

The remainder of the last portion of Clause 5 provides that where no pipe is to be within 6ft. of the earth connection, and the company are unable to obtain permission to connect it with the earth connection, they shall provide a non-conducting screen, so that no current may pass between the pipe and the earth connection without traversing at least 6ft. of earth. If the owners of the pipe are unwilling to allow it to be connected to the negative terminal of the generator, then they themselves ought to take all risks resulting from this non-connection.

Both Prof. Fleming and the committee of the Tramways Institute, as do most other people, find a difficulty in arriving at the meaning of the sixth clause—where the company shall "separate the uninsulated return from the mass of the earth." To all ordinary minds this reads, you must insulate your return. Paragraph (*c*), says the report, "is most delightfully vague. The company are to adopt means for reducing the difference produced by the current between the potential of the uninsulated return at one point and the potential of the uninsulated return at the other point. The difference of potential between any two points on the return depends simply upon the resistance of this return and the current flowing through it. If the Board of Trade chose to define what minimum resistance shall be allowed, well and good; but no person can possibly attach any definite meaning to the clauses, and no tramway company would be able to ascertain when they had complied with it and when they had not."

With regard to the amount of current to earth (*vide* first condition—Clause (*d*), No. 5), that depends upon the resistance of the earth return. The second and third conditions, says the report, "have reference to the direction and magnitude of the E.M.F. between the return and any pipes in its neighbourhood, and they stipulate that the current shall always be from the return to the pipes, and not *vice versâ*; but it is impossible for the current to flow out of the pipes into the return at one place, without flowing out of the return into the pipe at some other place, and unless the uninsulated return has a zero resistance it will not be sufficient simply to connect the pipe system to the negative terminal of the generator. In my opinion, all these two regulations and all their conditions are very academic, and are not based upon a practical experience of what does or may happen in such cases. If uninsulated returns are to be allowed at all (and they have been allowed by the joint report), then there is only one way by which the difference of potential between the ends of this uninsulated return can be connected down, and that is by making the resistance low enough. In order to prevent the escape of the current out of the return into the neighbouring earth, and so, by passing through pipes, producing, in the course of time, electrolysis, the practical remedy would be to embed the return in as highly conducting a soil or surrounding as possible; that is to say, laying an uninsulated return in a broad channel either between the rails or just outside, which is filled in as compactly as possible with gas coke, or some other highly conducting material, but of less specific resistance than the copper of which the return is composed. This connecting envelope, as it may be called, would then be traversed by leakage currents from the return, but it would tend to preserve these currents in a certain channel, and prevent them from escaping into the surrounding earth. Such an auxiliary conductor, as it may be called, would perform the function of limiting the spread

Digitized by Google

of the leakage current. Where the tram line forms a curve, something might be done to limit the spread of any leakage current by such a conducting channel, laid on the inner side of the curve, which I believe would have the effect of limiting the spread of the leakage current outwards. I do not think that these regulations, Nos. 5 and 6, are capable of being carried out in practice, neither do I think that it would be possible, as a practical thing, to go exploring about the neighbourhood of every tramway with a galvanometer, to find out if any electric current is flowing to every pipe instead of from any pipe. Where we know pipes are laid down in the neighbourhood of an electric tramway, a far better preservation for the pipe would be secured by thickly tarring or painting the same with a thick coating of pitch when they are laid down."

Clauses 7 and 8 and 9 do not call for much comment, though 7 and 9 are seen to contain unnecessary conditions. It is thought in Clause 10 that one ampere per mile would form a far more practical limit than the 100th of an ampere, and in Clause 11 it is pointed out that one megohm per mile would probably require some great care to attain, but that the insulation resistance of ten megohms per mile of line, returns, and feeders is impracticable. Upon Clauses 18 and 19 the report reads as follows:

"Clause 18 provides five conditions to be complied with in those cases in which the line and return are both laid in a conduit. According to the conditions, the conduit is to be so constructed as to admit of easy inspection and access to the conductors obtained therein. These points are exceedingly vague, unless the Board of Trade define much more strictly what is meant by easy access. It is to be so constructed as to be readily cleared of accumulation of *débris*. The companies may safely be trusted to do this for themselves; also to make such arrangements as to render it secure from water. The conduit, if formed of metal, is to be connected together metallically. This is what would probably be done. The last condition provides for the case of a conduit formed of non-metallic material, and stipulates that a non-conducting screen shall be placed between the conduit and any pipe. This, I think, is an entirely erroneous principle; what ought to be done is to bury the conduit in a deep channel filled with coke, made as highly conducting as possible. I do not believe that any screening of this kind, even if it could be practically carried out, would be effective."

"Clause 19 provides that the company should keep records of their operations. The general effect of these regulations on my mind is to produce the impression that the Board of Trade have taken gas and water pipes and single-wire telephone systems most particularly under their care, and that in the framing of these regulations due weight has not been given to the recommendations of the Joint Committee that as far as possible telephone and telegraph wires were to be protected from stray earth currents by duplicating the telephone and telegraph wires. I think that a great effort has apparently been directed towards preserving gas and water pipes from destruction by stray currents. The only effective way to prevent destructive stray currents from passing out into the general earth is to provide for them a conducting circuit of higher conductivity than the earth, and I think that this can most practically be done by burying the insulated returns in broad channels which are packed in with coke dust. After all, the real question as regards the telephones, even assuming them not to be provided with complete metal returns, is how much current can be sent through the earth without creating a disturbance in telephones in that neighbourhood. On one occasion I had the opportunity of carrying out an experiment on a large scale, in which 100 amperes were passed through an insulated conductor of one ohm and brought back by an insulated return of one ohm resistance, which was well earthed both at home and far end. Under these conditions there was a difference of potential of about 100 volts between the home and distant earth-plates. It was found that about seven amperes flowed back through the earth when the connection at both ends was made to gas or water pipes. But it is obvious it is not safe to draw conclusions from this experiment as to what would universally happen. Suppose we take the case of a tram line three miles long, the maximum current from the return at one time being estimated not to exceed 300 amperes. Supposing that the uninsulated metallic return of half a square inch in section were put down, the resistance of this three miles would be a quarter of an ohm, and the difference of potential produced between the home and far ends of the uninsulated metallic return would thus be about 80 volts at a maximum. Such a difference of potential between two places, three miles apart, might, under some conditions, be sufficient to make a return flow through the earth of about 10 amperes. Where these 10 amperes would go, and what they would do, would depend entirely upon the nature of the surrounding soil, but my opinion is that any practical return through the neighbouring earths might be considerably, if not entirely, limited by embedding this metallic return, or by including it on both sides between either fairly good conducting channels, such as would be formed by filling in the excavation in the ground a few inches wide and two or three feet deep, with coke, well rammed in, and forming, as it were, an auxiliary channel, which would take up the stray current and prevent it from penetrating into the neighbouring soil. The worst point about these regulations is their extreme vagueness, in some respects. The Board of Trade do not define what difference of potential they will allow to exist as a maximum between the points of the earth return, one mile apart. It seems to me that they should do this, and then there would be something definite on which to base calculations. Taking these regulations as I find them, I think it would be very difficult for any consulting engineer who was projecting an electric tramway system to know whether his arrangements would, in the end, satisfy the Board of Trade rules; and unless engineers are able to make such particular determinations, it is perfectly obvious that the effect of the regulations would be to greatly retard commercial enterprise in this respect. Vagueness in regulations of this kind is really, therefore, more fatal to commercial enterprise than great strictness combined with extreme definiteness; because, if we know what standard we have to reach, it is then possible to say whether in the present state of the art we can reach it; but if the conditions to be complied with are characterised by vagueness, then it is not possible to make the necessary determinations of cost with any certainty, or to say whether the scheme will meet with final sanction when completed."

The Tramways Institute has discussed, and we believe its committee has almost settled, the draft suggestions and alterations to be brought before the Board of Trade. Many of these are verbal, many of importance. Thus it would prefer that the word "steady" should be struck out of the first regulation, and "contiguous" take the place of or be added to "between" in the third and fourth. In the fifth clause, authority for modifications should be retained by the Board of Trade, and it might read,

Digitized by Google

"shall be placed 20 yards apart or such less distance as may be sanctioned by the Board of Trade." Further, in the same clause, instead of 4in. water-main, read 3in., and add, "unless with the sanction of the Board of Trade." Other suggestions are made, the general tendency being in the direction indicated by Prof. Fleming's report. The same statement applies to Rule 6, where it is pointed out that considerable difficulty is encountered in obtaining earth of the required low resistance of one ohm. In many places the ordinary telegraphic earth-plate has been known to have a resistance of from 50 to 70 ohms. It is thus easily seen that for tramway purposes the difficulty of getting an earth of less than five ohms might be considerable. To the Clause 6 (*i*) it is proposed to add after "10 amperes," "per mile of tramway." With regard to Regulation 7, it is suggested that the atmospheric changes, such as a heavy rainfall or an extremely dry day, may considerably affect the total conductivity of the uninsulated metallic return and the earth in which it is laid. The difference between this conductivity on a wet day and on a dry day may be considerably more than 15 per cent., and it is asked how such a test as is here stipulated shall be applied to eliminate the question of the earth's conductivity under these varying conditions. In Regulation 9, it is pointed out that every connection bar will form an additional point of leakage. This rule and the next are at variance, as is No. 10 with No. 11. Rule 14 is held to entirely do away with all the advantages in the recommendations of the Joint Committee. Rule 19, it is thought, will largely increase the cost of management—for example, many short lines could hardly afford to employ the skilled electrical ability required, and the daily and periodical tests required with sufficient accuracy to be of any value.

We have thus briefly, and we trust not too voluminously, directed attention to the points which appear to various committees prejudicial to electric traction.

FAULTS IN DYNAMOS.

(Concluded from page 121.)

IV. Dynamo Producing Excessive Noise or Vibrations while Running.

When too much noise or excessive vibrations are produced during the running of the dynamo, the cause should be immediately sought for, and a minute examination of the machine made. As a rule, the fault will be found to proceed from the following causes:

A. Loose screws.
B. Jarring of the shaft, from the edge of the drum or the belting against the bearings.
C. Badly balanced armature or drum.
D. Armature jarring against the pole-pieces.
E. Joint of the belt jarring on the drum.
F. Humming caused by the teeth of the armature core when passing the pole-pieces.
G. Bad adjustment of the brushes, causing them to grind against the commutator.

The vibrations may also arise from the dynamo not being firmly bedded.

A. Loose Screws.—A minute examination of all parts kept in their places by screws, such as the bearings, drum, etc., should be sufficient. This defect, which is of frequent occurrence, may be easily prevented if all the screws and movable parts are looked at each time the dynamo is started.

B. Jarring of the Shaft, from the Edge of the Drum or Belting against the Bearings.—A simple examination will show this. It may be remedied with the lathe, by shifting the pulley, or by stretching the belting, and seeing that the latter neither slips on the drum nor rubs against the journal. Sometimes the same result may be obtained by filing the journal and bearing, on the drum side.

C. Badly-Balanced Armature or Drum.—If while the dynamo is running the hand is placed upon the base-plate, strong vibrations, varying with the speed of the dynamo, will be felt. The armature and drum must be examined separately. Lift out the armature, and place it, as shown by Fig. 7, on two perfectly level metallic knife-edges, arranged so that the spindle can turn freely upon them. When this is done the armature should be given a slight impulse backwards and forwards, and if one side is heavier than the other it will have a tendency to descend.

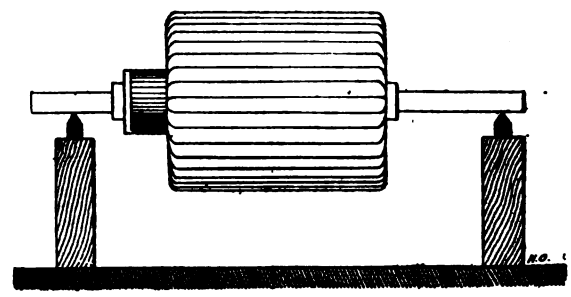

Fig. 7.

When the fault is found to exist in the armature, an equivalent weight of lead may be fixed *very firmly* to the lighter side and the balance restored. If the fault is not in the armature, proceed in the same way with the drum.

D. Armature Jarring Against the Pole Pieces.—Badly-fixed winding may cause this. The armature should be turned and carefully examined to see if it presents any appearance of this, and, above all, if there is a space of at least 1·5mm. between it and the pole-pieces. It will also be seen, if the armature is turned slowly with the hand, if any part of it touches the pole-pieces. Any projecting pieces should be flattened down, or the wires properly secured. If nothing else can be done, the parts of the pole-pieces making friction with the armature should be filed away.

E. Joint of the Belt Jarring on the Drum.—When the joint is badly made, and is thicker than the rest of the belt, it will make a noise each time it passes over the drum. The remedy is to make a new joint, or use an endless belt.

F. Humming Caused by the Teeth of the Armature Core When Passing the Pole-pieces.—With toothed armatures there is always a slight humming when the dynamo is in motion. This noise, however, is not due to a fault, and need not be taken any notice of, except when a dynamo is started for the first time, and only then if the humming is excessive. It may then proceed from defective construction, such as the cross-section of the core teeth being too short, or the ends of the pole-tips being too long, etc.

When the humming increases greatly in a dynamo which has hitherto been in good order, it may be the result of too strong an exciting current. This can be readily ascertained and as readily remedied by increasing resistance in the exciting circuit.

G. Bad Adjustment of the Brushes, Causing them to Grind Against the Commutator.—This can be detected by the ear, and sparking may also occur. Bad adjustment of the brushes, inequalities on the surface of the commutator, brushes too hard (or flinty when use is made of carbon brushes), or at an improper angle, may each and all give rise to considerable noise. Once the cause is ascertained the defect may be remedied by carefully oiling the commutator, re-turning it in a lathe, filing it, or rubbing it down with sand-paper, or, finally, by readjusting the brushes and placing them properly in the brush-holders.

V. The Armature Not Turning at its Normal Speed.

The speed of the dynamo can be found with a speed

Digitized by Google

indicator, and as the engine does not alter, it will then be seen whether the speed is reduced or accelerated by the dynamo. The fault may proceed from:

A. Surcharge from the dynamo.
B. Short-circuit in the armature.
C. Bearings too tight or foreign matter in the journals.
D. Friction of the armature with the pole-pieces.

A. SURCHARGE FROM THE DYNAMO.—A reduction of the armature speed is accompanied by excessive sparking and heating of the journals and armature. Furthermore, the belting is unduly tight, and the ampere-meter will show an excess of current. The reduction in speed is merely a result of the fault. For procedure, see "Surcharge from the Dynamo," Part II.

B. SHORT-CIRCUIT IN THE ARMATURE.—This fault is, among other things, characterised by unusual heating of the armature and heavy sparking at the brushes. Proceed as in "Short-circuit in the Armature or Commutator," or as in "Short-circuit in the Winding of the Armature."

C. BEARINGS TOO TIGHT OR FOREIGN MATTER IN THE JOURNALS.—In this case the journals will heat greatly, and the procedure should be as in "Metallic Dust or Foreign Matter in the Bearings," "Imperfect Bearings." The fault may also be due to want of lubrication (see "Defective Lubrication").

D. FRICTION OF THE ARMATURE WITH THE POLE-PIECES. See "Armature Jarring Against the Pole-pieces." The fault is not only shown by reduced speed but by noise.

SYNOPSIS.

Having described the principal causes of the irregular working of a dynamo, it may be useful to tabulate them for purposes of reference. They are as follows:

FAULTS OF FREQUENT OCCURRENCE IN DYNAMO MACHINES.

PART I. THE DYNAMO GIVES NO CURRENT.

A. Remanent magnetism in the field too feeble.
B. Defective contacts.
C. Short-circuit or bad insulation in the internal or external circuits.
  (a) Badly-insulated terminals.
  (b) „ „ brush-holder.
  (c) „ „ armature coils.
  (d) Short-circuit in the armature coils.
  (e) Short-circuit on the commutator.
  (f) Short-circuit at some point of the wiring.
D. Open circuit in the dynamo or external circuit.
  (a) Disconnection in the field coils.
  (b) „ „ internal circuit.
  (c) Brush not making contact.
  (d) Disconnection in the external circuit.
E. Reversed field-magnet coils.

PART II. PRODUCTION OF STRONG SPARKS AT THE BRUSHES.

Causes of serious sparking at the brushes are:

A. Surcharge from the dynamo.
  (a) Excessive voltage.
  (b) Great excess of current.
  (c) Bad insulation of the external circuit.
B. Bad adjustment of the brushes.
C. Bad state of the commutator.
D. Bad state of the brushes or brush-holders.
E. Disconnection in the armature circuit.
F. Short-circuit in the armature.
G. Defective insulation of an armature coil.
H. Weak magnetic field.

PART III. ABNORMAL HEATING IN THE INTERNAL CIRCUIT.

A. Heating of the armature.
  (a) Excessive current in the armature.
  (b) Short-circuit in the winding of the armature.
  (c) Foucault currents in the armature core.
  (d) Humidity in the armature coils.
B. Heating of the field magnets.
  (a) Excess of exciting current.
  (b) Humidity in the field coils.
  (c) Foucault currents in the pole-pieces.
C. Heating of the journals.
  (a) Defective lubrication.
  (b) Metallic dust or foreign matter in the bearings.
  (c) Bent, badly turned or finished shaft.
  (d) Imperfect bearings.
  (e) Drum or shaft making friction with the bearings.
  (f) Belting too tight.
  (g) Armature too near one of the pole-pieces.

PART IV. DYNAMO PRODUCING EXCESSIVE NOISE OR VIBRATIONS WHILE RUNNING.

A. Loose screws.
B. Jarring of the shaft, from the edge of the drum or belting against the bearings.
C. Badly-balanced armature or drum.
D. Armature jarring against the pole-pieces.
E. Joint of the belt jarring on the drum.
F. Humming caused by the teeth of the armature core when passing the pole-pieces.
G. Bad adjustment of the brushes, causing them to grind against the commutator.

PART V. ARMATURE NOT TURNING AT ITS NORMAL SPEED.

A. Surcharge from the dynamo.
B. Short-circuit in the armature.
C. Bearings too tight or foreign matter in the journals.
D. Friction of the armature with the pole-pieces.

It is hardly possible to give fixed rules with regard to all the faults which may occur in a dynamo machine, but it is hoped that the foregoing will be found of some service.

CHARGING STATION FOR AUTOMATIC RAILWAY CARRIAGE LAMPS.

Some years ago (see the *Electrical Engineer* under date of September 6, 1889) we described and illustrated in considerable detail the construction and mechanism of the automatic railway carriage reading lamps devised by Messrs. Davies and Tourtel, who took out patents for the methods and appliances used. Although so long a time has elapsed since they were thus first noticed, the intervening period has been by no means wasted or lost in a tardy development of these lamps on a commercial scale. Many great improvements may be seen to-day in the actual mechanism employed to operate each lamp, and in such practical features as the containing cases, position of light, mode of attachment to the carriage, etc., whilst, in addition, the stages through which the invention has passed have brought into its control men of influence and standing, by whose efforts it is now in active operation on the Metropolitan District Railway. The time cannot, it is thought, be long delayed when it will also be adopted on the Metropolitan Railway, more especially for the Circle trains.

Seeing that we entered with some amount of detail upon the lamp mechanism itself—as already stated—when it was first devised, it is hardly necessary now to again describe it, even although considerable improvements have been effected. Of course, the practical principles involved are the same, and those who wish to see the manner of cutting in or out the light or of rejecting money from the apparatus when defective or exhausted may be referred to our former description.

The arrangements which have been made to recharge the exhausted batteries present, however, some amount of interest, and the following details are therefore given.

In view of substantial developments, and also to adequately cope with existing demands, the owners of this device—the Railway Automatic Electric Light Syndicate, Limited—have erected an admirable charging station at Mill Hill-park, near Acton, and close alongside the District Railway Station, to which there is connection by means of a siding.

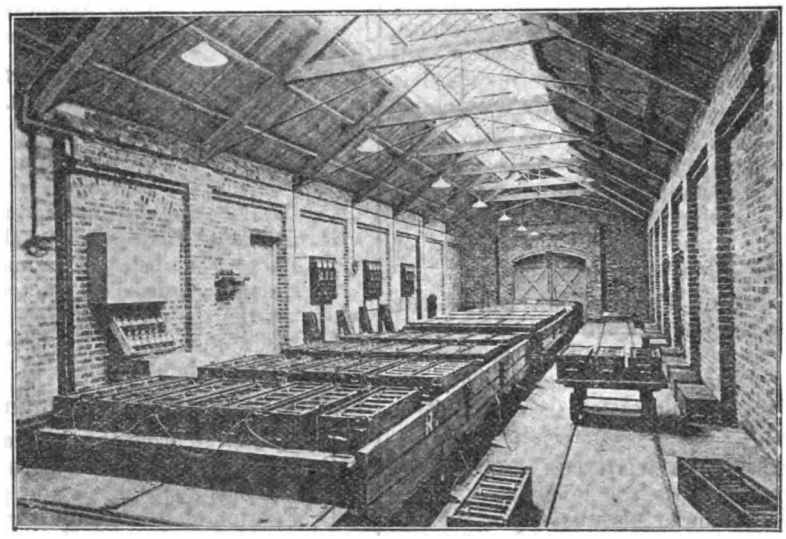
The building itself is of brick, and consists of two long sheds or bays roofed over with slate, and having ridge louvres for ventilation where necessary. The whole of one bay is occupied by the charging line and platform.

Digitized by Google

As may be seen from the plan, the siding from the main line runs into the building through large folding doors, and then passes straight up the centre of the bay. On each side are raised wooden platforms, joined at the far end, so as to be continuous, in fact, on the three sides. Down one side runs a small narrow-gauge line of light rails, upon which is placed a trolley for carrying the batteries to and fro.

them quite easily. The separators employed at first were of ebonite ∧ section, but it was found that these were rather apt to flatten out and allow adjacent plates to come into contact. Hence the section was altered to the following ⊓, of rectangular shape, and no more trouble has been experienced on that score.

Each truck is arranged to hold four train sets of seven batteries each, which are charged in series without removal

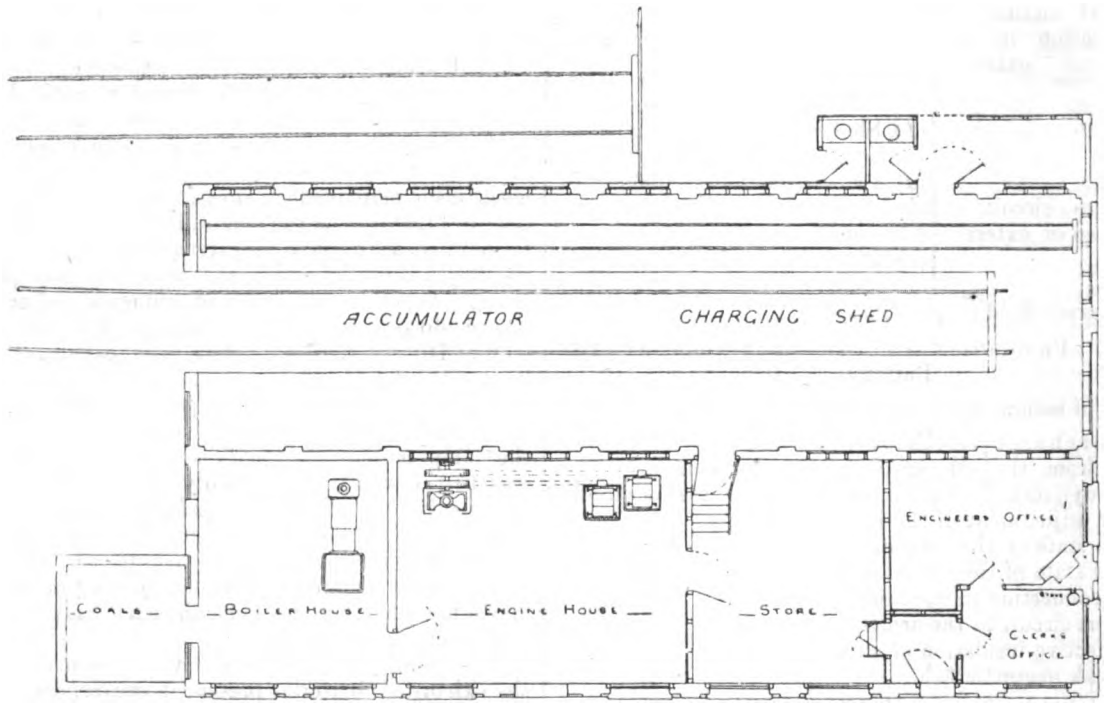


Interior of Charging Shed—Mill Hill Park Station.

The siding has accommodation inside the shed for three flat-topped railway trucks without sides, the ends being arranged to fold down so as to form a continuation of the platform. Some half-dozen such trucks are already in use, and at the time of our visit to the station three, fully loaded with the sets of batteries, were being charged: one, we were told, was at the sub-station at Whitechapel, whence the batteries are distributed to the trains; one was at Lillie Bridge, under similar

from the truck; a simple form of connection being used which enables the batteries to be so rapidly coupled together that the charging can be commenced a few minutes after the trucks enter the shed.

In the trains the batteries are discharged in parallel by means of connections between the carriages; the object being to keep all the batteries in each train set in the same condition of charge, so that, although the batteries from different trains may have reached different stages of



Plan of Charging Station.

circumstances; and the sixth was outside the charging station, snugly covered with a tarpaulin, and ready to go out with a freshly-charged load.

The battery sets themselves contain each six cells of E.P.S. plates specially designed and made for the work, having a capacity of 72 ampere-hours. The containing-boxes are of varnished teak, with handles at each end, and teak lids: their weight is considerable, as may be supposed, but a couple of men are able to manage

exhaustion, upon charging a truck load, all the batteries in each train set will become fully charged simultaneously, and can then be switched off without interfering with other train sets requiring a longer charge—thus economising power. Another great advantage of working the batteries in parallel in the trains is that (owing to the fact that each reading-lamp contains a switch which, upon being operated, is held by an electromagnet during the duration of the light) any temporary break in the circuit,

such as the fracture of a battery lug, would permanently extinguish the light were it dependent upon a single battery for its supply; but, of course, when the batteries are arranged in parallel, the failure of one, or even several, would not affect the light.

Although the District Railway trains consist of nine coaches, a battery is placed only in each of the second and third-class carriages, because, owing to the lowness of the seats in the first-class carriages, there is no room available.

It is found already, by the way, that the chief receipts from passengers are derived from the second-class carriages, presumably because the first-class are somewhat better lighted than usual by gas, whilst third-class travellers as a rule only take the trains for short distances. Of course we do not now touch in any way upon the whole question of railway carriage lighting, or the advisability of a private outside interest undertaking such work instead of the railway company itself.

The staff required for working the installation of 2,500 lamps on the District Railway is very small: two men stationed at Whitechapel terminus being sufficient for all the battery removals required, as one charge lasts a train from a week to 10 days.

The necessary current for recharging the accumulator sets is obtained from two 10½-unit (100 amperes at 105 volts) Elwell-Parker dynamos driven in parallel by belting from a 30-b.h.p. vertical high-pressure steam-engine made by Messrs. Marshall, Sons, and Co., Limited. The latter is fed from a loco.-type multitubular boiler from the same makers, space being left in the boiler and engine rooms for a duplicate set throughout—boiler, engine, and dynamos. From the generators the current is led to a main switch-board, and thence to three regulating-boards in the adjacent charging-shed—one for each truck on the siding. By this means the current and voltage may be watched and the generating plant properly regulated, and 12 battery sets, of 42 cells each, are charged in parallel at the same time.

Taken as a whole, this station is extremely creditable to its designer; the general plan is convenient, and the details are well worked out. In two words, we should sum up its chief qualities as being "neat" and "substantial." Much credit is due in this connection to the managing engineer, Mr. J. Tourtel, and if the business of the syndicate is carried on with the same thoroughness that characterises its supply station, one would feel obliged to prophesy for it a considerable amount of success.

THE THEORY AND DESIGN OF THE CLOSED-COIL CONSTANT-CURRENT DYNAMO.*

BY HENRY S. CARHART.

Constant-current dynamos for arc lighting have been in practical use for the last 15 years. Most of the public lighting by arc light service has been done with dynamos of the open-coil type. They secured the field at an early day in the development of this branch of electrical industry through the inventive genius of Charles F. Brush and the splendid ability of his business associates. This success was repeated a little later by the equally brilliant achievements of Profs. Thomson and Houston and the phenomenal management of the company formed to exploit their patents. Aside from any question of inferiority, it is therefore easy to see why the closed-coil dynamo for constant currents has remained so long in the background. It has not received the attention to which it is justly entitled, and has not been investigated with the thoroughness and skill which it merits. It is not my purpose to draw any comparisons whatever between open and closed coil armatures. The former is entitled to that consideration which long-continued and satisfactory service in public and private illumination has earned for it. But the latter is making its way into public favour, and it has certain peculiarities which make it an interesting subject for study. If I were to draw attention in this paper to comparisons between dynamos of different types, it would be between those for constant potential and those designed for constant current, both with closed-coil armatures. For in almost every particular the latter is diametrically opposite to the former. The one is designed to give a constant potential; the other a constant current. One is shunt or compound wound; the other series wound. In the one the resistance of the armature is as low as possible in comparison with the field; in the other, the armature resistance is relatively large compared with the field. The one has a sensitive field and is worked below the saturation point; the other should have a staple field, which is worked well up on the saturation part of the curve of magnetisation. Ideally the characteristic of the one is a horizontal line; that of the other a vertical line. In the constant-potential machine the brushes are set only slightly in advance of the theoretical neutral line on plane; in the constant-current dynamo the brushes may be at any point on the commutator according to the load, while the neutral plane remains fixed. When the load decreases with the one, the brushes, if moved at all, are rocked backward for sparkless commutation; when the load decreases with the other, the brushes are rocked forward for minimum sparking or even sparkless commutation and constancy of current. When the load increases on the one, it governs by an increase of induction from an increasing field; when the load increases on the other, it governs by decreasing the counter E.M.F. in the coils between the brushes and the neutral plane. In the one, armature reaction is purposely reduced to the smallest dimensions; in the other, it is purposely made of considerable dimensions. In these comparisons it is assumed that the speed is constant in both cases. If some of these statements are not self-evident, they will be supported, I hope, by subsequent portions of this paper.

The Neutral Plane Independent of the Plane of Commutation.

By neutral plane is meant a plane passing through the axis of the armature and so situated with reference to the poles of the field magnets that when a coil of the revolving armature is carried across it the E.M.F. generated changes direction. This plane intersects the armature in a straight line, but it may broaden out more or less into a surface of small lateral dimensions.

The plane of commutation is a plane passing through the armature axis and the points of contact of the brushes on the commutator. It is the plane joining the poles of the armature considered as an electromagnet. This latter plane of course shifts with the brushes, since the poles of the armature are the points at which the current enters and leaves the armature, and these are necessarily the points or surfaces of contact of the brushes with the commutator, assuming that the connections from the armature to the commutator run directly out parallel to the shaft. To state the proposition now under discussion in the form of a question, Does the neutral plane shift when the brushes are shifted forward or backward? If we were to make answer from the assumption that the resultant of two impressed magnetisations or magnetomotive forces may be obtained in the same manner as the resultant of two forces by means of the triangle of forces, we should probably conclude that the neutral plane rotates forward with a forward movement of the brushes. But experiment along several different lines shows that this conclusion is in error. If we were to apply to the solution of this problem the principles derived from constant-potential machines, we should be forced to the conclusion that to maintain sparkless commutation at the brushes the lead of the brushes beyond the neutral plane should be constant, since the current remains constant, and, therefore, that any attempt to govern for constant current by rocking the brushes must be attended by destructive sparking, unless at the same time the field is greatly modified. But these conclusions are also erroneous. We must therefore first establish the facts, and then make a theory to fit them.

The fixed position of the neutral plane I have determined on a 10-light machine in two different ways.

First Method.—Four turns of No. 16 silk-covered magnet wire were wound around the armature ring as an exploring coil. One end of this coil was soldered to a copper band or ring fastened on the commutator and insulated from it by several thicknesses of mica. The other end was soldered to a piece of brass let into a fibre

* Paper read before the Franklin Institute, December 26, 1893.

Digitized by Google

collar placed around the commutator. One extra brush was fastened to one of the main brush-holders, and rested on the copper band. The other extra brush rested on the fibre collar and could be attached to any point of a circular scale made concentric with the commutator. A twisted cord ran from these two brushes to a telephone at some distance. When the dynamo was running, the movable brush, which rested on the fibre and made contact with the brass strip every revolution, was moved around the circle till a minimum sound was heard in the telephone. The exploring coil was then on the neutral plane at the instant when the brush made contact with the strip. Motion of the brush either way caused the sound to increase in loudness. The position of the exploring coil for minimum sound was found to be about 5deg. in advance of the normal plane intermediate between the pole-pieces; and its position did not change from full load to no load as far as could be detected by this method.

Second Method.—To the brush-holders was attached an insulating ring slotted on the periphery at every 10deg. on a milling machine. It was made as nearly concentric with the commutator as possible. A third brush-holder was placed in the successive slots, and the potential difference between it and one main brush was measured in its several positions. These measurements gave the

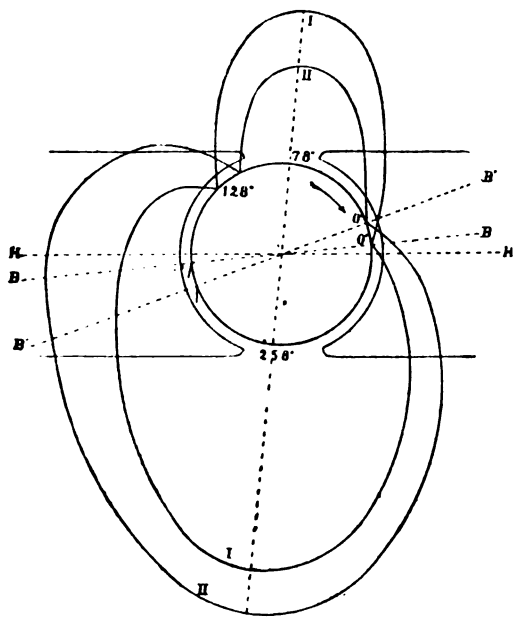

FIG. 1.

integrated potential difference between the main brush and successive points on the commutator all the way around the circle and back to the starting-point. This was done with no load on nearly short-circuit with a load equivalent to three lamps, and finally with a load equivalent to nine lamps—the current being 10 amperes in each case. The results in the first two cases are plotted around a circle in Fig. 1. Positive values, or those in which the potential of the third brush was higher than that of the main positive brush are set off outside the circle in the upper part of the figure, while negative values are set off outside in the lower section of the diagram. The direction of rotation is clockwise. With no load the highest positive potential was about 78deg. behind the positive brush. From this point it fell again, and at 128deg. it was the same as that of the positive brush. For all the coils between 0deg. and 128deg. the integrated positive and negative E.M.F.'s exactly equal each other. The neutral plane falls evidently 78deg. behind the brush, or the brushes may be said to have a lead of 78deg. with no increase in sparking. A negative maximum occurred at about 260deg., and the potential difference between the positive and negative maxima was 644 volts. The same potential difference was found by direct measurement when two extra brushes were set at these points.

With a load equivalent to three lamps the brushes were rocked back 15deg. to bring the current to 10 amperes. Hence the zero of this curve begins 15deg. back from the zero of the first curve. Again the observations are plotted, and the positive maximum falls at the same place on the circle, and, therefore, at the same place on the commutator. The two maximum points are at about 65deg. and 245deg. from the positive brush, and the two potential differences are 168 and 456 volts. Their sum this time is 624 volts, a little less than with no load. With the highest load carried the brushes were rocked backward about 50deg. farther, and the lead was then about 15deg. The extreme potential difference obtainable this time did not exceed 600 volts. So far as can be discovered from these curves, the neutral plane remains fixed, while the brushes move around the commutator to adjust to a constant current. I find no evidence in them that the forward movement of the brushes to control the current causes the neutral plane to move with them. As the brushes advance with a diminishing external load they put between them and the neutral plane an increasing number of armature-turns generating counter E.M.F., and it is a striking fact that when the field coils are not cut out, the back turns on the armature cut down the potential difference between the brushes not by a counter magnetomotive force apparently, but by counter E.M.F.; for the maximum potential difference to be found on the commutator is no less on no load than on full load, showing that at least as many lines of force traverse the armature core with the brushes far forward and with many back armature-turns as with the brushes in the position for maximum load and with the back turns reduced to a minimum.

THREE METHODS OF GOVERNING.

Assuming still practically constant speed, we next enquire into the methods employed to maintain a constant current without appreciable sparking by rocking the brushes around the commutator cylinder.

In one machine the brushes are moved automatically by means of a small electric motor, and at the same time field coils are successively cut out as the brushes rock forward with a light load. A pair of brushes is used on each side, and they are kept at a fixed distance apart. By these combined means the machine can be run on short-circuit with the normal current and without sparking.

Another system leaves the field coils constantly in circuit, but employs two pairs of brushes and varies the angular distance between the members of each pair when the brushes are moved. The movement of the brushes is effected mechanically in response to any change in the main current till the current is brought back to the normal value. In these machines the spread of each pair of brushes, or what is sometimes called the overlap of the brushes, is lessened as they rock toward the polar centres. Very satisfactory results are secured in this way.

In the third class of machines only one pair of brushes is used, which lap over about two or three commutator sections, and the regulation of the current is effected solely by the movement of this one pair without change of overlap and without disturbance of the ampere-turns on the field. The brushes are moved mechanically by means of an automatic regulating device. No less satisfactory results appear to be secured by this method than by the others, while the mechanism as a whole is somewhat simpler.

I have described these three methods for the purpose of pointing out their bearing on the theory and design of closed-coil Gramme rings for constant currents. The important question is not how to get the necessary E.M.F. with such a dynamo, but how to vary that E.M.F. in response to the varying demands of the external circuit, without injurious sparking at the brushes.

The E.M.F. is controlled in all three of these methods by rocking the brushes, and the other differences in the devices are made necessary for the suppression of the sparking. This brings us to a consideration of the most intrinsically interesting topic of the paper—viz., the conditions necessary to suppress sparking and the features of design required to furnish them.

(To be continued.)

Fatal Accident.—Henry Ward, aged thirteen years, while assisting to repair some electric wires at Prescot, near St. Helens, came in contact with an exposed wire, and was instantly killed.

BLACKPOOL TRAMWAYS.

Blackpool is destined to be a centre of attraction. No doubt its local magnates are not angels, but, on the whole, they are thorough business men, having an ample supply of that North Country commodity which usually results in benefiting Number One. The benefit of the greatest number is a very good election cry, though keen analysis shows that number to be Number One. We have heretofore pointed out that Blackpool is comparatively a small town, yet it is omnivorous in its capacity to attract visitors. It lives upon visitors, it thrives upon visitors, its magnates grow rich upon visitors; hence their great desire not to frighten the goose that lays the golden eggs. At any cost its name must be kept before the seaside-going public. Thus we find it early in testing that which is new and may be attractive. To keep well abreast of the times is a motto never forgotten, and we must say that it pretty consistently manages to take the lead of all rivals. This is as it should be, and such a policy is commendable, so much so, that any tendency to rest and be thankful, or to take retrograde steps, must be deplored and the evil effects pointed out. What does it matter if rents and rates are high provided a commensurate return is obtained? As a financial critic reminds us, why agonise when an expenditure of a hundred pounds never fails to bring a return of a hundred and five? You have only to spend enough hundreds to become rich. Well, that is very much the condition of Blackpool. Again and again of late years in all departments of trade it has been shown that the giving of value for money is never the road to failure. Blackpool must continue to give value, and it will rise still higher than at present in the regard of those whose visits pour into its coffers a perennial stream of gold. How has Blackpool shown its progressiveness, its farsightedness, except in providing for the comfort and the pleasure of its visitors? It has its Winter Gardens, over which genial William Holland presides, as well as other similar attractions; it has its Blackpool tower, which is fast approaching completion and earning power. Then its three piers, and its theatres and music halls, are private adventure concerns, but the town in its corporate capacity has furnished the best-lighted length of parade in the world, and has now in its power to furnish the best tramway of any parade. History tells us that some few years ago an electric tramway was projected and carried out along the Blackpool sea-front, that the system was a conduit one as designed by Mr. Holroyd Smith. Be it remembered Mr. Holroyd Smith's designs were made in very early days of traction work, and of conduit systems especially; that it was therefore a pioneer design, which, although it might possess numerous good points, must necessarily be less perfect than one designed later, when greater experience had been obtained. It is, therefore, not to be wondered at that the troubles of maintenance and celeritous working increased rapidly with age, till they became so great as to cause a return, at least temporarily, to horse traction. Blackpool cannot afford to go back to horse traction per-

Digitized by Google

manently, at least if it is desirous of keeping up its reputation; therefore, the candid report of its electrical engineer ought to be welcomed. A careful examination of this report will show the causes of the troubles, and knowing the causes the remedies must, if known, be supplied, or if unknown be sought for. However, they do not seem to be of exceptional difficulty if we put aside that one great bugbear of traction work—the large variation in load. This cannot be effectually combated with ordinary gearing, and we would suggest a consultation with Mr. W. W. Beaumont, who, so far as we can learn, has carefully examined into this question, and designed gearing, described at the last British Association meeting, and in our columns September 22, 1893, which promises good results in practice. It ought not to be difficult to give this gearing a trial, and if found effective in practice, we should at once get rid of the major part of the troubles referred to in this report, such as the breaking of ropes and belts, the breaking of armature connections, and, in fact, all that class of troubles brought about by excessive and irregular strains. With regard to the making of joints and the use of salts as a flux when soldering, such a system ought never to have been passed in the original construction. Mr. Crompton in the very earliest days of electrical work strongly emphasised the uselessness of such joints; but it seems that here, as in other directions, where Mr. Crompton went out of his way to give words of caution his experience had little weight. If joints are made with salts as a flux, they must sooner or later fail and give trouble. It is well that Mr. Hesketh emphasises this as he does in giving the extent of life of such a joint at seven and a half years. The width of the slot is a matter shown by experience to be bad if less than half an inch. On the whole, it seems that the great difficulty is irregularity of strain, and that the working has shown minor faults of design and construction. The authorities should take heart, remedy these evils, and once more put their tramway into the proud position of being the best-equipped and most attractive of tramways owned by corporate bodies in the kingdom.

INSTITUTION OF ELECTRICAL ENGINEERS.

NOTES OF A TRIP TO THE UNITED STATES AND TO CHICAGO, 1893.

BY W. H. PREECE, C.B., F.R.S., PAST-PRESIDENT.

II. TELEPHONES.

(Continued from page 117.)

It should be explained here that the term "trunk" is adopted in America to indicate connections effected between one exchange and another within the same area. Connections between town and town are designated "long-distance" connections. The tendency is to depart from the principle of the multiple switch; and an extremely interesting experiment is being carried out simultaneously in Chicago, Buffalo, and New York to determine the merits of a new system of working called the "divided board." The divided board means this: There are two boards, the one called the answering board and the other the connecting board. The answering board contains the indicators and trunks, including those to the connecting board, and all local connections are treated as trunks through the connecting board. Thus, while each operator at the answering board attends to and answers only her 60 subscribers, and is able still to control all the trunk wires, the local spring jacks are duplicated on the connecting board, which may contain one, two, or three complete sections as the case may be, and are attended to by separate operators. All the business is thus trunked. The result is that the service performed for the subscribers for local connections is slightly retarded. On the other hand, the work done on the trunks is equally expedited. If 50 per cent. of the work done in the central exchange is trunk work, it is argued that if subscribers find that one-half of their work is expedited and the other retarded the expediting of the more important part will compensate for the retardation of the less important, and the general result will be beneficial. The chief merit of the divided board is that it reduces the "jacks," as the switch-holes are called. Seven sections of board with 42,000 jacks would replace 40 sections with 240,000 jacks in an exchange of 6,000 subscribers. I find opinion, however, divided upon this question; but the view is very general that when the multiple switchboard exceeds a capacity of 2,500 subscribers, it certainly introduces disadvantages and defects which must in some way or other be remedied.

Trunk Working.—The trunk working is wonderfully well done. In the first place, the connections between the different exchanges are very numerous. In the central exchange at Chicago there are 344 outgoing and 325 incoming trunks. There are 11 exchanges, and these exchanges are located as nearly as possible in the centres of the districts which they are designed to serve. The business of these offices, however, is by no means self-contained, and a very great amount of their work is in handling calls from subscribers in one exchange to subscribers in another. These are now handled by means of 954 trunk circuits extending between the various offices; the total number outgoing from each office being as follows: Main, 344; North, 34; South, 77; West, 74; Canal, 63; Yards, 61; Oakland, 68; Lake View, 26; Harrison, 59; Wentworth, 19; World's Fair, 80. In Boston, between their central station and Tremont Exchange—an exchange of 833 subscribers—there are 27 outgoing and 33 incoming trunks. The service between two exchanges is virtually a silent one. No question is asked, but instructions are given simply: "301 on North 273." This is spoken on a call circuit. The trunk operator—always a male—wears a headgear telephone, receives this instruction, and carries it out without a word being said, or a second lost. In some places the subscriber, if he wants a subscriber on another exchange, calls his own exchange as usual, and, on getting attention, says "Tremont." He is then placed in connection with the Tremont Exchange, and he himself asks for the number he wants. The former plan is, however, the more general one, and that which is preferred. There are always so many trunk wires available that the operator has rarely to say, "Wires engaged," or "Busy," which is the common expression. I never saw one case of the kind myself. The hourly maximum number of trunk calls between Boston (Main) and Tremont Exchanges was—From Boston, 557; to Boston, 475. The former averaged 20½ per circuit; the latter averaged 14½ per circuit. The result is that in places like Chicago, where there are 11 exchanges, and New York, where there are nine exchanges, the trunk working is done between them virtually as though the whole of the exchanges were centred in one big hall. The long-distance work is done in the same way. Only metallic circuits are switched on to the long-distance lines. The incoming trunk wires end in plugs, the outgoing trunk wires end in "jacks," so that when an operator hears "351 on Chicago 3," he simply takes up 351 plug and puts it in a Chicago jack without hesitation. If, however, all the Chicago jacks are busy—which he sees at once by the visual signal—he says "Busy," and the caller has to wait his turn. In my experience this occurred but rarely. When the calls were heard, the connections were made as rapidly as possible for it to be done, or as rapidly as one could wish that it should be done. In New York the Long-Distance Company and the New York Telephone Company are in the same building. A complete section of the New York multiple board is in the long-distance switch-room, so that connections are made direct between the long-distance lines and the subscribers. Usually a section of the multiple board in the local exchange is allotted for long-distance trunk work to the long-distance office, which may be elsewhere. It is so arranged that when a subscriber talks on a long-distance line his own circuit is entirely cut out from the local operating switchboard. There are a great many public call offices open in every city. There are 535 in New York. They call them "public pay stations." People pay tolls, and they come in and speak to the exchanges and get their connections through.

Long-Distance Working.—The long-distance speaking in the States is very popular and very successful. The opening of the circuit between New York and Chicago—a distance of nearly 1,000 miles—was so successful that they immediately found it necessary to erect two more circuits. There are now, therefore, three circuits between these two places. I tested these circuits, and found the working remarkably good. It was difficult to say

Digitized by Google

that it was better or worse than the working of our London-Paris line. The tariff for the long-distance work is based upon one cent per mile for five minutes' talk. The greatest distance that I found upon which speech was conducted was between Milwaukee and Portland, and between these places talking costs 11dol. (44s.) per five minutes.

Rate of Working.—I found that the customers dealt with by each operator varied very much in different towns. The following table will show this :

Town.	Customers per operator — Local.	Long-distance trunk.
Theoretical	100	6
Chicago.....	66	6
Buffalo	100	—*
Boston	70	3
New York, Eighteenth-street.....	50	6
Brooklyn	66	10
New York, Corlandt-street	60	—*

* I did not record the number in these two exchanges.

The daily calls per circuit also vary very much. The average per day over the whole country is 8·03. At Chicago, on one exchange it reaches to as many as 24·3; the mean for the whole town in January was 13·6, while in July it was 12·3. At Buffalo the mean is 6. It is interesting to note that the number at Buffalo is just the same as it was when I visited that place in 1884. At Boston the average number then was 5 ; it is now 12·6. While this average of 12 or 13 calls per day is not an extraordinary one, it represents great extremes in the use of telephones, which bring about complications which are at times difficult to meet. There are in the main exchange at Chicago at the present time several hundred telephones which are used more than 109 times each day. Nearly all this business is handled between the hours of 9 a.m. and 5 p.m. During the busiest hours of the day these instruments are in use almost continually. When calls are made for them, therefore, the only reply is that they are busy. As an example of this excessive use, my attention was called to the case of the Waukesha Hygeia Mineral Springs Company, telephone No. 929 South. A complaint was made by one of their branch offices that they could not reach the main office, the line always being reported to be busy. A record was made of the calls handled on this telephone, and in one day it was found to be used a total of 449 times, there having been 18 originating calls and 431 calls received. In one hour the telephone was used 51 times. This is, perhaps, the busiest line of which there is a a record. Telephones used by railway offices, wholesale houses of all kinds, hotels, and many other places, are apparently in use almost continuously in the busy hours of the day. Many such establishments have more than one telephone, some of them having as many as six. The subscribers per exchange in the exchanges that I visited are as follows : Chicago, 10,312, divided thus : Main, 4,912 ; South, 1,037 ; North, 996 ; West, 903 ; Canal, 434 ; Yards, 392; Oakland, 655 ; Lake View, 244 ; Wentworth, 46 ; World's Fair, 269 ; Harrison, 424. New York : Cortlandt-street, 4,500. Boston : Central, 3,545. The total subscribers in New York are 9,574, at Brooklyn 4,800, and at New Jersey 4,900, making a total for New York and district of 19,274.

Underground Work.—The statistics that I have given show how rapidly underground cables have come into use in the States. At the Chicago central exchange 76 cables, each containing 100 wires, enter the building and ascend up a shoot to the exchange-room. The conductor used is smaller than that adopted by us. It is only No. 19 Brown and Sharpe gauge. It gives 47 ohms resistance per mile, and it has a capacity of 0·68 microfarad per mile. The insulation must be 500 megohms per mile at 60deg. F. All cables before being used are very carefully tested, not only to see that they comply with the specification as to conductivity, capacity, and insulation, but also for what is called "cross-talk," by means of buzzers. There are no less than 14,034 miles of underground wire in New York. One hundred and sixty cables, each containing 100 wires, enter Cortlandt-street building—that is, 16,000 wires enter this exchange. In Boston 91 lead-covered cables enter—that is, 10,920 wires in all, for each cable carrier 120 wires. The cable are made for 50, 60, or 100 pairs of wires. The 50-pair cables have a diameter of 1⅞in., the 60 and 100 pair cables being 2in. and 2¼in. in diameter respectively. These cables are in all cases brought straight to distributing-boards in a room alongside the switchboard-room, and here they are brought to terminals in a way similar to that adopted by us, so that changes can rapidly be made. Subscribers' lines are so distributed among the sections of the switchboards that the work is distributed as uniformly as possible amongst the different operators. The dry-core or paper-insulated cable has proved to be a very great success, and is now universally adopted for telephone purposes.

Chicago.—I have given the number of exchanges and subscribers in Chicago. To provide for this service, there are : Miles of conduit, 48·02 ; miles of duct, or channel, 433·24 ; miles of cable, underground, 106·96 ; miles of wire, underground, 17,995·53 ; number of manholes, 888·0 ; miles of cable, aerial, 65·97 ; miles of wire in aerial cables, 5,184·70 ; total miles of wire in cables, 23,180·23 ; total miles of wire on poles, 7,958·0.

Switchboards and Indicators.—Great improvements in working have been made in consequence of the introduction of metallic circuits. Visual signals, like those employed by the Post Office Department, are coming in. Dirt in the gear was a great source of trouble. False busy signals were frequently received. Now a third wire and an automatic restoring indicator has made the busy test reliable. The visual signals on trunk wires are assimilating the American working to our Post Office system.

Disturbances.—The disturbances in telephone circuits created by the extension of electric railways have been severely felt in many parts of the United States. We have experienced the same in London, Liverpool, Leeds, and Blackpool. But owing to the prompt action taken by the telephone companies, especially in Boston, the area of disturbance has been much reduced, and the influence of electric railways on telephones has ceased to be a trouble. Of course this result is very much favoured by the rapid introduction of metallic circuits into cities ; but it has also been favoured by the prompt action of the railway companies themselves. They did all that they were asked to do, and that at once. In all cases the negative pole of the dynamo at the generating station is put to earth, and the return conductors have been enlarged. Extra copper wires have been buried between the rails, and heavier conductors have been put upon the poles. The return conductor is the largest size copper wire made—viz., No. 0. The rails have been bonded together and to this return conductor ; and in Boston the rails are welded electrically, which is very effective. I was unfortunately unable to see this electric welding in operation, for the transformer had broken down, and was in the shops under repair. I saw the whole apparatus, however. A special car is used for the plant, and the system adopted is extremely satisfactory. The electrolytic action of these disturbing currents has been noticed not only as affecting gas and water pipes, but also the lead coating of the telephone companies' cables. I have seen several specimens of lead pipes much pitted. I have reason to believe that the remedies adopted to cure disturbance will also put a stop to what might have become an element of great danger to underground cables.

Lightning Protection.—A very efficient system of lightning protection has been introduced upon the telephone system, not so much to protect the system from the effects of lightning, as from the effects of those powerful stray currents that enter a telephone circuit when accidental contacts occur between it and electric light and electric railway conductors. Such contacts have been frequent, owing to the prevalence of overhead systems, but they are diminishing now that conductors are placed underground. They have resulted in numerous accidents, and several telegraph and telephone offices have been set on fire and the apparatus destroyed. Every telephone circuit is now protected by a fuse, or cut-out—a fine wire of great resistance, which melts if traversed by a powerful current ; also by an air-space protector on the same principle as the lightning arresters we use, but having carbon plates instead of brass plates ; and, finally, by a small heat coil, which puts the current to earth in a very ingenious way when the stray currents exceed a certain strength. These three guards have been found quite effective. No accident has occurred where they have been used.

Rates.—The rates or rentals demanded from the various subscribers differ very much in the States. At Buffalo they charge a toll rate on each talk ; they do not demand an annual rental ; they simply demand a minimum amount of business per annum. This rate in Buffalo is 10 cents for five minutes' talk, and they have adopted a system of charging one-fifth of this rate for each extra minute beyond the five. The rate in San Francisco is a small annual rental for each installation, and five cents for each talk. A somewhat similar plan is in use at Milwaukee. But, with these three exceptions, the toll system has not found favour in the States, and at every other exchange an annual rental is demanded. The American Bell Telephone Company are now considering the advisability of limiting the time for talks to three minutes instead of five, of reducing the minimum toll in proportion, of making additional charges for each minute *pro rata*, and of considering a fraction of three minutes as equivalent to the whole time. I give, in tabular form, the rentals charged in 25 of the chief cities of the States (Table A).

The rates vary, and are, as will have been seen, very high ; but although the enterprise is in the hands of private companies, it must be noted that they have great difficulties to contend with. In a place like New York the rents and the cost of buildings is excessive. In one small exchange they pay no less than 7,000dol. a year rental for one floor. Taxes everywhere are enormous. Not only are they taxed by the State, but they are taxed by the municipalities. Way-leaves are excessive. In New York alone they have to pay to the

Newcastle	192,205	1,300	147·8

company controlling the underground conduits no less than 80,000dol. per annum way-leave—8dol. per renter for way-leave alone. The distances, too, that they have to carry their underground system in New York, in Philadelphia, and in other places are very considerable. They have been forced by municipal action to go underground. In the face of these restrictions no comparison between rentals in New York and those paid in this country can be made. The amount of the average rental in London scarcely exceeds £15 per annum. The average amount of rental throughout the country on our Post Office system is £9. 10s., but in New York subscribers have to pay up to £50 per annum. I have drawn up, with the assistance of the American Bell Telephone Company, a comparative statement showing the ratio between the subscribers and the population in 24 principal cities of the States. The details appear in Table B.

It will be seen how very much these places vary. In Providence, for instance, with a population of 132,146, we find one subscriber to each 45 persons; while in Philadelphia there is one to every 289 only. In 10 of the principal towns of our own country the results are as given in Table C.

The telephone in the United States is essential to the business man, and its price is compared with that of an office boy. Labour in the States is expensive, and an office boy costs more than a telephone subscription. The present generation in America has grown up with the telephone. It has become a factor of business, and absolutely essential to the transaction of that business. Its use has passed its climax; it has reached its normal stage. There is no touting for business; business comes. Every new office must have it. The working is excellent, and they are alive to the necessity of maintaining its efficiency at the very highest point. Education is complete, not only of the staff, but of the customer. The apparatus itself is being perfected. Uniformity of practice is being introduced under the operation of the paternal control at Boston, and the influence of technical education and of technical institutions is being felt everywhere. I find a group of highly-educated, clever young electricians being engaged and encouraged by the telephone companies. New blood is being introduced, and great zeal and activity is shown.

III. THE ELECTRICAL CONGRESS.

Two congresses were held at Chicago—the one, a general one, to which all electricians were invited; and the other, called "The Chamber of Delegates," to which nominees from the different Governments were sent. The latter was the more important of the two, but each secured considerable attention, and they were distinctly great successes. The following extract from an American technical journal very fairly summarises the results:

"*The Chicago Congress.*—The much-talked-of international electrical congress is now a thing of the past. Its records may be briefly summarised by saying that the attendance was good; that it was truly international; that there were just about enough papers; that some good work was done; that the social features were enjoyable; and that, while the general management left much to be desired, the congress itself was a success—not quite as grand a success as we should like to have seen, but, nevertheless, a success. Among the papers read were a few which created unusual interest, and some which will doubtless become standards of reference. The papers and discussions were of such a character that the published volumes of the *Proceedings* will be interesting reading, and will become a book of reference. The foreign attendance was such that the congress became truly an international one. Among the foreign countries represented England took the lead in numbers, and especially in papers read, and in the discussions. Germany and France came next. That it was an international assembly was shown by the fact that the French language was freely used in papers and discussions, the only reason why German was not used being that educated natives of that country almost always understand and speak English. Thanks to a few energetic, experienced, and willing members and exhibitors, the social features were not entirely omitted. The social events that did take place were enjoyable, and will be long remembered by those who took part."

The congress met on August 21, at least 500 being present. Prof. von Helmholtz was appointed hon. president; Prof. Elisha Gray, chairman. Each principal European country had a vice-president, and I had the honour of being selected to represent England. The congress was divided into three sections: (*a*) pure theory; (*b*) theory and practice; (*c*) pure practice. Some excellent papers were read, and good discussions ensued. The most prominent subjects dealt with were the transmission of power to great distances, and general preference was shown for alternating-current systems. The work being done at Niagara excited general interest, and some of us visited these works afterwards, with great profit and pleasure. Prof. Ayrton read a very able paper on the variation of arc lamps, so much used in America; while much interest was created by the reading of a paper by Prof. Silvanus Thompson on "Ocean Telephony," a possibility in the future. My paper on "Signalling Through

Digitized by Google

Space" also created much interest. Perhaps the most useful result of the congress was the bringing together of such an international mixture of electricians, making friendships, allaying jealousies, and breaking down national prejudices. Electricity is the only branch of science which has but one language, and it is now quite cosmical in its character. Congresses do infinite good in promoting friendliness among nations.

Chamber of Delegates.—The object of this meeting was really to consummate the work done by the British Association and by the Board of Trade, and to secure the official sanction of the United States Government to the units selected and adopted in England. This was done, and the report of the Chamber gives international support to the proposed legalisation of the ohm, volt, farad, ampere, watt, and joule, as defined by the committee of the Board of Trade. There is no doubt that all European Governments will now accept these decisions. A new unit was adopted—viz., the "henry," a unit of induction, which was sometimes called the "quadrant," as defined in Paris in 1889, and sometimes the "secohm," as proposed in England. The acceptance of the name "henry" pleased the Americans very much, for their nationality has hitherto been unrepresented among the celebrated electricians whose names have been applied to the standards of electrical measurements. Germany, Italy, France, were represented by Ohm, Volta, Coulomb, and Ampère; while England absorbed no less than three—viz., Faraday, Watt, and Joule. America has now her Henry, and is satisfied.

The following is the official report of the proceedings: "*Resolved*,—That the several Governments represented by the delegates of this International Congress of Electricians be, and they are hereby, recommended to formally adopt as legal units of electrical measure the following: As a unit of resistance, the *international ohm*, which is based upon the ohm equal to 10^9 units of resistance of the C.G.S. system of electromagnetic units, and is represented by the resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice 14·4521 grammes in mass, of a constant cross-sectional area, and of the length of 106·3 centimetres. As a unit of current, the *international ampere*, which is one-tenth of the unit of current of the C.G.S. system of electromagnetic units, and which is represented sufficiently well for practical use by the unvarying current which, when passed through a solution of nitrate of silver in water, and in accordance with accompanying specifications, deposits silver at the rate of 0·001118 of a gramme per second. As a unit of E.M.F., the *international volt*, which is the E.M.F. that, steadily applied to a conductor whose resistance is one international ohm, will produce a current of one international ampere, and which is represented sufficiently well for practical use by $\frac{1000}{1434}$ of the E.M.F. between the poles or electrodes of the voltaic cell known as Clark's cell at a temperature of 15deg. C., and prepared in the manner described in the accompanying specification. As a unity of quantity, the *international coulomb*, which is the quantity of electricity transferred by a current of one international ampere in one second. As a unit of capacity, the *international farad*, which is the capacity of a condenser charged to a potential of one international volt by one international coulomb of electricity. As a unit of work, the *joule*, which is equal to 10^7 units of work in the C.G.S. system, and which is represented sufficiently well for practical use by the energy expended in one second by an international ampere in an international ohm. As a unit of power, the *watt*, which is equal to 10^7 units of power in the C.G.S. system, and which is represented sufficiently well for practical use by the work done at the rate of one joule per second. As the unit of induction, the *henry*, which is the induction in a circuit when the E.M.F. induced in this circuit is one international volt, while the inducing current varies at the rate of one ampere per second. The Chamber also voted that it was not wise to adopt or recommend a standard of light at the present time."

An attempt was made to introduce other units, but the feeling is pretty strong that language-framing electricians must rest on their oars for a time. New ideas and new measurements must have new terms and new names, but the general public must become more accustomed to the new language already invented before proceeding to manufacture more novelties in phraseology. The new terms are even now very difficult to explain, and still more difficult to understand. Moreover, electricians themselves are not sufficiently unanimous either as to the necessity or upon the accuracy of the definitions of the new conditions, and therefore they can afford to wait for a final settlement for another congress some years hence—perhaps in Paris in 1900.

IV. The Exhibition.

Nothing grander in design or more beautiful in execution has ever been seen in this world than the group of buildings situated in Jackson Park, Chicago, and called the "World's Fair." It is a great misfortune that the world did not appreciate, nor respond to, the ambitious views of the conveners of this fair. Their conception was magnificent. Their architects, if they did not originate the plans, certainly rose to the occasion. Their builders realised their views. Every possible convenience and accommodation was provided for exhibitors, but the response was poor, and the internal management of the whole business, owing to inexperience and perhaps overweening confidence, was indifferent. The success of the undertaking hovered for some time over failure; but fine weather, patriotism, novelty, real beauty, and cheap fares at last attracted crowds, which, numbering about 200,000 a day, have converted what looked like a disaster into a well-deserved success. I have not much to say of the exhibition as an exhibition. It was very like its predecessors. It did not attract me, for, having taken part in nearly every exhibition for the last 15 years, I am sick of exhibitions. I devoted much attention to the electricity building, and observed there several novelties, some of which I have referred to in other parts of this report. Gray's telautograph attracted much attention. It is an improvement on Cowper's writing telegraph. It reproduces the motion of a pen, so that while you are writing in London a phantom hand seems to guide the pen and reproduce your own writing in Nottingham. You can see the pen move, dot the i's, and cross the t's. It makes corrections and erasures. It works well, but very weirdly. My writing and signature were clearly reproduced at the very first trial. But it is immature for practical trial at present. It has not reached its final stage. It is being improved every day. It is very complicated in construction, and it requires four wires to work it. The Western Union Company in Chicago have established a circuit between their head office and stores department, and are giving it a good test. The French and German Administrations sent admirable and extensive displays of their historical and working apparatus, with a very large staff of men to attend to them, but I am pleased to say that our exhibit proved much more attractive and interesting. It was better arranged and more complete; and our one solitary assistant, Mr. J. Chapman, won golden opinions by the admirable way in which he attended to his duties, and by the excellent verbal explanations he gave of our show. The United States of America made no historic exhibit, but the Western Union Company showed many relics and examples of Morse's early work. The American public were surprised to find how much we in England had anticipated their work. Morse's first message, "What has God wrought?" was sent only in 1844. Our history commenced in 1837. Our jubilee was celebrated in 1887. Theirs is to be celebrated this year. An exhibit that attracted much attention was a door which opened before you as you approached it, and closed behind you as you receded from it. This was done by a small electric motor which was set in motion when you stepped on a mat, and released when you passed through the door. It was worked with the same current that would light an incandescent lamp. Both on entering the harbour of New York, and on going by steamer from Chicago to the World's Fair, channels for the passage of the steamship were clearly marked out at night by incandescent lamps fixed on spar buoys, and lighted up in series. There was shown an electric selector of great merit and some originality. It was a plan by which any particular railway station could be selected and called, any particular signal cleared or put to danger, any office on a long circuit with several intermediate instruments selected and secured, any subscriber on a combination telephone circuit—that is, on a single circuit upon which several renters are fixed—could be called and isolated from the rest. All the great manufacturers in the United States made large exhibits of their wares. The American Bell Telephone Company, the Western Electric Manufacturing Company, the General Electric Company, the Westinghouse Company, and the Standard Electric Company had splendid shows but few novelties. Their novelties have already been referred to, either under electric lighting or electric railway. Electric lifts were on exhibition and in use. They worked very well, indeed, and are rapidly coming into general use in the States. The new postal telegraph building in New York is being fitted with several of these lifts, which are going to be worked very quickly indeed (600ft. a minute). They are being installed by the Sprague Company. Electric welding was shown in full operation, and attracted much attention. Power was transmitted all over the place by currents, and whole exhibits were shown in motion by means of electric motors. Along the machinery hall, 1,400ft. in length, an electric crane, 75ft. span, travelled, and formed an admirable point of observation for those who were allowed to travel on it. It was used in the preparation of the exhibition to lift and fix all the machinery. It lifts and moves 40 tons. It is worked by five motors. Its weight is 58 tons, and its speed was excellent. There were large exhibits of every class of cable manufactured in the States—Waring, okonite, kerite, Patterson, dry-core, etc.; and Felten and Guilleaume had in the German section a fine show of their own make. Sections of streets were shown, with pavement, manhole, conduits, joints, and everything complete. England is the home of the alternator, but it has now taken firm root in America. In 1884 there was not a single one to be found in Philadelphia. Now they are everywhere, and alternate currents are being studied and developed in a way

Digitized by Google

that is completely putting our experimentalists in the back row.

The paucity of real novelties, or of what are commonly known as "Yankee notions," was very marked. The necessity for such things—that is, the scarcity of labour—has apparently disappeared, and with its parent the child has languished. Moore's spark interrupter—an automatic vibrating armature in a vacuum tube, by which incandescent lamps can be turned up or down without wasting energy—was described at a meeting of the electrical engineers at New York, but I did not see it at the World's Fair. The distinguishing feature of the Chicago World's Fair was not alone its uniqueness, but its grandeur and its magnificence. It was not an exhibition of goods and manufactures in the Old World sense. No one seemed to care two straws for the mere trade exhibition *per se*; he admired the beautiful buildings, the waterways, the external attractions, and, above all, the congeries of people that assembled from all quarters of that great continent in such multitudes. The distinguishing feature of American engineering is the great scale on which it is carried out, and the rapidity of its adoption. An electric railway from Chicago to St. Louis, 250 miles long, is not a difficult engineering feat, for the country is level, but it is novel for the fact that it is projected to travel at the rate of 100 miles an hour. There were some things in the exhibition that were extremely interesting. The first was a complete reproduction of an ancient Viking's warship—an open boat, that would excite fear and trembling even in crossing the Channel, but of a type that probably crossed the Atlantic long before the famous fleet of Columbus. These vessels—the "Santa Maria," "Pinta," and "Nina"—were also reproduced in all their dimensions, and in all their colours and fittings. The contrast between these relics of the past and the modern warship built alongside the home of the British Commission, Victoria House, was, to my mind, more suggestive than all the innumerable wares and appliances so freely exposed in the vast extent of covered area. One interesting building was a kind of baby cloakroom, where mothers could book their babies for the day, and who were there carefully tended, nursed, amused, and fed for a very small charge. Each mother received a small brass check, which was her guarantee for the safe custody of her little beauty.

V. Electric Lighting.

Electric lighting has not generally made the rapid progress during the past nine years in the States that was expected from its great rate of growth during the previous four years. Wild speculation, hasty construction, fatal accidents, and frequent failures have reacted on steady progress. At the same time the advance has been very great, principally in public street lighting. All towns and villages in all parts of the country, however small and isolated, or however distant, seem to have adopted public arc lighting. Arc lamps are found suspended over the roadways in a very rough-and-ready way, sometimes from stretched wires, sometimes from long-balanced levers, but always effective. The arc lamp-posts are generally of timber, like telegraph poles; occasionally squared timber, as in Broadway, New York; and sometimes plain and neat iron poles, made of differing sections of iron pipes, but rarely so heavy, massive, artistic, and expensive, as in England. Clear glass globes appear to be almost universal in use. It is quite rare to see frosted glass or opaline shades. The principal novelty introduced has been the use of flat carbons or oval or elliptic section, to increase the duration of the light. They are 310mm. long; the major axis is 25mm., and the minor 11mm. The ordinary arc lamps burns as a rule only eight hours, but this flat carbon doubles its life. Moreover, the flat carbon is found very advantageous and useful with alternating-current systems, on which arc lamps as a rule work badly. The standard current used is 10 amperes, and the energy expended varies from 400 to 500 watts. The lamps burn very steadily as a rule, and give a light of about 800 candles at the angle of maximum intensity. An excellent self-regulating alternator for public arc lighting, designed by Stanley, was exhibited by the Westinghouse Company. It maintained its current quite constant, however much the number of the lamps was varied, between 0 and 24. Any number could be turned on or off without the least difference being detected in the current on the light. The favourite arc dynamo in the States is said to be that supplied by the Standard Electric Light Company. There was a large exhibit—six machines—of this type in the exhibition. The largest size worked with 6,550 volts, and maintained 120 arcs in series. It is fitted with a very effective and rapid working automatic governor, regulating the range of the brushes, so that as lamps were turned off the current was maintained constant and the voltage changed. Six seconds only were needed to regulate the brushes from a load of one lamp to 50 lamps. Arc lighting is used very much for shop-lighting, not only in the interior for general illumination, but for advertising and attractive purposes outside. Indeed, many of the streets of the principal cities—especially New York and Chicago—are more brilliantly lighted by the shopkeepers than by the municipalities. In fact, in many cities there are many more arcs supplied for private than for public purposes.

Incandescent Lighting.—Incandescent lamps are, within my observation, invariably used in telegraph offices, post offices, telephone exchange rooms, hotels, and in many railway stations. The electric light is more general in such public places than with us. I did not visit a single place that was not so fitted, and with incandescent lamps. In private houses it is much used, but not so generally as with us. In Chicago the residential lighting is only 33 per cent of the total. In all large cities there are immense blocks of buildings fitted with lifts and used as offices. In all cases they were lighted by their own isolated plants. One of the most striking features of a bird's-eye view from some lofty spot of a great city, like New York or Chicago, is the white, fleecy, wool-like jets of vapour that float gracefully away from the top of every large building. They are to be reckoned by the hundred, and every one means steam plant working lifts and electric light. The Western Union Company at New York and Chicago have their own steam plants. When I visited Chicago in 1884 no central electric lighting station had been built, and no current was supplied. Now, a capital of 2,233,000dol. earns an income of 320,000dol. yearly. The incandescent lamps (16 c.p.) fixed are 136,409; arc lamps fixed, 4,376; motors supplied—total horse-power, 3,612; and this is equivalent to 430,000 10-c.p. lamps fixed, or such lamps as we reckon with in England. The maximum load is 50 per cent. of these lamps alight at one time, which accords with our experience in England. The price works out at 7½d. per kilowatt-hour, or supply unit, and this includes the cost of the renewal of the lamp. The cost of production works out at 3½d. per unit. The cost of the production of electric energy in the States differs, therefore, very little from that experienced here. It is steadily on the decrease. As the load increases, as the daily supply lengthens in duration, as the generators increase in size, so will the cost diminish; and how long it will fall no one can predicate. Anyway, it will certainly far exceed in economy the production of gas. The price of lamps to the undertaker—that is, to the electric light company—is 1s. 4d.; the life of the lamp is 600 hours. A 16-c.p. lamp takes 0·45 ampere and 110 volts. It is, therefore, a 50-watt lamp, and a better one than we get at present in England. The screw socket appears to be in universal use. I wish it were so here. There are three central stations in Chicago. A new station is being built alongside the water in Harrison-street with a capacity for utilising 20,000 h.p., where every modern appliance for cheap fuel, automatic feeding, condensing, and economising will be used. The south side central station is worked by natural gas, which is brought in pipes 100 miles long from Indiana. It is very cheap compared with coal. I found in use in Chicago a system of raising the voltage on the feeders when the pressure falls, owing to the increase of load, by switching in motor dynamos. They have given the name of "boosters" to these instruments. A somewhat similar system has been applied at the Midland Railway, Derby. The exhibition and its surroundings were, of course, brilliantly and entirely lighted by electricity.

(To be continued.)

BLACKPOOL.

Report of the electrical engineer to the chairman and members of the Tramway Committee:

Gentlemen,—Agreeably with the instructions given me at the last meeting of the committee, I now beg to hand you a report giving my opinion as to the present condition of and the causes of the recent trouble with the Corporation's electrical tramway plant. I would respectfully point out that this is now placing on record fully, for the first time, the suggestions and reports I have at various times made verbally to the committee.

Engines and Boilers.—These are in good average condition, only the governors requiring renewal. The valves have been adjusted during the past year, and it is my opinion that there are many years' work yet to be got out of these engines.

Belting and Shafting.—The committee will remember that the engines drive on to a countershafting by means of ropes, and from the countershafting to the dynamos by means of two link leather belts. It is in this important connection that trouble has been given frequently. The ropes on one engine have had to be replaced, the old ones being worn out. Before replacing them it was occasionally necessary to stop one engine and start the other when ropes broke. These stoppages were on an average three to five minutes in duration. On September 9, 1892 (the first day on which the Corporation controlled these tramways), the main belt on No. 1 dynamo broke. Since that date to about August, 1893, one or other of the belts have given trouble on an average every 10 days. These did not, however, cause stoppages of the cars, one dynamo being able to do double duty until the necessary repairs were carried out. It was, however, in the early part of September last that the more serious trouble with the belts began, and although on August 24 I reported to the committee that the belts were rotten and running under protest,

Digitized by Google

the difficulties were still further accentuated later. It may be well if I here say that had the load on the dynamos been regular, even though heavy, the belts and all the parts would have borne the strain safely. It was owing to the excessive and irregular strains that the troubles arose, and that the care of these belts became a dangerous occupation. The hole in the roof of the engine-room still stands as a testimony to one of the many breakages. This point is further discussed when dealing with the question of the collector and channel.

Dynamos.—The dynamos are in a condition equal to that in which they were handed over to the Corporation, with the exception of the commutator of one machine, which is worn out. No stoppage has been caused by this. Trouble, however, has been experienced owing to the breaking of armature connections. This is due almost entirely to the heavy strains arising from the "short-circuits" and "cut-outs," also discussed under the heading of the collector and channel.

Motors and Gearing.—The motors have run well, with one or two exceptions, considering their condition when handed over to the Corporation. The field-magnet windings have had to be renewed in some cases, and repaired in almost all. In one or two cases wires had been ripped bodily off the framework of the motor by the steel end of the collector rising and catching the motor on a "break away" happening at a narrow part of the channel. When it is remembered that the disconnection of one wire will stop a car, the importance of this is readily seen. The wiring in the cars has given considerable trouble and in most cases has been renewed. The old joints had been made with salts as a flux, and even though the action was slow it was certain, and at the end of seven to 7½ years all the joints so made became useless. This is interesting as giving the life of a badly-made joint, but as an experience on taking over the old company's system it is disheartening.

Centre Channel and Collector.—In discussing the question of the centre channel, I would venture to invite careful attention to its construction, particularly with reference to the cover rails or troughing and insulators with the method of the attachment to the conductor. The cover rails being fixed, it becomes an impossibility to examine the connections and insulators frequently. Nor can the whole of the insulators be cleaned more than once a year, and even on this occasion they cannot be freely handled. The freedom with which dirt enters the channel is well known. In removing it, it is impossible to avoid leaving some amount round the insulators. In the course of a month or two this becomes a serious consideration, and at the end of 12 months the leakage for the first few hours of the day is sufficient to drive 10 to 20 cars. Then the cover rails expand and contract with varying temperatures, supporting chairs in many instances break, and the slot, which should be ½in., diminishes to three-eighths of an inch or even less. It should be borne in mind that through this slot has to pass the current-carrying conductor to the motors, and that this must be well insulated. To make an efficient collector for this system to pass through a ⅜in. slot is impossible. By an efficient collector I mean one that will run a week without causing any trouble in any kind of weather. Our record during the past year has shown days on which as many as 24 to 30 collectors have been sent into the shed for repairs. The evil effects of the narrow channel and bad insulation are not seen alone in the frequent "breaking away" of the collectors, but react seriously into the engine-room. On the occasion of a collector giving way or a "break away" occurring, the whole of the current from both dynamos and the whole of the engine power is called for in a moment. The strain rises in less than half a second from 2 h.p to 3 h.p. driving the car to 75 or 80, all of which is being spent in burning up the collector or channel. The engines may stand it, but the belts break, and if the belts do not break the dynamos suffer. It is my firm conviction that if the channel construction had originally been such as to admit of a wider slot with more perfect insulators and collectors, the trouble we are at present experiencing would never have occurred. And if the committee is desirous of making the present system run, the only manner by which, in my opinion, it can be done, is by attention to these points.

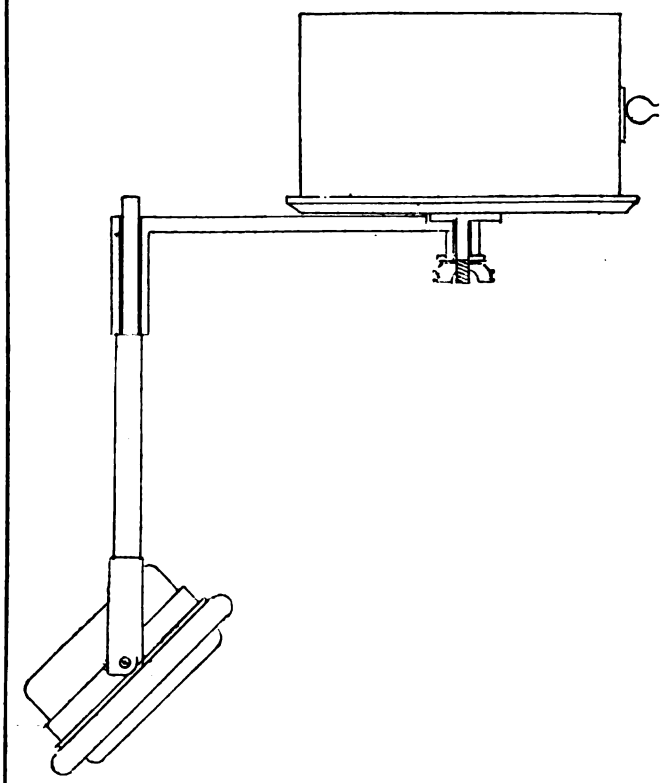
It would not be justice to the staff, who have had to bear the brunt of these troubles, if I did not here record how well they have striven to meet the difficulties as they arose. I am convinced that had not they in my department, and the traffic manager with his staff in his, done their level utmost up to, and more especially since August last, the complaints would have been, if not more frequent, at least more justifiable.

JOHN HESKETH, Borough Electrical Engineer.

P.S.—It is well to point out that if the committee intend to run electrically during the coming season, immediate steps must be taken to put the road in order, and to obtain two new cars.

TELEPHONE RECEIVERS.

Mr. Rickinson has designed a modification of the ordinary rigid telephone receiver holder which he thinks an improvement. No doubt it is often desirable for the listener to have both hands at liberty. Another improvement is the addition of an indiarubber ring to the earpiece of the receiver, termed a pneumatic cushion, its office being to fit closely around the ear and cut off all extraneous sounds, as well as to concentrate the sounds of the telephone itself to the ear for which they are created.



The accompanying illustration shows the arrangement adopted. Besides the joints, as shown, the receiver is swivelled, and can be adjusted for convenience through a short range before being brought up by stops. One advantage of this apparatus is that it keeps the user of the instrument from putting his mouth too close to the transmitter, a position which, added to loud talking, frequently causes indistinct transmission and a rattle in the receiver, which, to say the least, is unpleasant.

COMPANIES' MEETINGS.

CROMPTON AND CO., LIMITED.

An extraordinary general meeting of this Company was held on Tuesday at the Cannon-street Hotel, under the presidency of Viscount Emlyn.

The **Chairman** moved that the directors be authorised to borrow any sum or sums of money upon such terms as they might deem fit, provided that the amount borrowed did not exceed, without the further sanction of a general meeting, £100,000. He said the balance-sheet up to March, 1893, showed that the Company had borrowed from their bankers £18,000. Since that time, with the view of extending their business and taking up contracts, they had found themselves obliged from time to time to increase that amount. The taking up of large contracts meant increased expenditure, and if they could raise an additional £100,000 in debentures, the Company would be in a far stronger position to deal with the business in hand, and that which they felt sure was coming to them. Their object was to displace the existing £50,000 of 5 per cent. debentures to pay off the whole of the bank loans, and to deal with any trade creditors. The debtors of the Company practically represented twice as much as the trade creditors. The issue would only mean an increase of £500 or £600 a year in interest, and this would be more than counterbalanced by the advantages obtained in being able to pay cash for materials, etc. He had no doubt that the directors would be able to raise the whole £100,000 on moderate terms.

Mr. R. E. Crompton seconded the motion.

Mr. Kitchen asked what amount of the Company's assets were represented by shares in other companies; if it was intended to pay the interim dividend on the preference shares in the event of £100,000 being raised; and also if the bank had made any objection to the continuance of the somewhat large loan which the Company had had.

The **Chairman**, in reply, said the shares in other companies amounted to £12,004 in March last, and in September to £12,375. The directors had every hope that they would be able to declare an interim dividend of 2s 6d. a share within a reasonable time, but they could not pledge themselves to any particular date. There was a limit beyond which the bankers would not be willing to let them go, but hitherto they had met them very freely.

Digitized by Google

Mr. Kitchen said the directors had first announced that they could pay no more dividend, and then they wanted more money. There might possibly be other reasons for the issue of debentures, and those reasons were what he would venture to call unsound finance. There was a suspicion in the minds of shareholders that the Company was taking large and valuable contracts and accepting a portion of the payment in cash and the remainder in shares. He had seen two companies brought to the verge of bankruptcy by adopting that course, and if this large issue of debentures was to be used in accepting contracts on such terms, he hoped the shareholders would withhold their sanction to the proposed issue. He asked what amount the Company held in the Hove Electric Electric Lighting Company.

The **Chairman** said it was not the case that the directors had announced that they could pay no dividend. What they said was that "Notwithstanding the late serious depression in trade the profits of the Company, during the six months ending September 30 last, were sufficient to justify the directors in declaring an interim dividend; but owing to the necessities of the business in carrying out the various large contracts in hand, the directors had hesitated about doing this until the arrangements for further capital by the present issue of debentures were completed." It had always been his desire that contracts should be made on a business footing—that was to say, that the terms should, as far as possible, be cash, and the directors were now practically carrying out the system suggested by Mr. Kitchen. They had taken £2,000 in shares in the Hove Company really to assist in its formation, and they had a contract at Hove for £35,000, the whole of which was payable in cash. It was with the view of carrying out the contracts in the manner suggested that the directors proposed to issue debentures.

The resolution was then put and carried.

CITY AND SOUTH LONDON RAILWAY COMPANY.

The nineteenth ordinary general meeting was held yesterday (Thursday), at Winchester House, Old Broad-street, E.C., Mr. C. Grey Mott (chairman) presiding.

The **Chairman**, in moving the adoption of the report and accounts, said that he was glad to say that during the past half-year they had again carried the whole of the large number of passengers with absolute safety, and almost with punctuality. As regarded the number of passengers carried, there had been a slight check in the regular increase which the Company had had every half-year. The shareholders would notice from the statement appended to the report that, as compared with the corresponding period of last year, there had been a decrease of 24,251 passengers, but that was exclusive of season-ticket holders. The latter showed an increase of 59, and practically there was an increase on the half-year in the number of passengers carried. The Company would have done better had it not been for special causes. Fine weather morning and evening, as he had pointed out on previous occasions, was always against the traffic on this line, and during the greater part of the half-year exceptionally fine weather prevailed. Then, again, they were confronted with the closing of Kennington Oval for over three months, and the football matches there formed a considerable source of revenue to the Company. Of course, they had lost that traffic, and were continuing to do so for a month or two. When the Oval was again open they hoped to get an improved traffic. The Company had also suffered, in common with other railway companies, from the general depression—not in the same way as if they had goods traffic, but that kind of depression was always felt even on passenger lines solely, and was shown by the large decrease in passenger traffic all over the kingdom. The Company had not been idle during the half-year. The new sidings at Stockwell had been brought into use, and they had been able to give a better service, and decrease the overcrowding in the morning and evening. The result had been an increased mileage of about 10,000 miles more than in the corresponding half of last year. They had also introduced additional intermediate signals, which had also contributed towards improving the service. The Company had been at work at the upper part of King William-street Station, and in the course of the present month that would be finished and opened. It would quite transform the appearance of the station, make it more attractive, and would, it was hoped, tend to increase the traffic on the line It was hoped that the expenditure would be recouped by increased rates that they would get from the left luggage and parcel offices, and other things. A large quantity of debentures came due before the end of the year, and they had paid off some £32,200 of the terminable debentures, and part of those had already been replaced by 4 per cent. debenture stock. The Company had borrowed part of the money to pay them off, but as they are placed on the market that loan would soon be got rid of. The Bill for extensions had passed this session. The chairman then referred to the capital and revenue accounts. With regard to the working expenses, they amounted to 64·6 per cent. as against 67·9 per cent., and if the cost of working the lifts was deducted, came out at about 55 per cent., which was less than most of the railways in the country. The receipts per train mile were exactly the same as last year—namely, 2s. 0½d.; the expenditure 1s. 4d as against 1s. 5½d.; locomotive expenses were 6·22d., as compared with 7·1d. last year, showing a slight reduction. If they deducted the cost of transport of coal, and which other companies had not to pay, the figure would be about 5d. per train mile, which was about half what it cost on the steam lines. Of course the Company's trains were lighter. The receipts per passenger amounted to 1·65d. as against 1·60d., being a slight increase. The question had been raised as to whether the directors should not have taken something further out of the balance brought forward and paid another ⅛ per cent. dividend. Well, the directors thought it would add to the general value of the property of the company that they should show the greatest prudence in this matter, and rather than take from the balance brought forward, they should add a slight amount to it. The line had been open for three years, and he thought they had shown that the electrical system was specially suitable for this class of traffic. He considered it pretty clear now that electricity certainly for metropolitan railways was going to be a cheaper method than that of steam. The position of the Company was very solid. It only needed an increase in the dividends on the ordinary shares to make it rank as one of the first railways in the kingdom. Their securities, preference shares, and debentures, were as solid as anyone could get in these days, and they ought to command as high a price as any railway in the country. The question of carrying out the Islington extension was a matter which they were carefully considering, and were not disposed to move until they were in the position of feeling that there would be no possible diminution of the dividend during the time that the works were being executed But the moment that the extension was carried out and opened, he had not the slightest hesitation that the dividend would advance rapidly. The extra cost of working would be very small, and the receipts would be very large. At the same time they must proceed with the matter with the greatest precaution, and they had therefore not brought any scheme before them on that occasion, and would not do so until they could present a case which he thought they would feel was unanswerable. He then moved the adoption of the report and accounts.

Mr. Edwin Tate had pleasure in seconding the motion.

Some remarks were then made by **Mr. Drake**, who, whilst being thankful for small mercies, said that the management had not made the line a commercial success.

Mr. Blackwood followed, criticising the small dividend and the prospects set forth in the Company's prospectus in regard to a 12 per cent. dividend.

The **Chairman**, in reply, said that it had always been complained that he had always refrained from putting more *couleur de rose* in his statements at the various meetings. The prospectus was issued in the dark as to what the circumstances of the line would be at this time; deductions had simply been withdrawn from existing facts. He did not despair that if the policy they were adopting or intending to adopt was carried out, the day might come when even 12 per cent. might be realised, but it was a difficult operation to perform. Arrangements were proposed in regard to securing some of the traffic passing over London Bridge by the erection of a station on the southern side of the river, and the fares were being judiciously increased. The Chairman then put the motion, which was unanimously adopted.

The dividends recommended were adopted. Messrs Sampson Hanbury and S. Barclay Heward were re-elected directors, and Mr. J. Oliver was reappointed auditor. The passing of a vote of thanks to the directors concluded the proceedings.

ANGLO-AMERICAN TELEGRAPH COMPANY.

The ordinary general meeting of this Company was held last week at Winchester House, Old Broad-street, the Marquis of Tweeddale presiding.

The **Chairman**, in moving the adoption of the report, said that the amount available for dividend was less this year by £13,893. Traffic receipts showed a falling off of £8,493, and this year there was a slight increase in the expenses, amounting to £622. The reduction of receipts was entirely due to dull trade. The failure of the expeditions to repair the two cables had added very much to the wrong side of the account, but the failures were due to the weather. With regard to the condition of the two cables he was glad to say that the 1874 cable was found to be in a good condition, and no doubt it would be easily repairable. The Brest cable, on the other hand, was by no means in the same condition. They had not formed any opinion as to what steps should be taken to put it in a proper condition, but they would have to consult the best of experts upon the matter, and act accordingly Both the Western Union cables were in good order. It was quite necessary that they should be in a position to provide the means of carrying their large traffic efficiently in the future, and after careful consideration they had decided to lay a new cable of a new type, and possessing superior carrying capacity. The cost of the cable would be £450,000, which might be regarded as moderate, being cheaper than any cable laid in the Atlantic, having regard to its carrying power and quality—it would carry about 45 words a minute. The expenditure upon that cable would materially reduce the renewal fund, which, however, it must be borne in mind was established for the purpose of doing what they were going to do. He would have been glad if they could have delayed the laying of the cable for some time, but they had come to the conclusion that it would be imprudent to do so beyond this year. It might be asked how did they intend to fill the void in the renewal fund caused by the large expenditure. He could not give any definite statement as to the life of a cable, and he, therefore, thought the proper mode of dealing with it was to add to the fund each half-year as circumstances permitted. Every half-year they must add a substantial sum to the reserve. He did not think they could be expected to recommend the laying by of a less sum than £40,000 or £50,000, inclusive of the interest on the reserve

Digitized by Google

fund, something like £16,000. With regard to the French law-suit, he was glad to say that it would be settled in the course of the next month, at any rate, as far as that particular court was concerned.

Mr. Bevan seconded the motion, which, after some discussion, was adopted, and the dividends having been declared as recommended, the business was concluded.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY.

Directors: Eustace J. A. Balfour, Esq., chairman; H. Woodburn Kirby, Esq., vice-chairman; Gerald W. Balfour, Esq., M.P.; Latimer Clark, Esq., F.R.S.; Sir John H. Morris, K.C.S.I. General manager and secretary, Frederic J. Walker. Chief engineer, S. T. Dobson, A.M.I.C.E., M.I.E.E.

Report of the directors and abstract of accounts for the year ending December 31, 1893.

The directors beg leave to submit their annual report for 1893, the accounts accompanying the same being duly certified by the Company's auditors. These accounts have also been before the Board of Trade. The judgment in the action brought against the Company by Dr. John Hopkinson in connection with the infringement of his three-wire patent was only delivered on January 14, 1893, the day of the issue of the last annual report. The Company, in resisting Dr. Hopkinson's claim, were acting in conjunction with the London low-tension supply companies generally. The directors, after fully considering the effect of this judgment in consultation with their experts, deemed it better to compromise with Dr. Hopkinson rather than run the risk involved in further litigation. They are happy to report that a compromise was effected on very favourable terms, under which the plaintiff waived his costs and granted a license to the Company for the remaining term of the patent and any extension thereof. The cost of the license and the proportion of law expenses attributable to this Company, amounting together to £4,446. 8s. 9d., is considerably less than the additional sum that would have been expended on the mains had the Hopkinson system not been adopted. This expenditure has therefore been carried to capital account. During the year the Company has also been involved in litigation with certain holders of founders' shares, who claimed a moiety of the £2,000 forming the basis of the "redemption fund." This they successfully ligitated, and one-half of the £2,000 has been divided amongst them. The other thousand pounds has been carried to the "ordinary shareholders' undivided profit account." The decision of the Court prohibits the directors from following a policy which all four judges who heard the case approved, and which was directed to conserving the assets of the undertaking for the benefit of the shareholders generally. It is obvious that the ordinary shareholders should not be asked to build up a redemption fund in which it is possible that the founders might ultimately participate to the extent of 25 per cent. under Clause 122 of the articles of association of the Company. An action brought by the Windham Club was settled upon terms satisfactory to the Company. Having regard to the increasing demand for current, and for other reasons, it has been deemed necessary to arrange for an enlargement of the Carnaby-street central station, and in view of this the Company has purchased land on the north and south sides of that station. Plans for this extension are being got out. The directors are considering the issue of debenture stock under the Company's borrowing powers to provide the necessary capital. At the commencement of the year under review, the company which possesses concurrent powers in the parliamentary area allotted to this undertaking started a system of competition which your directors regret to report led to a reduction of price of supply, with a consequent decrease of income. This reduction the directors resisted as long as they could prudently do so, but it became clear in the spring of the year that unless they were prepared to lower the cost of supply they would lose the business that has been built up during the last few years. It is an encouraging feature, however, that the number of the Company's customers has largely increased. From this and other factors working in the Company's interest, the directors believe they may safely hazard the opinion that the diminution of dividend is temporary only, and that in future years the income of the Company will justify a larger return to the shareholders. The coal crisis which has affected so many classes of trade detrimentally has not, your directors are happy to report, affected this Company, for the reason that they had previously secured a contract continuing until the end of March next. They are also pleased to report that the cost of producing the current has not been increased, but, on the contrary, is something below the figures of last year. The shareholders will observe that the securities representing the "capital reserve fund" have been altered. This was done to enable the Company to enjoy a larger rate of interest than they could under the original investment. It will also be noted that although the "redemption fund" no longer exists, the securities representing it have not been sold. The amount is invested in bank stock, which has depreciated, and the directors being of opinion that such depreciation is only temporary, they do not feel it desirable to realise it at existing quotations. The year through which we have last passed has been one which has given your directors much extra work and considerable anxiety. And they have, as in the past, done all in their power to protect and conserve the interests of the Company, and they trust that the fruits of these efforts may show themselves in future years. The net earnings of the Company during the past year have amounted to £10,552. 2s. 7d. Of this sum, £3,500 was distributed in July last in payment of an interim dividend at the rate of 7 per cent. per annum for the half-year ending June 30, 1893, on the preference shares. The balance, £7,052. 2s. 7d., together with the undivided profit of £63. 16s. 2d. from last year's account, and the £1,000 carried from the "redemption fund account" to "ordinary shareholders' undivided profit account" leaves £8,115. 18s. 9d. now to be dealt with. The directors propose to divide this amount as follows:

(A) By payment of a dividend at the rate of 7 per cent. per annum on the preference shares for the second half of the year	£3,500	0	0
(B) By payment of a dividend at the rate of 4½ per cent. per annum for the year on the ordinary shares	4,495	10	0
(C) Amount to be carried forward to "ordinary shareholders' undivided profit account"	115	19	7
(D) Amount to be carried forward to "founders' undivided profit account," per last year's report and accounts	4	9	2
	£8,115	18	9

The question of depreciation is not without its difficulty, but the directors believe that the amount set aside in addition to the expenditure on renewals, repairs, and maintenance is sufficient. The chairman, Mr. Eustace Balfour, and Mr. Latimer Clark, F.R.S., are the directors who retire by rotation under Clause 79 of the articles of association, and, being eligible, offer themselves for re-election. The directors propose to nominate Mr. Bennett Fitch, M.I.C.E, for election as an additional director. The auditors, Messrs. Deloitte, Dever, Griffiths, and Co., also retire, and, being eligible, offer themselves for re-election.

Revenue Account for Year ending Dec. 31, 1893.

The annual general meeting took place on Tuesday at the central station, Carnaby-street, W., under the presidency of Mr. Eustace J. A. Balfour (chairman).

The **Chairman**, in moving the adoption of the report and accounts, said he was anxious to give the shareholders as full information as possible on the various points raised, as well as some facts which bore upon the prospects of the Company for the coming year. It was a matter of regret that it was impossible to pay a dividend of more than 4½ per cent. on the ordinary shares. The following were, however, the chief causes which had led to this result. First, the year had been peculiarly free from fog. The ordinary citizen, when he woke in the morning and found it foggy, did not regard life as pleasant, but the electric light director paid no attention to his personal discomfort, as he realised that the day's earnings of his company would increase by 50 per cent. Another and second cause was the increase in their parish rating by about £570, and the amount they would now have to pay the parish was about equal to 8½ per cent. of the sum available for dividends. The chief cause had been the lowering of their charges forced upon them by competition with the London Electric Supply Corporation. In this connection the chairman referred to a speech made last May by Mr. J. Forbes, chairman of the London Electric Supply Corporation, and who had stated that all the companies had been guilty of folly in competition—unduly rushing down the rates—and that they were all between wind and water. Mr. Balfour was, however, so astonished, that he enquired if the report was correct. The correctness had not been denied, but the statement had not been withdrawn. In justification to themselves he was bound to say that Mr. Forbes was misinformed as to the action of his own company. It was only with great reluctance, and because their customers threatened to go to the London Electric Supply Corporation, that they consented to lower their prices. They disliked this policy, but they had no choice, trusting the time would come when the London Corporation would look at the matter as they did. The fourth cause was the increased economy shown by consumers, especially those on a large scale, some of whom, with the same number of lights wired, had actually diminished their consumption by 25 per cent. There were, however, many satisfactory features in the year's working, which showed that the business of the Company was on a thoroughly sound basis. The number of lamps wired had increased by 25 per cent. At the same time the cost of production had been sensibly diminished, and the directors would endeavour to maintain, and possibly increase, this economy of working. They had been obliged to exceed the estimated capital expenditure by about £11,000. This was due to the necessity of purchasing additional property, and increasing the output of that station by putting down additional boilers and machinery. The remainder was accounted for by the charges in connection with the Hopkinson case. The working of the system was satisfactory, and they had every reason to believe that the customers were satisfied with the light. The Chairman took the opportunity of thanking their staff for the energy and ability with which they had assisted them in carrying on the Company. Mr. Dobson was unfortunately taken ill last July, and, although happily much better, he was still abroad. His place had in the meantime been taken by Messrs. Andrews and Leach, assisted by the secretary.

Mr. Latimer Clark seconded the motion.

The **Chairman**, in reply to questions and criticism of shareholders, said that the cost of management had diminished this year, and he did not think they could find another electric light company in which those costs bore such a very small proportion to the whole cost. With regard to directors' fees, the question was settled three years ago, and the directors then gave an undertaking to which they had adhered. Concerning the litigation over the three-wire system, they were advised by experts on the matter, and it was much cheaper to combine with other companies than to fight it out alone. The second paragraph of the report, to which he referred them, was, he thought a complete justification for the policy pursued by the Company in the matter. They actually gained by defending the action brought against them. In the case of the legal proceedings in regard to the founders' shares, the directors had the strongest opinion of counsel that they would win their case on appeal, and the reasons why they lost that action on appeal were different from those in the first instance. As to further capital expenditure necessary, the reason for that was because they had to purchase property close to the station, and increase the capacity of output. One director had sold 30 shares during the year, and that was the only change. The investments had been changed to obtain a higher rate of interest. The directors had not determined how they were going to raise further capital, but the present proposal was to issue 4 per cent. debenture stock to the shareholders, to be issued only as wanted. The Chairman then put the motion for the adoption of the report and accounts and the declaration of the dividends therein mentioned. The resolution was carried, although not unanimously.

The retiring directors, Mr. Eustace J. A. Balfour and Mr. Latimer Clark, were re-elected, and Mr. B. Fitch was elected a director. The reappointment of the auditors, Messrs. Deloitte, Dever, Griffiths, and Co., concluded the proceedings.

EASTERN TELEGRAPH COMPANY, LIMITED.

The forty-third half-yearly meeting of this Company was held last week at Winchester House, under the presidency of Sir John Pender, M.P.

In moving the adoption of the report and statement of accounts, the **Chairman** said the gross revenue for the past half-year amounted to £369,967, as against £352,301 last year, being an increase of £17,576. There was an increase in the traffic with most of the places they were connected with, the principal being in the traffic with the Cape, India, and beyond. The total ordinary expenses for the half-year had amounted to £98,106, being a decrease of £691 as compared with the corresponding half-year. After paying for the debentures, the directors were able to pay the usual interim dividend for the half-year of 5 per cent., and carry forward the substantial sum of £86,500 to the reserve, the largest amount they had ever carried forward. The Board suggested that an extra remuneration should be given to themselves and to the staff. The directors were working for £1,000 less than they were entitled to by the articles of their association. The chairman expressed his pleasure at the completion of the cable connecting Lisbon with the islands of the Azores and the cable from Zanzibar to Seychelles and Mauritius, under an agreement with the Eastern and South African Telegraph Company. He reminded them of the value of their stock; the 4 per cent. debentures were worth now £116 in the market. They had only been 25 years in existence, and yet they were connected with the whole of the civilised world. He thought their prospects were most satisfactory.

The **Marquis of Tweeddale** seconded the motion, and the report was unanimously adopted.

COMPANIES' REPORTS.

LIVERPOOL OVERHEAD RAILWAY COMPANY.

Directors: Sir Wm. Bower Forwood, J.P.; Jas. Barrow, Esq., J.P.; J. Brancker, Esq., J.P.; H. Brocklebank, Esq., J.P.; R. Hobson, Esq., J.P.; E. Lawrence, Esq., J.P.; Geo. H. Robertson, Esq. Engineers-in-chief: Sir Douglas Fox, M.I.C.E.; J. H. Greathead, Esq., M.I.C.E. Engineer and manager: S. B. Cottrell, Esq., A.M.I.C.E. Secretary: Wm. H. Alexander, Esq.

Report of the directors to be presented to the eleventh ordinary half-yearly general meeting of the shareholders, to be held at the Law Association Rooms, 14, Cook-street, Liverpool, on Tuesday, February 13, 1894.

In presenting the half-yearly statement of the capital and revenue accounts to December 31, 1893, your directors have to report that the gross revenue receipts for the half-year amount to £18,518. 4s. 7d. The number of passengers carried being: First class, 260,221; second class, 1,293,840; workmen (special return tickets), 921,578—total, 2,475,639; making the total number of passengers carried since the opening of the railway, on March 6 last, 3,846,381. The electrical equipment continues to work very satisfactorily. During the past half-year 46,429 trains have been run, and 95·35 per cent. have been punctual. Your directors have taken over from the Electric Construction Company the electrical working of the railway from December 31, 1893, by which they hope to effect a considerable saving in the expenses. Progress with the northern extension was somewhat delayed by the coal

Digitized by Google

strike, but the work is now well in hand, and it is expected to be completed about the middle of March. Under the powers sanctioned by the shareholders on August 8 last, £25,000 of the remaining preference capital has been issued and fully subscribed.

Revenue Account.

The gross receipts from traffic amount to	£18,002	16	11
Miscellaneous receipts	515	7	8
	18,518	4	7
Less working expenses	13,732	11	5
	4,785	13	2
From which deduct interest on debentures and on calls paid in advance	2,627	1	10
	2,158	11	4
Add balance brought forward from last half-year ...	3,293	9	0
Leaving available for dividend the sum of	£5,452	0	4

Out of this balance your directors recommend the declaration of dividends at the following rates (less income tax), payable on and after February 16—viz , 5 per cent. per annum on preference shares, £978. 13s. 3d. ; 1 per cent. per annum on ordinary shares, £1,875 ; total. £2,853. 13s. 3d., leaving a balance of £2,598. 7s. 1d. to be carried forward to next half-year. The directors retiring by rotation at this meeting are Mr. James Barrow and Mr. Richard Hobson, who, being eligible, offer themselves for re-election. The auditor retiring by rotation is Mr. George Nicholson, who is also eligible for re-election.

The mileage of passenger trains is 243,539, and the amount paid on mileage to the Electric Construction Corporation under the contract for running was £4,058. 19s. 8d.

The Birmingham Cars.—A correspondent has written to a Birmingham paper as follows in connection with the electric cars on the Bristol-road: "With reference to the correspondence appearing in your journal as to the Bristol-road, what is the reason that the Central Company do not grapple with the accumulator difficulty more boldly? Anybody who has seen anything of the traffic upon the road knows perfectly well that what is wanted is a frequent service for the first part of the road, and a less frequent one for the remaining portion, and that the traffic occasionally on the whole of the line is very great. If the tramway company had enough accumulators to work a considerable number of cars in the way suggested they would make a profit, and not, as at present, a loss. To talk about working a three-mile line with three cars seems to anyone, except a director or a resident, an absurdity. It would be interesting to knew the opinion of someone who does understand something about tramway working on such a point."

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—The receipts for the week ended January 23 were £3,445.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending January 28 amounted to £632.

Cyfarthfa.—It appears that at the Cyfarthfa Steelworks it is contemplated to have the works illuminated with the electric light.

Cuba Submarine Telegraph Company.—For the half-year just ended the Board recommends a distribution at the rate of 8 per cent. per annum.

Telegraph Wire.—The United Kingdom last year exported telegraph wire and apparatus of the declared value of £1,065,767. The value of such exports in 1892 was £909,917.

Victoria Electric Railway Company.—Letters of allotment for the issue of £100,000 5 per cent. debentures of the Victoria Electric Railway and Lighting Company, Limited, have been posted.

Elmore's French Copper-Depositing Company.—Mr. Justice Wright, on the application of Mr. Buckley, Q.C., on Wednesday, sanctioned a scheme of arrangement which had been arrived at.

Porthcawl.—The Local Board have decided to defer the confirmation of the contract for lighting the streets with gas, in view of a public meeting of ratepayers which was to be held this week.

Kerbey Bowen, Limited.—This Company has been registered with a capital of £20,000 in £10 shares, to adopt an agreement, and to carry on business as ship and boat builders, electricians, engineers, etc.

Birmingham.—Next Tuesday a recommendation is to be submitted to the City Council to adopt a scheme of electrically lighting the Market Hall, at a cost of £1,000 for the necessary lamps, fittings, etc.

Dorking.—The question of providing electrical communication between the police station, the house of the captain of the fire brigade, and the water company's works, is under the consideration of the Local Board.

Froggatt's Electric Lighting Company, Limited.—This Company has been registered with a capital of £3,000 in £1 shares, to enter into an agreement, and to carry on business as electrical engineers, suppliers of electricity, etc.

Marine Steam Turbine Company, Limited.—This Company has been registered with a capital of £25,000 in £50 shares, to enter into an agreement with the Hon. C. A. Parsons, and to carry on business as engineers, shipbuilders, etc.

Kingswood.—Referring last week to the recent visit to Walsall, the chairman of the Local Board said he would like to hear the opinion of the Board in relation to the proposed electric tramway. A unanimous expression of approval was given to the scheme.

Denison Auto-Telegraph Machine Syndicate, Limited.—This Company has been registered with a capital of £1,000 in £50 shares, to purchase the letters patent of the Denison auto-telegraph machine, and to carry on the business of telegraphists and electrical engineers.

City and South London Railway.—The receipts of the Company for the week ending January 28 were £951, against £976 for the same period last year, or a decrease of £25. The total receipts for the first half-year of 1894 show a decrease of £115 compared with those for the corresponding period of 1893.

Messrs. C. A. Parsons and Co.—We are requested to state that by mutual arrangement Mr. A. A. Campbell Swinton has ceased to represent Messrs. C. A. Parsons and Co., and in his place Mr. C. P. Martin has been appointed their London agent. Their London office will continue to be at 66, Victoria-street, Westminster.

St. Saviour's, S.E.—A letter was read at a meeting of the Board last week from the City of London Electric Lighting Company, asking the Board's sanction to the use of their coat-of-arms at their new station on Bankside. It was stated that St. Saviour's had no coat-of-arms, and it was decided to inform the company accordingly.

Newcastle.—Last week, at a meeting of the Town Council, Mr. A. P. Andersen asked the chairman of the Lighting Committee if it was the intention of the committee to keep the present electric lamps in position near the Monument. Mr. Hepburn, in the absence of the chairman of the committee, said the lights mentioned might be regarded as temporary.

Aberdeen.—At a meeting last week of the Gas Committee of Aberdeen Town Council it was stated that Mrs. Stewart, wife of Lord Provost Stewart, would turn on the electric light on February 19 or 20. The meeting had also under consideration the supplying of electric light for the six lamps to be erected in Union-terrace. It was agreed that the lamps should be lighted.

King's Norton.—As mentioned in our last issue, Mr. R. Godfrey, A.M.I.C.E., the engineer and surveyor to the Rural Sanitary Authority, has submitted plans for an extension of the infectious diseases hospital, together with a report on the advisability of introducing the electric light into the whole of the institution. The question of the electric light was deferred for a month.

Sutton.—The clerk to the Local Board last week reported that the draft advertisements and draft specifications for the proposed lighting of the town by electricity had been finally settled by the General Purposes Committee, and that they were now ready for use. He had seen the officials of the Board of Trade as to the draft deed of transfer, and had revised the draft. The draft was referred again to the committee for further consideration.

Digitized by Google

Scarborough.—Tenders are invited by the 5th inst. for lighting by electricity the Council-chamber, court house, offices, etc., in the Town Hall, Castle-road, for the Corporation. A specification of the number of lights required may be seen and other information may be obtained at the town clerk's office, Town Hall. Tenders, marked outside "Tender for Electric Lighting," to be sent to Mr. John E. T. Graham, town clerk, Town Hall, Scarborough, by the date mentioned.

India Rubber, Gutta Percha, and Telegraph Works.—Subject to audit, the accounts to December 31 last show the following result: Net profit for 1893, £94,605; brought forward from 1892, £46,845; total, £141,450; less interim dividend, £25,000—£116,450. The directors have resolved to add £50,000 to the reserve fund, and to recommend a further dividend of 5 per cent. (making 10 per cent. for 1893) and a bonus of 2½ per cent., carrying forward £28,950.

Mine-Lighting.—Messrs. William Dixon, Limited, of Blantyre, have placed the contract for the lighting of the workshops, engine-rooms, pit-head, and pit-bottom, at their No. 4 pit, in the hands of the Faraday Electrical Engineering Company, Limited, Glasgow. The lighting is to be done by a single-field Faraday nine-unit dynamo driven by a Robey engine. There will be about 100 lights fitted up, including a number of 50 c.p., and there will be about 50 lamps taken down below to light up the roads, etc.

Aberdeen.—At a meeting of the Education Committee of Robert Gordon's College, the question of the lighting of the college was under consideration. For a considerable time the building has been lighted by electricity, but about nine months ago the dynamo in use was found to be worn out, and a new one was hired. Instead of continuing the hiring of this engine, however, the committee have now resolved to take the current from the mains laid by the Town Council; and at the same time it was agreed that Gray's School of Art should also be lighted in the same way.

Obituary.—An inquest has been held in Birmingham on the body of Henry William Gill, partner in the firm of Ash, Mill, and Co., electricians, Betchworth Works, Birmingham. It was stated that the deceased, who had patented a new electrical process which was being acquired by a London syndicate, remained at the office on Tuesday evening of last week printing letters. He afterwards drank a glass of whisky and water, from the effects of which he died, the water having been taken from a jug which had contained cyanide of potassium. Death was attributed to accident, and a verdict accordingly was returned.

Clacton.—The Local Board have received a communication from Mr. E. J. Gilders, who asked if the Board would entertain a scheme for lighting the town by electricity, or, if they were not prepared to do so, if they would support an application by a syndicate for the requisite powers to make such installation. The Board decided that they were not at present prepared to undertake the cost of an installation, but that they would be willing to support a syndicate on the understanding that the expense of lighting should not be greater than the amount already paid by the Local Board for lighting the streets with gas.

Islington.—At a meeting of the Vestry last week, Mr. Higginbottom called attention to the minutes of the Special Electric Lighting Committee of January 10, upon which were omitted the fact that the committee had enquired as to whether workmen in the employment of the Vestry should be so employed on any of the electric lighting works, and also as to a resolution that was passed. The Clerk said that it was not referred to the committee to report, but only to consider. The resolution passed by the committee was to the effect that the work to be undertaken was of a highly technical character, and the special committee did not deem it advisable that such an experiment should be entered upon.

Keighley.—At the eighth annual meeting of the Keighley Tradesmen's Association the question of electric light was discussed. Complaint was made of the dog-in-the-manger policy pursued by the Corporation, who had not only neglected to place the tradesmen in possession of business facilities enjoyed by smaller towns, but had prevented private enterprise from providing the electric light. The chairman explained what enquiries the Gas Committee of the Corporation were at present pursuing into the subject of electric lighting, and said he believed they would be willing to supply that illuminant whenever there was a sufficient number of prospective customers to make the production reasonably cheap.

Fowler, Lancaster, and Co., Limited.—This Company has been registered with a capital of £50,000 in £10 shares. The objects are to purchase or otherwise acquire and take over as going concerns the businesses carried on Birmingham and elsewhere by Fowler, Lancaster, and Co., Limited, and the Birmingham Telegraph Factory, Limited, to manufacture and let out or hire electric light and power, plant, and fittings, telegraphic and telephonic instruments and appliances, and generally to carry on the business of electrical engineers. The first signatories, with one share each, are: Thomas G. McLauchlan, Charles H. T. Bikker, Edward W. Lancaster, George E. Stembridge, Charles O. R. Pemberton, George M. Fowler, Walter Hands.

Edinburgh.—At a meeting of the Edinburgh and Leith Corporations Gas Commissioners the Works Committee minutes which were submitted contained a report by a sub-committee on the question of "The best means of encouraging the use of gas for industrial and manufacturing purposes," recommending that the Commissioners should allow the remit to drop. Councillor Kinloch Anderson said that the electric light was to compete with them in the way of illumination, and they would lose a great deal in the consumption of gas—in fact, it was estimated that they would lose the majority of their largest customers. If they entered into a system of this kind just now in respect of the amount of consumption of gas, and gave the remaining good customers an increased discount, the revenue would be very much decreased. Therefore it was thought wise at this particular time, and until they saw the effect the electric light would have on the gas industry, to delay taking any action in regard to the motion. The remit was agreed to.

Lighting at Windsor.—The *Windsor Gazette* says: "After vainly struggling to keep the plant going in the interests of the consumers, Messrs. Roger Dawson, Limited, have been compelled to stop running the electric light in the town. Mr. Farrow, their Windsor manager, received instructions to stop running the machinery on Monday. This is entirely due to the bad state of the mains laid down for the electric light company by Messrs. J. E. H. Gordon and Co., which are now practically useless on account of being eaten through in several places by electrolytic action, due to water getting across the two mains, the tar having in many places sunk and left the mains bare. No more light will be supplied until new mains are laid, which will be done at once if the Corporation will only allow the company to proceed. We understand the company have now proved to the Corporation that they are in a position to carry out the work. It would be a good thing for the unemployed if permission were given at once, as the laying down of new mains, building supply station, etc., would find work for 50 men at least for four or five months."

Leicester.—On a motion to attach the seal of the Corporation to a contract by Messrs. Hick, Hargreaves, and Co. for a pair of engines in connection with the electric light installation, Mr. Marshall proposed, at a meeting of the Town Council this week, that no contract be sealed until the members of the Council had received a detailed report from the gas engineer on the tenders from Messrs. Hick, Hargreaves, and Co., and Messrs. Jessop and Son. He said the reason of the amendment was that there was very little difference in the amount of the two tenders, and whilst the tender of the local firm was the lower by £50, the contract was given by the committee to the Bolton firm. He submitted that, on the showing of the engineer, the rejected design was an excellent one, and that if possible the work should be kept in the town. The amendment having been seconded, Alderman Lennard, chairman of the Gas Committee, defended the action of the committee in accepting the higher tender, on the ground that although Messrs. Jessop's was a very good design, the other was, in the opinion of the engineers, a better one, and that the engines agreed upon would be better value than those of the local firm. He, however, was willing to accept the amendment on condition that the report be received from the engineer, and discussed without delay. They were under an undertaking to complete the installation by July next, and if there was a delay of a month in placing the order for the engines it would put them out with the whole undertaking. The motion was ultimately withdrawn, and the amendment agreed to, the report of the engineer to be discussed at a special meeting of the Council.

Easton, Anderson, and Goolden, Limited.—This Company has been registered with a capital of £200,000 in £10 shares (of which 10,000 are 6 per cent. cumulative preferred). The objects are to acquire and take over as a going concern by way of reconstruction the undertaking of Easton and Anderson, Limited (incorporated in 1888), and all or any of the assets and liabilities thereof, and to carry on the business of civil, mechanical, and general engineers, millwrights, shipbuilders, etc. The signatories are Thos. P. Wilson, Frank S. Courtney, J. E. Compton-Bracebridge, Edward W. Anderson, Walter T. Goolden, Llewelyn B. Atkinson, Jas. R. Easton. The new company is an amalgamation of Messrs. Easton and Anderson, the old-established engineering firm, of London and Erith, with Messrs. W. T. Goolden and Co., electrical engineers, Woodfield Works, Harrow-road, London. The former firm, who for so many years have had an extended connection in hydraulic and general engineering work, have more recently been paying attention to the development of electrical transmission. In their Erith works for some four years travelling cranes of 15 and 20 tons have been in work, driven electrically. A special department has been established in their works for the execution of various electrical work. The firm of Goolden and Co. have been prominently before the public in connection with the application of electrical transmission in mines. The nature of the electrical work of each firm being so similar, the combination of the two should lead to an increase of business on either side, as the new company will be in position to carry out in its entirety all the work in connection with a large electrical installation, either for transmission of power and for lighting.

Railway Rates.—The Secretary to the London Chamber of Commerce has issued a circular as follows: "As the railway companies (apparently in concert) are pressing for the payment of the balances of their accounts for 1893, I am instructed to renew the recommendation repeatedly made by this Chamber to its members, not to pay any rates higher, or to accede to any conditions of transport more onerous, than those which were in force in 1892. This action is confirmed by the recommendation of the Select Committee of the House of Commons on Railway Rates and Charges, which states: 'Your committee are of opinion that the margin between the old actual rates and the present parliamentary maxima was not given by Parliament in order that immediate advantage should be taken of it, or that the policy of recoupment should be carried out. Your committee, then, are of opinion that some further steps must be taken to protect traders from unreasonable raising of rates—even within the maximum charges defined by Parliament—and from the imposition of such unreasonable conditions of transport as

Digitized by Google

cannot now be made the subject of arbitration. They are of opinion that where, in the case of the raising of a rate, a trader complains that it is excessive or unreasonable, and the conciliation clause fails to result in an amicable settlement between a company and a trader, the petitioner should be at liberty to go before the Railway Commission, and that in such case the Commission should be empowered to decide whether the increase is reasonable or not. In order to meet the cases of the raisings of rates within the present year, which have been the main subject of complaint to your committee, they are of opinion that the power thus proposed to be given should be retrospective to the extent that traders who petition the Board of Trade within a reasonable time in respect of rates increased within the present year should be allowed to go before the Railway Commissioners in the manner recommended. The Chamber will be prepared to lodge, on your behalf, with the Board of Trade a statement of the amounts overcharged by the companies during 1893, and if you are desirous of making use of the Chamber for this purpose, I shall be glad if you will forward such statement at your earliest possible convenience. This need not be in detail, but it will suffice if it indicates the total amount of difference, say, for each separate month, or for as many separate months as it is possible for you to sustain your accounts. It is very desirable that no delay should occur in sending in these statements."

Lighting in the West-end.—The Highways Committee of the London County Council reported on Tuesday that they had considered a notice from the Metropolitan Electric Supply Company of intention to lay mains in Elgin avenue and road, Carlton road and hill, Edgware-road, Portsdown-road, Abercorn-place, Hamilton-terrace, Upper Hamilton-terrace, Abbey road, place, and gardens, Violet-hill, Nugent-terrace, Alma-square, Hill-road, Garden-road, Grove-end-road, Loudoun-road, Elm-tree-road, Circus-road, Hall-road, Melina-place, and Stranraer-place. To these proposed works the committee show no objection, but having regard to their large extent they were of opinion that should any of them not have been commenced within six months of the date of approval a fresh notice should be given in respect of those deferred. They recommended, therefore, that the sanction of the Council be given to the works referred to, on condition that the company give two days' notice to the Council's chief engineer before commencing the works in any thoroughfare referred to; that the mains be enclosed in iron pipes or efficient casing, and be laid under the footways wherever it is found practicable to do so; that as an additional precaution against accident through defective insulation of the mains, each of the street boxes shall be provided with an inner as well as an outer cover, the two insulated from each other as far as practicable, and that the outer cover, which shall consist of an iron frame filled in with material to suit the paving, shall be efficiently connected to earth; that the works be in all respects similar to those approved by the Council on previous notices of the company; and that if from any cause any of the works referred to in the notice be not commenced within six months from the date of the Council's notice of sanction, such sanction shall be held to have expired, and a further notice shall be given by the company and the Council's sanction obtained before such works shall be proceeded with. The committee had also considered a notice from the St. James's and Pall Mall Electric Light Company of intention to lay mains for a short distance on the west side of Regent-street. The proposed works are unobjectionable, and the committee recommended that the Council sanction the works referred to on condition that the company give two days' notice to the Council's engineer before commencing the works; that the covers of the street boxes be supported on 3in. York stone; and that before the street boxes are constructed the designs for, and the proposed positions of them, be submitted to and approved by the Council's chief engineer. The committee had likewise received a notice from the Kensington and Knightsbridge Electric Lighting Company of intention to lay mains in a part of De Vere-gardens. The committee recommended that the Council sanction the works referred to.

Electric Lighting in St. Pancras.—The Finance Committee of the London County Council on Tuesday presented a long report upon an application of the St. Pancras Vestry for £30,000 for 42 years, on the annuity system, for electric lighting purposes. The committee stated that the Council had already sanctioned loans for £10,000 for the purchase of a site, repayable in 50 years, and £60,000 for works, repayable in 42 years. The £10,000 was advanced by the Council, and the £60,000 borrowed elsewhere, as the Council had no power at that time to lend for a longer period than 30 years. This restriction was, however, removed by Section 7 (iv.) of the Money Act of 1892, and the term of 50 years fixed as a maximum limit. On July 25th last they reported on the Vestry's application for a further loan of £30,000, when they recommended (having regard to the amount already borrowed and to certain other circumstances referred to in their report) that the loan should be limited to £15,400. The Council concurred in their recommendation that the repayment of that sum should be spread over 42 years. The Vestry had not taken up this loan, and now renewed their application for the £30,000. The life of the different portions of the work having to be considered, the only satisfactory way of dealing with the present application appeared to be to consider it as part of an application for £90,000, on account of which £60,000 had been sanctioned. It must be borne in mind that an electric light undertaking differed from many other undertakings, in that a very large proportion of the total cost was in respect of works of a short-lived character. The Vestry contended that they should be allowed a longer period than one based upon the life of the work, in order that they might have equal advantages with an electric light company which did not have to pay off its capital, but, even if this be admitted, it must be remembered that a company could not borrow money at 3½ per cent. as the Vestry could, and that a company had to establish a reserve fund to meet depreciation and other contingencies. These considerations led to the conclusion that practically the only safe course for the Council to adopt was to sanction the loan for a term approximating to the life of the work. And there would be this advantage in the course suggested, that the Vestry would be justified in borrowing again for renewals. If the Council accepted this view the present application might be granted as follows: £2,500 for five years, £4,200 for eight years, and £23,000 for 15 years, and in this event the resolutions of July 25 last, agreeing to sanction and lend the Vestry the sum of £15,400, should not be further proceeded with. The committee recommended accordingly. Mr. J. Williams Benn, M.P., moved, as an amendment, "That the recommendation be referred back to the Finance Committee, with an expression of opinion that the total initial cost should be extended over a reasonable period, and without regard to the life of any particular portion of that which forms initial cost, and that the Finance Committee should be at liberty to take such professional advice in addition to that of the officers of the Council as the committee may think fit." Mr. McCall seconded, and, several other members having condemned the recommendation as being prohibitory to electric lighting being taken up by local authorities, the amendment moved was adopted.

The Tramway Question in Leeds.—In the course of an article dealing with the future of the Leeds tramways a local paper says: "In Birmingham the working cost of the cable tramway is 6·18d. per car mile, while that of the electric system in this city is between 5½d. and 6d. This was the rate which Mr. J. E. Winslow, the manager of the Roundhay Park line, gave a representative. But what is the cost of putting down the electric system? Mr. Winslow, who, as engineer for the Thomson-Houston Company, has just completed the electric tramways in Milan, says it would be between £4,000 and £5,000 per mile. Say, £5,000. This would entail an expenditure for the 50 miles of £250,000, as compared with £550,000 for the cable—a difference in favour of the electric of more than one half. The latter would comprise a complete installation, including generating station, well-lighted double-decked cars, and all wires, with the feeder placed underground. Mr. Winslow suggests two sizes of cars—one all covered in, and the other open at the sides on the top. The Thomson-Houston system on Roundhay-road has been very successful so far as the service is concerned. But objection is taken to the overhead wires. An underground system is undoubtedly to be preferred, but, as is obvious, that would entail a much greater expenditure, and it is not certain that it would be as reliable. In a busy city such as Leeds difficulty might be experienced in preventing the slot in the track, through which the car obtains motive power, from getting clogged with dirt, and in maintaining the service when the ground was covered with snow. With the overhead electric system no such risk has been experienced. As for the unsightliness of the wires, it is affirmed by those who live along Roundhay-road that the eye soon becomes accustomed to them, and that the great convenience of the tramway service makes them more than tolerable. There is another important consideration. The establishment of a cable system, even if it were desirable on other grounds, would probably occupy three or four years. Of course, much would depend upon the number of men set to work. On the other hand, it is certain that an electric installation such as we have on Roundhay-road, could be supplied much more expeditiously. Mr. Winslow thinks there would be no difficulty in providing a thoroughly equipped service in 18 months after the lines were handed over to the Corporation. He would at once carry the installation from Sheepscar forward to Briggate. Meanwhile he would proceed with the erection of an electric power station for the whole city, somewhere close to the river where water for the engines could be obtained, and where fuel could be had without cartage. The wires would be laid along the other tracks as fast as they were put into proper order, and in six months the erection of the power station would be so far advanced as to enable cars to be placed upon sections which were then ready. The electric system would give an additional advantage. The thoroughfares traversed could, like the cars, be lighted by electricity, the standards supporting the overhead wires being used for the purpose. Mr. Winslow suggests that the cars should be run 18 hours a day, with a double shift. On the Roundhay-road, in the winter, they start at 20 minutes to 7 a.m., and the last journey is commenced at 11.30 p.m. In summer they commence an hour earlier in the morning. The men are employed 10½ hours to 11 hours per day, the drivers averaging 31s. per week, and the conductors from 24s. to 25s. Last year, says Mr. Winslow, although the line is unconnected with the other tramways, and commences at a considerable distance from the centre of the city, it paid the working expenses. Another interesting fact in connection with the enterprise is that in the first year of running the passengers increased from 700,000 to 800,000." The proposed conditions for letting the tramways have been drawn up, and one portion of these refers specifically to electric traction as follows: "On the determination of the lease the Corporation refuse to be under obligation to purchase any buildings or effects used in connection with or on the tramways; these must therefore be removed. In the case of electric traction, wires under the road must be left for use or disposal of the Corporation without payment to the lessees, unless they can be removed without disturbing the road. The lessees are required to pay by way of security the sum of £10,000, which is to be invested in the joint names of the Corporation and the lessees, the interest to be paid to the lessees; and should there be any breach of regulations the lessees will be liable to a fine of £10 per day during the default,

Digitized by Google

and expenses in addition. In the event of the Corporation accepting any offer to lease the tramways, a formal lease containing the above-mentioned and any other conditions deemed necessary will be drawn up and submitted to the Board of Trade for final settlement."

Newport and the Electric Light.—The Electric Lighting Sub-Committee of the Parliamentary Committee of the Newport Corporation on Friday last inspected the high-tension installation which Messrs. Crompton have recently erected at Chelmsford, and afterwards visited another installation provided by the same firm in the Metropolis. Following this, a meeting of the whole committee was held on Monday for the purpose of again considering the question at issue. There was a large attendance, and the whole matter was discussed. As the result of the meeting, we are informed, the committee will adhere to their original recommendation to the Borough Council, which was that the tender of Messrs. Fowler and Co. be accepted. The following comment is taken from a local paper: "It must be said for the Parliamentary Committee of the Newport Borough Council that in connection with the electric lighting of the town they have proved themselves remarkably consistent in their inconsistency, and firm—stubborn is the better word perhaps—when a graceful withdrawal from a false position still remained an easy way out of a serious difficulty. Altogether ignorant of the science of electricity, excusable from their utter lack of experience, they allowed themselves to be far too easily induced to recommend the acceptance of one tender for the construction of the entire works. As they had previously decided that the contract should be given out in about a dozen sections, thereby dividing it between a similar number of firms or companies, this, by itself, was a complete reversal of their original recommendations. The tender they favoured, too, was two or three thousand pounds in excess of the one considered by them as second in point of merit, but regarded as the better one by experts and professional writers of many years' standing. The support given by Mr. Hammond, the borough electrical engineer, to the tender of Messrs. Fowler, was doubtless the one potent factor in securing its recommendation. When the business connections of this gentleman with this particular firm, however, came to be so ruthlessly disclosed, the Parliamentary Committee must have felt equally as strongly as the public has done, that his advice was by no means as disinterested and impartial as his employers had a right to demand. When the Council, as a body, came to consider and discuss the report, they doubtless felt that it was more than possible the committee had been unwittingly led into committing a serious error. If they were not of this opinion, they would scarcely have adopted the step of referring the tenders back to the committee for reconsideration. The committee themselves, for a short time, must have shared in this opinion, inasmuch as at a special meeting they decided, after a most lucid explanation by Mr. Crompton, the tender of whose firm was the second one alluded to, to postpone any further recommendation until they had reconsidered the matter again. Since then Messrs. Crompton, as showing their anxiety for undertakings of a similar nature carried out by them to be personally inspected by the committee, invited this body to Chelmsford to go over one of the firm's latest works, and this has been done. No change, however, is to be effected in the original recommendations. One of three things has happened. The committee perhaps are still completely under the influence of Mr. Hammond, and find themselves with insufficient backbone to make a real effort to rid themselves of the incubus. It may be that they are conscious of the error they have committed, but are determined to stand by it rather than that their supposed prescience and safe judgment shall run the risk of being weakened in the opinion of the ratepayers; and it is just possible that they are honestly convinced that, after all, their original recommendation was a wise one, thus justifying them in abiding by it. At all events they did this at a further special meeting held on Monday. Yet the entire matter is enveloped in so much doubt that the Council will be far more than justified when next they meet in discussing it with perfect freedom, and, if necessary, without paying but little regard to the actual recommendations of the committee. This may appear to be treating the latter body with a certain amount of discourtesy. The issues at stake, however, are so important, and the present amount involved so large, to say nothing of the outlay to follow, that the Council must fearlessly do its duty. What that duty is appears remarkably plain."

Conversazione of the Swindon Junior Engineering Society.—The members of the Junior Engineering Society in connection with the Swindon G.W.R. Mechanics' Institution spent an enjoyable time with their friends at a conversazione in the large hall of the institute on Tuesday of last week. The society, which has been in existence some 15 months, and already boasts of a membership of about 80, receives encouraging support from the leading officials in the works, Mr. W. Dean being president, and the vice-presidents' list containing, in addition to the name of Mr. N. Story-Maskelyne, those of Messrs. S. Carlton, G. J. Churchward, D. E. Marsh, E. C. Riley, W. H. Williams, and W. H. Stanier. There was a very large company at the gathering, and the programme was sufficiently varied to suit the tastes of all. Besides an interesting address by Mr. N. Story-Maskelyne some excellent selections of music were given, while during the latter part of the evening dancing was a great attraction. But without endeavouring to minimise in any way the merit of these forms of enjoyment, it must be said that the exhibition of working models, microscopes, electric lighting appliances of different kinds, etc., was fully as interesting from the point of view of many of the company as well as in the opinion of the students. In the centre of the room was a novel feature in the form of an electric fountain, lighted with incandescent lamps, the design and work of Mr. H. G. Cotsworth. An interesting exhibit by Mr. G. B. Clifton comprised a Willans-Robinson engine. Thanks are especially due to Mr. W. L. Holt, who was untiring in his efforts to get an interesting collection of specimens—efforts which, it is hardly necessary to say, were fully successful. On the stage was a collection of electrical appliance, microscopes, etc. Conspicuous among the latter was a first-class Powell and Lealand microscope, kindly sent by Mr. Story-Maskelyne, and brilliantly illuminated by an electric lamp. During the first half of the evening the stage was lighted by 10 16-c.p. electric lamps worked from a dynamo in the basement, the arrangements for the supply of the current being carried out under the personal supervision of Mr. E. J. Tincknell. Other exhibits comprised Thompson's calorimeter, a specimen of electric welding, a compound cable of steel and iron lent by Mr. Thomas, etc. Some of the most interesting exhibits were those sent by the Lithanode and General Electric Company, London, whose general manager, Mr. J. T. Niblett, was present. Miners' safety lamps were shown in two forms, and were guaranteed to be perfectly safe, even in the most dangerous surroundings. The smaller size, which will run from eight to ten hours, costs only ¼d. for electricity per shift; while in the case of the larger lamp, which lasts from 12 to 14 hours, the cost is about ½d. A lamp was also shown for railway carriage reading, as well as a three-cell hand lamp with fixed lantern. Another interesting exhibit was an 8 c.p. incandescent electric lamp supplied from a six-cell, 30-ampere hour accumulator, and made for the Glasgow Corporation for illuminating their new tramcars; and a five-cell, 18-ampere hour lamp for omnibuses and trams, the connection being established by the driver dropping the battery into the box. Samples of the different plates used in installation, with plates, cells, and all the mechanism of miners' lamps were explained separately. In the course of his address, Mr. Story-Maskelyne said: "How wide is the range of subjects that fall within your ken is evidenced by the programme of your current session. I find discourses on such widely-different subjects as fuel, to which an entire volume of the last technological encyclopædia is devoted to; lubricants, a subject involving important questions as to the mechanics of friction; measurement of temperature, the difficulties of which begin when we pass from the regions covered by our ordinary thermometers to pyrometers, and other modes of estimating very high or very low temperatures; electric measurements and their units; water power, and the various ways of using the potential energy of stored water; the chemistry and metallurgy of copper, that, after iron, most important metal—important for its useful and beautiful alloys and for its conducting power, and also as illustrating the influence of minute amounts of extraneous ingredients in modifying the properties of a metal. Why, gentlemen, here are subjects that all bear on engineering in the most direct manner; and what a vast field does practical engineering now cover: the whole range of mechanics is its own: the several branches of physics, including heat and thermo-dynamics and electricity, are no less within its sphere, and chemistry and metallurgy also bring their tribute to the practical engineer. Of these subjects many need mathematics, are, in fact, unintelligible except to the man who has mastered something of that great language of nature. I need hardly urge on you to seek every opportunity of extending your grasp of mathematical methods. You will hardly aim at announcement of discoveries in science. Your time is, I opine, too fully occupied for the long and laborious investigations which lead to new scientific truths. But a large field of invention is open to you, for this needs thought and originality founded on facts and principles already established. The annals of your society may well be gilded by the record of improvements in methods and apparatus and in machinery suggested to you in your daily contact with engineering problems. The highest order of discovery belongs to men who can give long hours to research. The man of science—the philosopher, as Faraday persistently called him—simply ignores usefulness. His aim is a lofty one—the advance of man in the knowledge of the sublime laws that preserve the order of the universe. Practical results are the by-products of his work, the chips from his workshop. Pick them up where you can; it is yours to utilise them for the daily use of man. But reverence their source! Some arts are older than the sciences that illustrate them; such as agriculture, metallurgy, and many of the domestic arts. But he would be foolish indeed who scoffed at the science that explained the art, and pointed the way to its improvement, even though some of its problems remained still unsolved. Other arts again are born of science. They are its children. Steam, chemical industries, including gas, are so. Electric and electromagnetic science is emphatically the offspring of research, and of the highest mathematical analysis. If the nomenclature of electric science honourably recalls the names of some of the greatest experimentalists of a past fruitful century in the Watt, the Volt, Ohm, Ampère, Faraday, and Coulomb, our own latter half of the Victorian era has its Clerk Maxwell, Helmholtz, Kelvin, Hertz, Fitzgerald, and, let me add, its Larmor, to point to as among the great mathematical thinkers who have made electricity the most important of sciences. And what are the by-products of all this magnificent work? Well, you have the telegraph, the telephone, the electric light, the transfer of energy from place to place by the simple agency of a copper wire. And let me here for a moment detain you to point out another step we may expect soon to see taken. You may first ask me perhaps, What is electricity? Men not long ago asked, What is heat? There were those who thought

Digitized by Google

heat was a subtle substance that was passed into or out of the supposed pores of matter, and discussions have been held as to whether there were two or only one electricity. We now not only know that heat is but a form of energy—in fact, a mode of subtle motion—but, thanks to Joule, we are able to assign its equivalent in the work it can cause to be done. We have our heat unit. We have, too, our electric units, yet we are still unable to give a complete answer to this question. What is electricity? To return to my point, I can only here allude to that immortal dream of Clerk Maxwell that, as the ratio of the expressions for the electrostatic to those for the electromagnetic units had the mathematical form of a velocity, the ratio of a distance to a time, and as the velocity so calculated approximated to the velocity of light (183,000 miles in a second), and must be propagated through some sort of dielectric medium corresponding to the ether, therefore light might perhaps be an electromagnetic emanation. A German philosopher, Hertz, who died but three weeks ago on the banks of the Rhine, at Bonn, proved the vision of Clerk Maxwell to be a physical truth. He showed that heat and light are, in fact, identical in character with electromagnetic disturbance in the ether ocean that fills all space and penetrates all matter, a disturbance of the character of waves: such waves he proved to emanate from a wire through which a rapidly-oscillating electric current was being transmitted. They differed from heat and light waves only in their greater length of wave. As the pedal pipes of an organ form one extremity of the long series of octaves at the other end of which are the treble notes, so these waves belong to octaves where the vibrations are profoundly 'bass' (many yards in wave-length), while the luminous rays that we call light comprise barely a single octave somewhere in the higher region of the long gamut of ethereal pulsations, 50,000 of them recurring in a single inch. Why do I dwell on this fascinating theme? Well, for a practical purpose. You are aware that, of this long gamut of pulsation, we already know that quite at the treble end the invisible rays beyond our visual ken are the most effective in producing chemical (photographic) changes, such as bleaching dyes and stimulating plant life. The visual rays perform this function, too, besides having heating properties, while beyond the visible rays in the direction of the bass end of the gamut the heat rays are the most effective. These attributes belong to each single ray, not to different commingled rays. But in order to produce an electric light of any useful intensity, we have to expend an amount of work far beyond what should be necessary to impart to the ether that luminous thrill. This is chiefly expended in producing waves of longer wave-lengths that have no luminous effect for our eyes. The problem, then, is to find the means of producing only the rays we want without this prodigious waste. You will ask, Can it be possible? The answer is, Yes, it must be possible. The firefly on a small scale does it, so does the

'Glow-worm golden in her dell of dew
Scattering unbeholden her aerial hue
Amid the flowers and leaves that screen her from the view.'

This, then, is a practical problem within the sphere of the practical electrical engineer. I put it before you as one of the great economical steps that may be taken in the immediate future, and to which every ingenious and thoughtful mind may be usefully directed, and it serves as an illustration of the main idea that runs through the discourse with which I fear I have wearied some portion at least of my audience who have come here to-night for a different variety of entertainment."

PROVISIONAL PATENTS, 1894.

JANUARY 22.

1320. **Improved electrical insulated fitting.** Charles Cunningham Connor, Notting-hill, Belfast.

1356. **Improvements in electrolysis.** Emile Andreoli, 18, Somerleyton-road, Brixton, London.

1375. **Improvements in rapid telegraphic transmission.** Charles Langdon-Davies, 24, Southampton-buildings, Chancery-lane, London.

JANUARY 23.

1417. **Automatic device for removing resistance in starting electric motors and replacing same.** George Herbert Whittingham, 52, Chancery-lane, London. (Complete specification.)

1433. **Apparatus for advertising by means of electric lamps.** William Falconer King, 154, St. Vincent-street, Glasgow.

440. **Improved electric battery.** John Peel, 8, Quality-court, Chancery-lane, London.

1473. **Improvements in dynamo-electric machines.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (George Frederick Dieckmann, United States.) (Complete specification.)

1478. **Improvements in connection with phonographs, grammaphones, graphophones, and similar sound recording and reproducing instruments.** Jonathan Lewis Young, 4, Moorfields, Fore-street, London.

1491. **Improvements in arc lamps.** John Brunswick Barton, Norfolk House, Norfolk-street, Strand, London. (William Jandus (United States.)

1495. **Improvements in commutator brushes.** William Lloyd Wise, 46, Lincoln's-inn-fields, London. (Otto Hering, Germany.)

1479. **Self-acting hydraulic apparatus for winding up mechanisms actuated by weights or springs, such as Hughes telegraphic type-writers, Morse telegraphs, etc.** Robert Howe Gould, 55, Holborn-viaduct, London. (Complete specification.)

JANUARY 24.

1532. **An improved system of metering electric currents.** Ernest George-Pink, 10, Seville-place, Dublin.

1542. **Improvements in or relating to facsimile telegraphy.** Harry William Charles Cox and Richard Joseph Crowley, Harbour-row, Queenstown, Ireland.

1582. **Apparatus and process for converting heat into motive power or electricity (or both) and for cooling and refrigerating.** Frederick Stone, 62, Uttoxeter New-road, Derby.

JANUARY 25.

1605. **Improvements connected with incandescent lamps or burners.** Harry Tee, 15, Water-street, Liverpool.

1657. **A method of and apparatus for communicating electricity to vehicles.** Henry Percy Holt, 28, Southampton-buildings, Chancery-lane, London.

JANUARY 26.

1686. **Improvements in propelling locomotives by electricity and in apparatus therefor.** Rankin Kennedy, 1, Clifton-villas, Camden-square, London.

1698 **Improvements in telephone transmitters.** Richard Steenberg, 3, St. Nicholas-buildings, Newcastle-on-Tyne.

1701. **Improvements in and connected with electric conduits.** Carrington Riddell Gordon Smythe and Archibald Hendry Dunnachie, 154, St. Vincent-street, Glasgow.

1744. **Improvements in electro-deposition.** William Stepney Rawson, Cadby Hall Works, Hammersmith-road, London.

JANUARY 27.

1776. **Improvements in electric arc lamps.** William Aloysius Walton, London-road, Gloucester.

1788. **Improvements in electric glow lamps.** John Pitt Bayly, 18, Fulham-place, Paddington, London. (Wilhelm Wiklund, Sweden.)

1794. **Improvements in electrical traction or electrical railways and tramways.** William Adkins, 6, Livery-street, Birmingham.

1798. **Improvements in electric signalling apparatus, and in apparatus connected therewith.** John William Fletcher, The Homestead, Cale-green, Stockport.

1810. **Improvements in electrical measuring instruments.** Harold Edward Sherwin Holt, Broom Hall Works, Teddington.

1849. **An improved arc lamp.** Frank Taylor, 45, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1889.

19153. **Phonographs.** Hardingham. (Edison.) (Third edition.)

1890.

7932. **Mandrels for electrolytically-deposited tubes.** Elmore. (Second edition.)

12628. **Welding metals by electricity.** Fowler. (Second edition.)

1893.

238. **Galvanometer.** Sullivan.

660. **Battery elements.** Pickard and Thame.

3101. **Insulating armatures of dynamo-electric machines.** Jefferson.

3831. **Telephone exchange systems.** Kingsbury. (Western Electric Company.)

4390. **Electric arc lamps.** Cannevel.

4772. **Metal arms for supporting telegraph insulators, etc.** Marsh.

21630. **Telegraphy.** Delaney.

22253. **Railway electric signals.** Bradrick and Karr.

NOTES.

Scarborough.—The Sanitary and Lighting Committee of the Scarborough Corporation have resolved to introduce the electric light in the Town Hall.

Legal.—Dr. Tibbits has again been unsuccessful in his actions brought against newspapers for alleged libel. This time it is the *Morning* which has won the day.

Harrow.—A Local Government Board enquiry will shortly be held with respect to the application of the Local Board to introduce the electric light in the district.

Blackpool.—As mentioned in another column, the Blackpool Town Council voted the sum of £24,000 on Tuesday for extensions of the electric light works.

Wigan.—The Town Council are granting an extension of time for householders to send in replies regarding the supply of current, and they have also modified their terms.

Wiring.—The Shoreditch Vestry have commenced an artisans' class in wiring and fitting work at a nominal fee of 2s. 6d. per term at the Municipal Technical Schools, 35, Hoxton-street.

Mill-Lighting.—The members of the Ramsbottom Local Board recently inspected the electric light installation fitted up in the mills of Mr. Alexander Barlow, Bridge Mills, Edenfield.

The Heilmann Locomotive.—It is stated that the experiments in electric traction made at Havre, under the auspices of the Western Railway of France, have yielded satisfactory results.

Leeds.—The Corporation have now taken over the undertaking of the tramways company. A decision has not yet been arrived at as to what system of traction will be adopted on the lines.

Sunderland.—On Wednesday the Town Council decided to accept tenders for the erection of an electric lighting station, subject to the sanction of the Board of Trade and the Local Government Board.

A Peculiar Accident.—An explosion of gas occurred in the Philharmonic Restaurant at Cardiff on Monday, in connection with a gas-engine used for driving a dynamo lighting the premises. Three men were injured.

The Royal Agricultural Society Show.—The Duke of Devonshire presided on Wednesday at a council meeting of the Royal Agricultural Society of England, when an invitation to hold next year's show at Darlington was accepted.

The Guilds Central Technical College.—The Executive Committee of the City and Guilds of London Institute have changed the name of the Guilds Central Institution in Exhibition-road to that of the Guilds Central Technical College.

Traction at Cardiff.—Mr. S. Hern, a director of the Cardiff Tramway Company, stated a few days ago that if the electric light plant became available for propelling tramcars, the company would take every opportunity of introducing that method.

Battersea Polytechnic Institute.—No less than 159 students have enrolled themselves in the mechanical engineering department, and there are 111 students in the classes dealing with electrical subjects, that in electric wiring being the most popular and largely attended.

Stafford.—The Electric Lighting Committee of the Town Council recommended on Wednesday that tenders should be invited for the construction of a dynamo and engine house, with a two-storey building to be used as a store, testing-room, offices, etc. The report was adopted.

Lighting in Kensington.—During the past year the number of houses and shops connected with the system of the Kensington and Knightsbridge Electric Lighting Company has increased from 550 to 734, while the number of lamps calculated on the basis of 8 c.p. has increased from 47,441 to 64,529.

The "Medical Battery" Company.—The week allowed by Mr. Hannay for the prosecution in the Harness case to consider whether they would proceed under the Vexatious Indictments Act having elapsed, and they having taken no steps in the matter, the case may now be considered at an end.

Holyhead.—The price of gas for illuminating purposes has recently been advanced by the local company to 5s. per thousand. Complaints against this are now being made, especially in view of the decision to supply gas for cooking purposes at 3s. 10d. The introduction of the electric light should prove a great success.

Proposed Colombo Electric Tramways.—A correspondent writes to a Ceylon paper pointing out various objections to the proposal to lay electric tramways, and suggesting that omnibuses would be much more suitable. The Ceylon paper says that it would be well to wait until it is seen how the Madras scheme works.

Another Belt Case.—Francis McOnville, *alias* Prof Hamilton, has been committed for trial at Liverpool on a charge of obtaining £50 by false pretences from John Gardner, by representing that he was a medical man, and that an alleged "electrical belt" which he sold to Gardner would cure a disease from which he was suffering.

Electric Lighting of Pianos.—A demonstration has just been given of a method of lighting pianos by electricity. The current is obtained from an accumulator which will give light for between 18 and 20 hours. Each lamp—there is one on each side of the piano—gives a 3-c.p. light. The battery is contained in a receptacle behind the music desk.

Lectures.—A lecture on "The Scientific Work of Galileo" has this week been delivered by Prof. Fleming before the members of the Leeds Philosophical and Literary Society. Under the auspices of the Yorkshire Ladies' Council of Education, a lecture has been delivered in Leeds by Mr. Robert Hammond, M.I.E.E., on "The Electric Light in our Homes."

Society of Arts.—The fourth Cantor lecture on "The Detection and Measurement of Inflammable Gas and Vapour in the Air," by Prof. Frank Clowes, D.Sc., will be delivered on Monday. On Wednesday next, at 8 p.m., Prof. Henry Robinson will read a paper on "The St. Pancras Electric Light Installation." Mr. W. H. Preece, C.B., F.R.S., will preside at this meeting.

British North Borneo.—A correspondent of a daily paper mentions that in 1889 the Eastern Telegraph Company, at the request of some of the subsidiary companies in North Borneo, proposed to connect Borneo with Singapore and Hong Kong. The proposal was favourably reported on by Admiral Salmon on behalf of the Imperial Government, but the scheme fell through owing to want of support by the Chartered Company.

Institution of Mechanical Engineers.—A reception committee, with the Lord Mayor of Manchester as chairman, and the Mayor of Salford as vice-chairman, has been formed in Manchester in view of the visit of the Institution of Mechanical Engineers to Manchester this year. It was mentioned that the visitors would have the Ship Canal, the electric light station, the hydraulic power plant, the sewerage, and the Thirlmere waterworks to see on this occasion.

Digitized by Google

A Funeral Car.—An electric funeral car has recently been constructed by one of the San Francisco tramway companies for the San Mateo Cemetery, at a cost of £500. The car has been named "Cypress Lawn." It is 30ft. in length, and is divided into two compartments—the forward 20ft. in length, and the rear 10ft. As San Francisco has an extensive system of electric tramways, the car can be employed throughout the city, and will, it is said, to an extent supersede the use of hearse and carriages for funerals.

Books Received.—We have to acknowledge receipt of the following: "Induction Coils and Coil-Making," by F. C. Allsop (E. and F. N. Spon); "The Electric Transformation of Power," by Philip Atkinson, A.M., Ph.D. (Crosby Lockwood and Son); "The Inventions, Researches, and Writings of Nikola Tesla," by T. Commerford Martin (the *Electrical Engineer* of New York); "Electricity in the Service of Man," by R. Wormell, D.Sc., M.A., and revised and enlarged by R. Mullineux Walmsley, D.Sc.(Lon.), F.R.S.E. (Cassell and Co., Limited).

Huddersfield Electric Light Station.— With reference to the description of this station, given in our issue of the 26th ult., we are requested to publish the following statement concerning the efficiency of the plant: "Although the station has only been at work a few months, the results already attained (and which will no doubt in due course be published) are exceedingly satisfactory, the cost per unit supplied to the customer, as shown by carefully compiled returns, being considerably lower than any hitherto published."

Japan.—It appears that Japanese electrical engineers are devoting attention to the drawing up of elaborate plans for the utilisation of water power and the construction of electric railways. At Uwajima, Ehimé-Ken, it is proposed to construct an electric railway between that town and Nakamura, a distance of 50 miles, the Semba Falls in Kita-Uwa-gun to be utilised as the motive power. Another proposed line of electric railway is between Takidani, Kobe, and Yuamacho, a distance of 15 miles. In this case it is proposed to utilise the waterfalls in Arino-mura.

Electrically-Lighted Lifebuoys.—Some trials have just been made at Kiel on board the German war vessel "Wörth" with an electrically-lighted lifebuoy, the invention of Captain Melter. The buoy, according to *Industries*, was thrown overboard when the vessel was proceeding at a speed of about 16 knots. For a space of about 12 seconds it was lost in the eddy current caused by the twin screws of the vessel, but then reappeared. The new lifebuoy will be found useful at night time, and the experiments resulted so successfully that it is probable that it will be adopted generally in the German navy.

The Edison Lamp.—It appears from a recent decision of Judge Shipman, in the United States Circuit Court for Connecticut, that the introduction of an inert gas into the bulb of an incandescent lamp does not avoid the Edison lamp patent. The specific point at issue was the asking for an injunction by the Edison Company against the manufacturers of the "Novak" lamp, which was thought by many to not infringe the Edison patent, for the reason that bromine gas was introduced into the bulb. The Court held that the "Novak" lamp embodies the entire invention of Edison, and the manufacturer thereof should be enjoined.

Engineers and Shipbuilders.—The fifth general meeting of the North-East Coast Institution of Engineers and Shipbuilders will be held on Tuesday, the 13th inst., in the Physical Lecture Hall of the Durham College of Science, Newcastle. A discussion will take place on Mr. Frank Caws's paper, "On Certain Principles of Motion, as taught by the Pendulum, and as illustrated by the Resistance of Ships, and other bodies moving through fluids, together with a brief sketch of the Pendulum Speed-Power Meter." A paper will be read "On a New System of Construction for Large Vessels of Cellular Type," by Mr. William Bell.

Traction at West Hartlepool.—The Town Council this week discussed the report of the Works Committee. The chief feature of this was a recommendation of the sub-committee which visited Leeds to inspect the electric tramway to the effect that they found it to be working satisfactorily, and that the Council be recommended to approve of the system, to be laid down from a point commencing at the police station and continuing to the borough boundary, subject to the poles being erected on one side of the road only. Considerable discussion ensued as to the proposal regarding the poles, and an amendment referring this portion of the question back to the committee was carried.

The Phonograph Patent Action.—An action brought by the Edison-Bell Phonograph Corporation against Mr. G. A. Smith and Mr. Young has been decided. It was a patent case which has occupied the Court for a considerable time. The action was for damages and an injunction in respect of infringement by the defendants, G. A. Smith and J. L. Young, of a patent for improvements in connection with phonographs, taken out by Mr. Edison, and by him assigned to the plaintiff company. His Lordship last week gave judgment for the plaintiffs, with costs, and granted a certificate of the validity of the patent, and an injunction against the defendants. He added that he would subsequently give the reasons for his judgment.

The British Association.—The council of the British Association has confirmed the nomination of the following presidents of sections for the meeting at Oxford, the commencement of which has been fixed for August 8: Section A (mathematical and physical science), Prof. A. W. Rücker, F.R.S.; B (chemistry), Prof. N. B. Dixon, F.R.S.; C (geology), Mr. L. Fletcher, F.R.S.; D (biology), Prof. Bayley Balfour, F.R.S.; E (geography), Captain W. J. L. Wharton, F.R.S., hydrographer to the Admiralty; F (economic science and statistical), Prof. C. F. Bastable; G (mechanical science), Prof. A. B. W. Kennedy, F.R.S.; H (anthropology), Sir William Flower, K.C.B., F.R.S.; I (physiology), Prof. E. A. Schafer, F.R.S. The last is a new section resolved on at the Nottingham meeting of 1893.

Expiration of the Bell Telephone Patent.—The second fundamental Bell telephone patent expired at the end of January. The carbon transmitter is still protected to a great extent by fundamental patents of uncertain validity. Among these the Berliner patent of November 17, 1891, has become celebrated; its tenure of life is now the issue in a suit brought by the United States Government for its annulment. Then there is the Edison patent of May 3, 1892, of uncertain validity, owing to the English patent for the same invention, which expired before the American patent was granted. The fate of this patent will depend largely on a decision in a case now pending in which the same point is involved. The whole affair is quite complicated, and its complication appears greater when the quantity of minor patents held by the Bell Telephone Corporation are considered.

Gas Monopolies and Electric Lighting.—Disputes have arisen of late years between gas companies and municipalities on account of the violation by the latter of contracts entitling the companies to a monopoly. According to a correspondent of the *Times*, St.-Etienne and Montluçon were three years ago ordered by the Council of State to compensate the companies for allowing the introduction of the electric light. On the 2nd inst. the same

Digitized by Google

tribunal gave judgment in favour of a claim for the assessment of damages by the gas company of Argentan against the municipality. The latter had not only allowed an electric light company to lay down wires, but had allowed it the use of a site for its works. The judgment contains a recital that, whenever a gas company has been accorded a monopoly for any fixed period, compensating advantages have always been guaranteed to the local authorities in the shape of cheap rates or participation in profits.

Lighting in the Crystal Palace District.—Mr. George Offor, the managing director of the Crystal Palace District Electric Supply Company, has issued a pamphlet containing testimonials received from consumers during January concerning the efficiency and cheapness of the supply of light by the company. Mr. Offor directs special attention to the letter of Mr. J. S. Sellon, in whose opinion the indirect economies and the saving in health resulting from a pure atmosphere really dispose altogether of the quarterly accounts for the electricity, leaving the cost "not much greater than that of the light of the sun." The testimony of Messrs. Sydney Smith and Sons, after employing in their extensive establishment both gas and electricity, is that the cost of the latter is half as much again as gas, but with twice the light power. The company's mains are laid in various thoroughfares, where a constant supply of electricity, day and night, can be obtained at 8d. per Board of Trade unit, delivered by meter, which is given as equivalent to one farthing per hour for 8 c.p.

Telephony in Manchester.—The Parliamentary Sub-Committee of the Corporation have presented a report dealing mainly with the subject of telephone wires. The report contained a copy of a letter addressed to the Lord Mayor by the general manager of the National Telephone company, complaining that no answer had been received to the application made by the company to the Council for facilities to place certain of the company's wires underground. It was stated that there was grave danger, which was becoming accentuated by delay, of the dislocation of the telephone service. The general manager added that the necessary instructions had been given for reconstructing the company's telephone system in Manchester on the metallic circuit principle, by means of overhead wires. Having regard to this letter a motion has been adopted by the Corporation authorising the sub-committee to enter into direct communication with the National Telephone Company in regard to the laying down of underground wires within the city, and to report the result of such negotiations.

Testimonial to Principal Garnett.—In connection with the movement for the presentation to Principal Garnett of a testimonial from students of the Durham College of Science, Newcastle-on-Tyne, a preliminary meeting of subscribers was recently held in the college, Mr. G. H. Burkhardt, A.Sc., treasurer of the fund, in the chair. The chairman laid before the meeting the steps which had been taken to bring the movement before the notice of all past and present students, and stated the result of these efforts. It was agreed that as Dr. Garnett will remain principal of the college until June, when the present session ends, the subscription-list should remain open until Saturday, April 21. It was thought that in this way a large number of students, before whose notice the project had only quite recently been brought, would be afforded a better opportunity to subscribe. A resolution was also passed leaving the selection of the form of the testimonial to the committee, with a proviso that its numbers be increased by the addition of students from those sections which do not appear to be adequately represented at present. For this purpose meetings of the various sections will be held in the college at suitable times within the next two or three weeks. We understand that a full statement of the position will be laid before each of these meetings, so that every student may be brought closely into touch with the work of the organising committee. We may add that the individual subscription is limited to five shillings.

"Lockwood's Builder's and Contractor's Price-Book."—Certain portions only of "Lockwood's Builder's, Architect's, Contractor's, and Engineer's Price-Book for 1894," which has just been published by Messrs. Crosby Lockwood and Son, appeal directly to electrical engineers and contractors. The work forms a comprehensive handbook of the latest prices of every kind of material and labour in trades connected with building, including a large variety of the most recent information in all matters concerning these branches. The present edition has been rewritten, enlarged, and edited by Mr. Francis T. W. Miller, A.R.I.B.A. Of the sections dealing with electricity may be mentioned a short article on the supply of electricity, this being followed by particulars of output and price of dynamos, alternators, and accummulators made by different firms; of arc lamps, carbons, incandescent lamps, fittings, and accessories, electric bells, etc. The handbook also contains copies of the conditions under which the City of London Electric Lighting Company supplies electrical energy, and of the well-known rules of the Phœnix Fire Office for electric light and power installations. The "Price-Book" can be well recommended as a valuable work of reference.

The Prize for an Improved System of Traction.—In addition to the systems referred to in our last issue as competitors for the prize of £10,000 offered by the Metropolitan Traction Company for a railway equal to the trolley system, without overhead or other objectionable features, may be mentioned a method devised by Mr. William Lawrence, of the Lawrence Electric Company, New York. In this system a conduit of vitrified clay and a sectional trolley wire normally out of contact with the feed wire, and entirely dead except during the passage of a car, are used. The conductor sections are of copper wire 32ft. long, each soldered along the flange of a piece of angle iron of the same length, and of sufficient cross-section to be quite rigid when supported only at its extreme ends. At the end of each section is a watertight and airtight junction-box with a heavy rubber top through which projects a pin adapted to be screwed to the end of an angle-iron section and to support it in position. The lower end of this pin in the box is provided with copper brushes that make contact with a copper plate below when depressed. The weight of the section, however, is not great enough in itself to force it downward, and it is kept by the air pressure in the box, and by the elasticity of the rubber top, from completing the circuit except during the passage of the car. The feeder is wholly insulated and all connections are made within the boxes. The car carries a double trolley making contact with one section of conductor before that with the last is broken, in order to minimise the tendency to sparking. An experimental line on this system will shortly be demonstrated.

Private Installations at Maidstone.—A private installation of the electric light has recently been completed on the premises of Messrs. Richard Dann, of High-street, Maidstone. The generating plant comprises a "Taunton" 26-unit dynamo, wound as a shunt or compound, with a switch to open or close the series coil. It is driven by a "Trusty" gas-engine. There is a battery of 23 L-plate E.P.S. cells, connected in shunt with the machine in the usual way, excepting that some larger cells of three times the capacity have been fixed on the regulating switches, thus enabling the "heavy load" current to be put

Digitized by Google

through these regulating cells, and so check the E.M.F. in the lamp circuits and charge to their full charging capacity the main battery of cells during the lighting hours. By this arrangement the engine and dynamo can be run at full load, and consequently at high efficiency, for nearly the whole of the lighting hours, charge the batteries for two-thirds the time and discharge for one-third the time, and supply lamps during the daytime from the remaining charge. There are about 300 16-c.p. 100-volt lamps on the mains, and several arc lamps and large-power incandescents fixed in the showrooms and on other premises. Owing to the unequal distances of the consumers' premises from the generating station, it became necessary to transmit the current at graduated E.M.F.'s to make up for the loss in transmission through the mains. To do this economically a separate pair of mains was carried to each consumer, and a separate cell-regulating six-point switch arranged to each. The switchboard is also fitted with the usual measuring instruments and accessory switches and plugs, and safety cut-outs and devices. The installation was carried out by Mr. Chas. Rawlings, assisted by Messrs. T. Price and A. Clark.

Birkenhead.—The proceedings of the Finance Committee presented at a meeting of the Town Council on Wednesday contained a report by a special sub-committee with reference to the steps to be taken in regard to the carrying out of the provisions of the Birkenhead Electric Lighting Order, 1890. The sub-committee stated that they had, with a view to obtaining information as to the system of electric lighting best suited to the requirements of the borough, obtained reports on the subject from Dr. Hopkinson and Mr. J. N. Shoolbred. The sub-committee were of opinion that the time had arrived when the circumstances in connection with the steps to be taken under the Birkenhead order demanded that an electrical engineer should be appointed to advise the Corporation as to the details of the system of electrical illumination to be introduced. The sub-committee therefore recommended the appointment of Mr. J. N. Shoolbred. The sub-committee had also considered with Mr. Shoolbred the question of a suitable site upon which to erect the necessary central generating station, and they recommended that they should be authorised to select and purchase a site in a suitable locality as they might be advised by the electrical engineer. Alderman Deakin moved the adoption of the report, and said that some four or five years ago legislation was passed whereby companies and others undertaking electric lighting works were placed in a very favourable position. In Birkenhead, when they saw the powers which might be conferred by the Board of Trade by means of provisional orders, and when they saw several companies applying for those orders, they came to the conclusion that they ought themselves to apply for the order, and an application was accordingly made and granted. They had been told by the engineer that they could make a beginning with a capital of £14,000 or £15,000, which did not include the value of land or professional services. Although at first it might not be profitable, it was thought that a long time would not elapse before it would pay expenses. Mr. Gostenhofer seconded the motion, which was adopted with a slight modification concerning the site.

Vibration.—At the last meeting of the British Association, Mr. W. W. Beaumont read a paper on the automatic balance of reciprocating machinery, and on Wednesday last supplemented this with another paper read at the Society of Arts. The subject is extremely interesting, and points once more to the blindness of ordinary mankind. It would be difficult to determine how great progress has often been made by going backward. Let us explain. A certain result is often aimed at and obtained. In getting that result damaging opposition is overcome, and in the case of manufactures by-products are produced which for the nonce are thrown aside. By-and-by someone comes along, takes up these by-products, and shows that they are more valuable than the direct result; and we progress by going backward. Prof. Hughes told us how to make telephony practicable by taking advantage of bad contacts. Now Mr. Beaumont is telling us how to get rid of vibration by deliberately allowing it and using it to kill itself. Electrical engineers are greatly concerned in minimising vibration, and the last paragraph of this paper will appeal directly to them. It is as follows: "The fact that this wall moves is a proof that there is something connected with it that wants to move and we will not let it, or wants to move more than we will let it. Now, this is bad policy, and the lesson to be learned from it is that as we cannot stop the unbalanced thing from moving, we had better make our calculations afresh on the assumption that that fact must not be ignored, and that it must be allowed to move. It is no use trying to stop it, unless we give it something to expend its energy upon. We must let it move because we cannot help it, but we can help letting it move without taking toll. It is one of those 'forces in nature which we must direct for the use and convenience of man,' and in a general way it may be said that when a piece of mechanism wants to wobble, it is obviously either wrongly constructed, or if it is not and wants to wobble, then let it wobble, but make it wobble something you want wobbled. In most cases it will not wobble so much, and never so forcibly, if we don't try to stop its wobbling."

Utilisation of the Irish Sea Tides.—An article on the above subject, by Mr. W'r. Lodian, is published in the *Electrical Engineer* of New York of January 24. We extract the following: "The author states that in February last he concluded a series of hydrographic surveys on the Antrim coast of Ireland. He was specially detailed to report upon a project to connect Britain and Ireland by a land junction. It was pronounced practicable, but the question was asked: What is the use? The primary feature of the projected land junction will be its power-houses, and their use in the generation of electricity from the strong currents always prevailing in that part of the Irish Channel. The water power there running to waste is such that, if utilised, power and lighting could be supplied to the districts for hundreds of miles around. Two power-houses would be ample; one for supplying the Scotch side, the other for the Irish side, and a railroad would run along the isthmus from Cantire to Antrim. While in the present state of the project, it would be 'too much to reveal too much,' a few extracts may be made from the official specifications, which will show what the constructing engineer proposes to do, and how. In a direct line north-west of London, about 365 miles, and north of Dublin about 126 miles, is the narrow passage between Ireland and Scotland, at the Mull of Cantire The Gulf Stream supplying the continuous current flows from the North Sea into the Irish Sea in volumes of water estimated at many cubic miles daily. The waterway between the headland of Cantire in Scotland and Torhead in Ireland is 15 miles wide, 474ft. deep at mid-current, but much shallower towards either shore. This is the position selected as offering the best engineering facilities for the creation of an isthmus as shown on the chart. The high bluffs of Cantire and the still higher land comprising mounts Clady, Escart, and Carnlea near the Irish coast, from 900ft. to 1,200ft. high, offer facilities for gravitating

Digitized by Google

the materials requisite to form the isthmus between the opposite shores. The superficial extent of land required to form the isthmus would be a little more than a square mile, of the average width and depth of 100 yards. There are no engineering difficulties in the way to prevent the immediate commencement of the undertaking, if favoured by national approval and commercial enterprise. The cost of creating the isthmus would be about two million pounds sterling, and the time it would occupy would be about three years. To maintain a passage of ships to and from the North Sea to the Irish Sea, the Canal of Crinan might be enlarged and another cut through the Isthmus of Tarbert."

The Faulty Wiring of Vessels.—The *Pall Mall Gazette* has followed up its article on "A Needless Ocean Danger," of which we gave an abstract last week, by reports of two interviews with persons interested. The first was with Captain Froud, lieutenant R.N.R., the secretary of the Shipmasters' Society. Captain Froud contends that the existing condition of defective wiring is chiefly due to the absence of supervision. He agrees that a deck officer and an engineer of each crew should be the certified possessors of certain electrical knowledge, and that for this remuneration should be commensurate. Much good, he opines, would be done if Lloyd's surveyors inspected the electrical arrangements, or retained specialists to do so, and withheld their highest mark in cases where there were unnecessary risks. The second interview took place with an electrical expert, who said that it was extraordinary that the system of putting up installations on board ship had got in a vicious state. Personally, he did not blame the contractors. His experience was that the contractors, in many cases, had put in as good material and as good work as they could possibly afford to do for the price they had been paid. Continuing, he remarked: "The whole system has got into a vicious condition. Contracts are put up to tender, and go to the lowest, with practically no specifications whatever except the contractor's own. Then there is no supervision of the work in many cases by any independent consulting engineer, and if the work complies with certain tests as to what the dynamo can do and so on, the job is passed as a matter of course." Asked as to what was the possible saving to the contractor between good and indifferent work, he replied that it might be 50 per cent. He observed further: "I do not think good firms can do the work in the way that, in my opinion, it ought to be done at the prevailing prices. As with all such matters, if a fair price be paid, and a consulting engineer retained to supervise, it would be a solution of the whole matter. Any work might get into the same condition that this electric lighting of ships has got into with unlimited competition without supervision. Let the specifications be written out by competent electrical engineers, who should take into consideration, of course, as they do with buildings, the fire risk aspect as well as that of the illumination. Then let the contractors tender upon those specifications, and then if the work be subjected to supervision during its progress, and if the contractors be paid on the certificate of the electrical engineer on the completion of the work, we should get the same satisfactory condition of affairs with regard to ships as we have already obtained, by similar means, with regard to buildings. That would be a much better way than by any Government interference, for I do not believe in the incessant invoking of Government."

The Electrolysis of Sea-Water.—In the course of a communication to the *Lancet*, a correspondent at Havre says: "The town of Havre determined to give M. Hermite every facility to carry out his process, and at first the experiments caused considerable enthusiasm. Buoyant hopes were entertained that a solution had been found for the difficulties which beset this town. Havre, as I described when dealing with the cholera epidemic of 1892, drains its refuse into the gutter. When the water that conveyed the household slops and also the sewage from the closets had been charged with chlorine, there was not only an absence of bad odour, but the gutters, always more or less black and soiled, were beautifully bleached. The kerb and flagstones became white, as if they had just left the quarry. The effect was drastic, and loud were the praises raised. The municipality of Havre, however, appointed a technical commission to enquire into the process. The following is an abstract of the description given by M. Hermite of the works he established at Havre. These were situated at the Pont d'Angoulême, where the cost of labour, fuel, etc., amounted to 70f. a day. In England, where labour is not so cheap, this would have cost £3, or probably £3. 3s., per day. There were two steam-engines of 35 h.p., and two complete and separate electrolysing machines, each carrying two electrolysers. Three rotary pumps propelled the liquid disinfectant up to a reservoir 12 metres above the works. There was a rotary pump to draw up the sea-water and discharge it into the electrolysing tanks, and another pump to fill the reservoirs with electrolysed water. From these reservoirs the water could be delivered to the houses where the experiments were made. Under normal conditions each electrolyser should work as follows: 1,200 amperes × 5·5 volts = 6,600 watts; $\frac{6,600\text{ w}}{736\text{ w}} = 8{\cdot}96$ electric horse-power; this + 20 per cent. = 10·75 mechanical horse-power. To this should be added the necessary force for the circulation and transmission pump, which gives a maximum of 12 h.p. for one electrolyser, or 48 h.p. for the four electrolysers Under these conditions the normal production would be one kilogramme of chlorine (*chlore*) per hour per electrolyser, and this would give two cubic metres of liquid containing 0·5 gramme of chlorine per litre per hour, or four cubic metres of the solution at 0·25 gramme of chlorine per litre per hour. But M. Hermite stated to the municipality of Havre that the velocity of the machinery was insufficient, and that the average intensity of the electric current for each of the two electrolysers was 925 amperes × 11·25 volts = $\frac{10,406\text{ w}}{736\text{ w}} = 14$ electric horse-power; this + 20 per cent. = 16·8 mechanical horse-power. Adding to this the power for the pumps, the total reached was 18 h.p. for each of the two electrolysers. The installation produced on an average one gramme of chlorine per hour per ampere, or 925 grammes of chlorine per electrolyser, or, for the four electrolysers, 925 × 4 = 3,700 kilogrammes of chlorine per hour. They were therefore able to produce one cubic metre of liquid containing 0 5 gramme of chlorine per litre in about eight minutes, and at the rate of 0·25 gramme of chlorine in four minutes. In the Rue d'Edreville a house with 35 inhabitants was supplied for the closets with 180 litres per 24 hours, or about five litres per inhabitant. In the Rue Fontaine a house with 30 inhabitants was supplied with 350 litres, or 11·5 litres per inhabitant, and there were 150 litres for some automatic flush-tanks, or 500 litres in all—that is, an average of 16·5 litres per inhabitant. M. Hermite thinks that there should be 20 litres per head at 0·25 gramme of chlorine per litre. He stated that he was able to guarantee a supply of 1 kilogramme of chlorine per hour per electrolyser for a motive power of 12 h.p., which would be equivalent to 48 cubic metres of the disinfectant in the 24 hours at a strength of 0·5 gramme of chlorine per litre, or, as he seemed to prefer, 96 cubic metres at 0·25 gramme per litre."

THE KINGSTON CORPORATION ELECTRIC LIGHTING STATION.

The idea has for some time been prevalent amongst many that an electric lighting central supply station owned and operated by the local authority can only be established with success, from an economical standpoint, in districts of considerable size, and also very thickly populated—that is, in the present state of the electrical arts, only large towns and cities are practically justified in taking up the supply of electric energy for public or private purposes.

Instances, however, of highly successful stations even equipped on a small scale are by no means wanting; and we need go no further from London than Kingston-on-Thames to find a supply station of good design and carefully thought-out construction.

It is situated close to the gasworks, between them and the South-Western Railway, being also only a few yards from the River Thames, and occupies practically a portion of the Kingston Corporation Drainage and Streets Committee's land. Being a municipal undertaking, it has throughout been in the hands of the borough surveyor, Major Macaulay, more especially as regards the buildings, the chief character of which is a neat substantiality.

The main block itself is of an irregular oblong shape, in plan, as may be seen from the annexed engraving; the main front and sides—of red brick—are, of course, permanent, but in the rear the outer wall is more or less of a temporary nature, so that extensions may conveniently be made when more energy is required to satisfy public demands for light and power. At present there are seven sets of steam-dynamos erected, space being left in the building, as it stands, for one large set—of 150 h.p.—and another boiler.

Sectional Elevation of Buildings—Kingston.

The front entrance of the building opens into a hallway and a suite of offices and stores on the ground and first floors: passing thence through a door, one enters the engine-room, a building about 40ft. square, with a height of 23ft. Windows on the one side give all necessary light, though, if required, still more can be obtained by opening up large doorways in the back wall, through which all the heavy plant is introduced. A five ton overhead hand traveller, worked by chain, has been erected for this latter purpose, and for lifting heavy parts of engines or dynamos at any time. A louvre ventilator in the roof serves to carry off the heat and steam that may arise.

The main steam supply piping is brought in from the adjoining boiler-house, so as to form a complete ring round one half of the engine-room: branches are taken from this to the different engines, and large stop-valves allow them to be operated from one or other half ring as may be desired. In the space enclosed by the ring, between the centre line and side wall, are erected two 75-h.p. steam-dynamo sets. These each comprise one of Belliss's self-lubricating compound vertical engines, driving direct a Siemens alternator with an output of 24 amperes at 2,100 volts and a speed of 460 revolutions per minute. These machines are employed for the incandescent lighting; but, of course, their full output is not as yet taken up, though very satisfactory progress is being made with installations in shops and private houses.

On the other side of the engine-room there are erected, first, two 30-h.p. engines of similar type to the above, each coupled up direct to a Siemens continuous-current machine, for arc lighting. At present there are only 36 street lights in use, in two series of 18 each, so that one of these machines is practically spare or held in reserve, the other being fully able to take the whole load. They each give 20 amperes at 950 volts, and run at a speed of 550 revolutions per minute.

Next to these, there come two 25-h.p. engines, driving direct a couple of shunt-wound continuous-current machines by Siemens, which are used to excite the fields of the large alternators, and can also supply current for the lamps erected throughout the station itself. These give 160 amperes each at 105 volts, the speed being the same as those last mentioned. Either machine is sufficient for the total work required at present, and there is consequently ample reserve power.

The remaining set consists of a 40-h.p. engine coupled directly to a Siemens alternator giving an output of 12 amperes at 2,100 volts, at a speed of 580 revolutions. This machine serves to take the light loads in the daytime, etc., and until the demand increases, it also obviates the necessity of running both the large alternators simultaneously. In this connection, of course, it must be borne in mind that the whole station has only been at work for a couple of months or so, and the number of consumers therefore cannot be expected to increase so rapidly as at once to take up the whole output. The question of reserve power has been studied so carefully that the capital outlay on surplus plant must have been a minimum for a station of this character, and the arrangement of units adopted might be followed with advantage by other local authorities who fear the inefficiencies of light load in generating plant of large output.

Adjoining the engine-room is a boiler-house, measuring 50ft. by 40ft., with a height of 20ft. This contains at present a couple of large horizontal double-flued multitubular boilers, constructed by Messrs. Belliss and Co., with room for a third alongside. These boilers are each 22ft. 6in. long, with a diameter of 7ft. 2in., and work at a pressure of 150lb. to the square inch; they are fitted with Bennis's mechanical stokers, and besides the usual mountings have an isolating stop-valve, so that any one may be cut off from the steam supply pipe when desirable. Their flues join at right angles into a main smokeway at the back, underground, which is connected to a Green's economiser, with pivoted dampers and a by-pass into the chimney flue. This latter runs underground along the outside of the boiler-house front wall, terminating in the base of a large brick chimney stack.

In the boiler-house there is found room for a very complete system of surface condensing apparatus: this includes a horizontal surface condenser with a total cooling surface of some 1,000 square feet, operated by a double-acting vertical air-pump. A centrifugal pump, driven by a small vertical single-cylinder engine, serves to circulate the cooling water through the condenser; the water is obtained

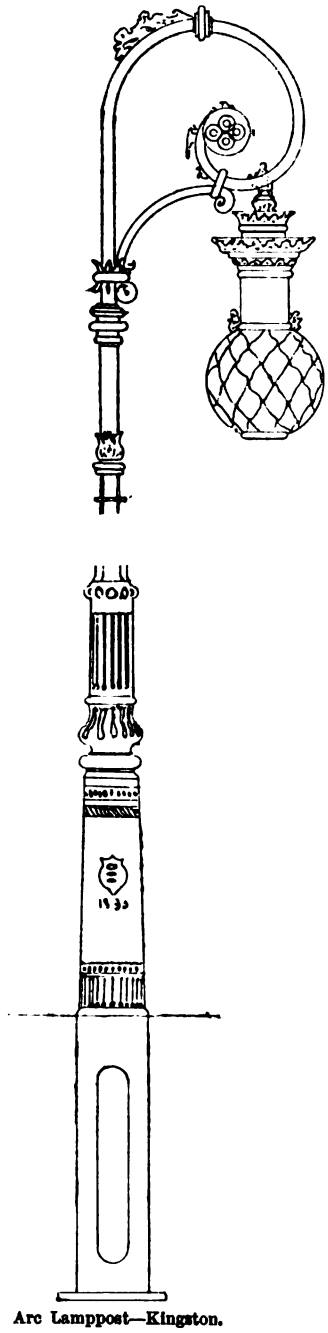
from a cold-well sunk underneath the boiler-room floor and connected with the River Thames by means of a pipe. An inexhaustible supply is thus obtained.

Fuel is brought into the boiler-house at the rear, and suitable provision for storing and elevating it into the stoker hoppers will be made as soon as possible. A pair of small vertical engines are erected on framing above the cold-well for the purpose of driving the stokers, and also the scrapers on the pipes of the economiser.

The outside circuits from the station are all on the Siemens concentric cable system. A very elaborate and well-designed switchboard—occupying almost half one side of the engine-room—serves to carry all the regulating switches, resistances,



Arc Lamppost—Kingston.

instruments, etc., required in a central station. As stated, the high-tension pressure is maintained at 2,100 volts, which is reduced for interior circuits to 105 volts, the frequency being 77 periods per second. The alternators are worked absolutely in parallel, and can indeed be worked in no other way.

The engineer in charge of the station is Mr. J. E. Edgcome, A.M.I.M.E., A.M.I.E.E., who has been appointed to the position of borough electrical engineer. This gentleman represented, during the erection of the station, Mr. A. H. Preece, the consulting engineer to the Corporation. The buildings were erected by Messrs. Allen and Sons, of Kilburn, and the electrical equipment throughout was in the hands of Messrs. Siemens Bros. and Co., Limited,

as contractors, to whom much credit is due, the generating and distributing plant having worked with satisfaction in all respects.

In the town of Kingston, of course the wiring of shops, houses, and public buildings, etc., has been in the hands of installation contractors—chief among whom may be mentioned Messrs. New and Mayne, of River Front, Kingston, who have put up about 500 incandescent lamps in various quarters, including the County Buildings, and the old-established Ceres Ironworks, Limited, of Kingston—who have also carried out a number of installations in shops, etc., involving several hundred lamps. The latter firm has, moreover, executed the order for arc lamp-posts required by the Corporation for street-lighting, their iron foundry department being capable of dealing with much heavier castings even than these. We illustrate the design and type of post adopted.

INSULATION.

(Continued from page 103.)

There seems to be no definite rule respecting the state of insulation resistance for electric light circuits, which is to be regretted. Each electric supply company requires a different standard, the same with the insurance companies; and there is a great variety in the way of expressing it, some requiring an insulation resistance a dozen times more than others, so that these rules are to a great degree very arbitrary. When treating of insulation resistance, it must be remembered that the greater part of the leakage is caused by the "fittings"—such as fuses,

Digitized by Google

switches, lampholders, etc.; these harbour moisture, and so promote surface leakage: this is why it makes such a difference whether the insulation is tested on a dry or a wet day. The most general practical formula for insulation resistance is of the form—

Rule (I.) $$R_i = K \frac{E}{C},$$

where K is some constant the value of which differs according to different authorities; and whatever this value of K may be, the result is that the insulation resistance must, according to the above formula, be some function of the resistance of the conducting circuit.

With a fixed potential difference, E, the resistance of the circuit determines the useful current in the conductors, while the insulation resistance determines the leakage current; and, as the insulation resistance is K times the circuit resistance, hence $\frac{1}{K}$ measures the leakage current as the fractional part of the useful current. For example, let the pressure of the circuit be 110 volts and the current, say, 275 amperes, supplying about 500 lamps of 16 c.p.; then, if a numerical value of 10,000 be given to the constant K, we shall have—

$$R_i = \frac{10{,}000 \times 110}{275} = 4{,}000 \text{ ohms.}$$

Hence R_i, the insulation resistance, works out to 4,000 ohms, and as K has a value of 10,000, therefore the leakage current will be $\frac{1}{K} = \frac{1}{10000}$ part of the lamp current, or or in this case $\frac{275}{10000}$, or, roughly, $\frac{1}{40}$ of an ampere.

The above-mentioned formula is probably the simplest and most commendable to use, because it defines at once the ratio between the leakage current and the total current in practical work. If this is known, it tells us pretty well the condition of the insulation.

With regard to the value to be given to K, the value ranges from 5,000 to 50,000, or even 100,000. Instead of judging of the insulation resistance by its leakage current, it is a good rule to specify so many megohms as a constant and then to divide by the number of 16-c.p. lamps there are on the circuit. The rule then being

Rule (II.) $$R_i = K \div \text{lamps.}$$

The constant, K, in use amongst electric supply companies for 100-volt circuits varies from 100 to 10 megohms. For example, take a circuit at 100 volts, having, say, 1,000 lamps of 16 c.p. in parallel, and let the constant be 50 megohms, then the insulation resistance will be

$$R_i = 50{,}000{,}000 \div 1{,}000 = 50{,}000 \text{ ohms.}$$

Upon working out, this resistance will be found to correspond with a leakage current of $\frac{1}{300000}$ part of the total current.

Several of the leading electric supply companies adopt this rule, giving various values to K. Thus, the City of London require the high value of 75 megohms, the Bradford Corporation are satisfied with 10 megohms, while the Glasgow Corporation demand 60 megohms. Amongst those who prefer the first rule, that of stating the leakage current as a fractional part of the useful current, are several insurance companies, who have settled on $\frac{1}{200000}$ part of the current, while the theatre restrictions made by the London County Council allow a leakage of $\frac{1}{150000}$ part.

It is customary to double the constant when alternating currents are used, because the maximum value of the E.M.F. is higher than the working voltage, which, as before mentioned, is expressed by $\sqrt{\text{mean square}}$. A third rule is a mixture of the two previous ones, and consists in multiplying the constant K by the working voltage, whatever this may happen to be, and dividing by the number of lamps of 16 c.p. that are wired. This rule thus takes the form—

Rule (III.) $$R_i = K \frac{E}{N}.$$

Take a plant running, say, 4,000 lamps at 110 volts pressure, putting K as 80,000, we obtain

$$R_i = 80{,}000 \times \frac{110}{4{,}000} = 2{,}200 \text{ ohms.}$$

Tabulation 32 gives the insulation resistance worked out from Rule (I.) for various currents from 10 to 2,000, and also at various voltages, the standard for K being put at 50,000, so that the figures given are obtained from the formula $R_i = 50{,}000 \frac{E}{C}$, and thus show what the insulation resistance in each case should be, so that the leakage current will not exceed $\frac{1}{30000}$ part of the total current. This standard may be taken as one that will give most satisfactory insulation.

TABULATION 32.

Maximum current.	Working pressure of circuit in volts			
	110	80	65	50
10	550,000	400,000	325,000	25,000
30	183,330	133,330	108,330	8,330
60	91,700	65,000	54,166	4,166
100	55,000	40,000	32,500	2,500

(To be continued.)

THEORY OF THE RESISTANCE OF A STRANDED CONDUCTOR.

BY W. H. EVERETT.

(Concluded from page 123.)

It was shown in the first part of this paper that the resistance of a stranded conductor may be regarded as consisting of the resistances of the different layers in parallel. We may return, then, to the case of a single layer, and it will be found more convenient generally to consider conductivity rather than resistance.

The conductivity of a layer when all its wires are insulated from one another, being taken as unity, its actual conductivity was proved to be

$$1 + \frac{4}{\pi} \cdot \frac{\rho}{r_1 + r_2} \tan^2 \alpha;$$

where ρ = specific resistance;
r_1 = contact-resistance per unit length;
r_2 = resistance across a wire between its two contact-surfaces per unit length;
α = angle between a wire and the direction of the axis of the helix.

In the above expression ρ and α may be supposed given, and we have now to see what we know about r_1 and r_2.

The contact-resistance depends, of course, on the area and nature of the surfaces in contact. If we make the supposition that the distortion at these surfaces remains similar when the gauge of the wire is varied, then the contact-resistance will vary inversely as the diameter of the wire. It is probably less important than the cross-resistance, which, on the same supposition, will be independent of the diameter of the wire.

This cross-resistance is the resistance between two narrow planes of unit length, approximately at opposite ends of a diametral plane of a cylindrical wire; or, taking a cross-section of the wire, between A B and C D (see Fig. 4). Let semi-circles be drawn on A B and C D, representing semi-cylinders in section; then if these semi-cylinders were equipotential surfaces, the whole resistance could be considered as made up of three resistances in series—namely, the resistance between these two surfaces and the resistance across two semi-cylinders. The actual resistance cannot be very different from this. Writing d for the diameter of the wire and $2b$ for the width of the surface of contact, the first-mentioned resistance can be shown to be $\frac{2\rho}{\pi} \log_e \frac{d}{b}$. The sum of the resistances of the two semi-cylinders is, roughly, $\frac{\rho}{2}$. Hence the total

Digitized by Google

cross-resistance per unit length is approximately

$$\rho\left(\frac{2}{\pi}\log\frac{d}{b}+\tfrac{1}{2}\right).$$

Variation in the width of the contact-surface does not greatly affect the value of the cross-resistance, as is shown by the annexed table:

Diameter of wire / Width of contact	Cross-resistance (r_2). (Approx.)
5	2ρ
50	$3\frac{1}{2}\rho$
500	5ρ

Now the increase of conductivity owing to cross-current was proved to be

$$\frac{4}{\pi}\cdot\frac{\rho}{r_1+r_2}\tan^2\alpha.$$

Putting $r_1=0$, and $r_2=2\rho$, we find that the increase can hardly be greater than $\frac{2}{3}\tan^2\alpha$.

If the wires were straight, instead of being helical, the increase in conductivity would be $(\sec\alpha-1)$, or $\frac{1}{2}\tan^2\alpha$, α being small. Hence the conductivity of any layer would be nearly independent of α, and equal to that of a layer of straight wires, if

$$\frac{4}{\pi}\cdot\frac{\rho}{r_1+r_2}=\tfrac{1}{2};$$

that is, if $r_1+r_2=2{\cdot}6\,\rho$.

Assuming contact-resistance to be negligible, this would correspond to a width of contact-surface amounting to about one-twelfth of the diameter of a wire. This width is not likely to be exceeded in ordinary cables, and we should therefore expect that their resistance will be greater than if they were made of straight wires.

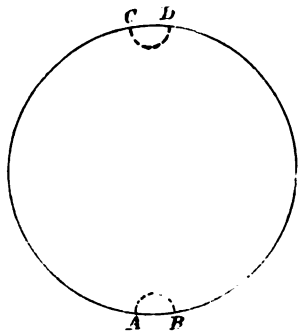

FIG. 4.

I am indebted to the Fowler-Waring Cables Company, the Silvertown India Rubber Company, and to Messrs. Siemens for information on the subject, and it would seem that the conductivity of a cable of n wires is not much less than the conductivity of n straight wires equal in length to the cable; corresponding to a width of contact amounting to perhaps $\frac{1}{50}$ or $\frac{1}{100}$ of the diameter of a wire. In the case of a layer for which $\alpha = 12\frac{1}{2}$deg., and therefore $\tan^2\alpha = {\cdot}05$, we should then get an increase of conductivity by cross-current of something like 2 per cent.

If the wires in a layer were compressed into a solid bar its conductivity would be $1+\tan^2\alpha$, the conductivity with insulated wires being taken as 1. For the length is decreased in the ratio $1/\sec\alpha$, and the area is increased in the ratio $\sec\alpha/1$. Hence the conductivity is increased in the ratio $\sec^2\alpha/1$. The increase is therefore $\tan^2\alpha$, or double what it is with straight wires.

We shall now obtain this result in an entirely different way, at the same time corroborating the fundamental expression for the increase of conductivity by cross-current. Suppose we have a layer of approximately square wires instead of round. The expression for the increase of conductivity in this case is easily found to be

$$\frac{\rho}{r_1+r_2}\tan^2\alpha,$$

where r_1 and r_2 relate to the square wires. The cross-resistance per unit length, r_2, now becomes equal to ρ. If the wires are compressed into a solid mass, r_1 becomes zero, and the expression becomes simply $\tan^2\alpha$, as before.

I had hoped to learn something more about the actual increase of conductivity by cross-current from an examination of the resistances given in cable-lists; but I find that they are practically useless for this special purpose, at least those I have so far seen. In some, the resistances are given only to two figures; in others, the resistances given would be, in many cases, too low if the weights of the conductors and the resistances and weights of the wires composing them are taken as accurate. Indeed, in the case of some cables the data are absolutely incompatible, for they lead to the result that the resistances of the cables are less than if the wires were compressed into solid bars of the same length and weight. This discrepancy is, perhaps, owing to the use in the cables of copper of higher conductivity than that on which the data for single wires are based. For our purpose it would almost be necessary to test single wires taken from actual cables, in order to obtain accurate data for comparison.

INSTITUTION OF ELECTRICAL ENGINEERS, Feb. 8.

Mr. ALEX. SIEMENS, President, in the chair.

At last night's meeting of the Institution the following candidates were balloted for:

Foreign Member.—Ernst Danielson, Allmänna Svenska Elektriska Aktiebolaget, Vesteras, Sweden.

Members.—The Marquis of Salisbury, K.G., F.R.S., &c., Hatfield House, Herts.; Benjamin Hillier Antill, Park House, Wallington, Surrey.

Associates.—Walter McLellan Arnot, City of London Lighting Company, Bankside, S.E.; Sidney Crouch, care of J. H. Holmes and Co., Oriel-chambers, Water-street, Liverpool; John R. Dobson, Brompton, Northallerton; Augustus Treyer Evans, 28, Bridge-street, Newport, Mon.; Oswin G. E. Hansom, Corporation Electric Light Works, Bristol; Alphonse Lucien Legros, 57, Brook-green, Hammersmith; J. Joseph Arthur Montealegre, 30, Queen's-gate-gardens, London; Percy W. Northey, the Richmond Electric Light and Power Company, Limited, Central Station, Richmond, Surrey; Henry Herbert Reynolds, Chesterfield, Hamilton-road, Ealing; William Gould Rhodes, Central Institution, Exhibition-road, S.W.; Charles Turner, Woking Electric Supply Company, Limited, Woking; Miles Walker, 102, Chetwynd-road, London, N.W.; James Whitcher, 14, Orde-Hall-street, Bloomsbury, W.C.

Students.—Frederic John Bakewell, 6, Gower-street, W.C.; Robert Birkett, Faraday House, Charing Cross-road, W.C.; Alfred Brown Blakey, 26, Dorothy-road, Clapham Junction, S.W.; Frank William Bowden, 9, Filey-avenue, Stamford Hill, N.; Alfred C. Eborall, 11, Queen's-road, Chelsea, S.W.; Edward Ernest Hoadley, Rochester-avenue, Rochester; George Reginald James Parkinson, Faraday House, Charing Cross-road, W.C.; John J. Pease, University College, Bristol; George H. Starr, 9, Halsey House, Red Lion-square, W.C.; Cecil L. Sumpter, 88, Netherwood-road, West Kensington Park, S.W.; Adolf Schoder, 121, Lansdowne-place, Brighton; Arthur Percy Strohmenger, 4, Tollington-place, Holloway, N; Frank Twyman, Victoria-road, Canterbury; Charles Yatman, University College, Bristol.

The following paper was then read:

SOME NOTES ON THE ELECTRIC LIGHTING OF THE CITY OF LONDON.

BY MAJOR-GENERAL WEBBER, R.E., C.B.

To the industry generally the history of the inception and of what led up to the accomplishment of the public lighting of the streets of that part of the Metropolis known as the City of London may have, for several reasons, a special interest and be worthy of record. By those who may not already know it, it should be understood that the Commissioners of Sewers hold a similar position and have similar powers to those that were possessed by the Metropolitan Board of Works and by the London vestries before the London County Council came into existence; in fact, they are the local authority, possessing jurisdiction distinct from that of the Corporation, the Common Council, the Bridge House Committee, and such bodies; having the direction and control of expenditure on works, for which purposes their engineer and surveyor is Mr. William Haywood, C.E., a gentleman distinguished no less as a colonel of Volunteers, late and for many years commanding the 1st London Rifle Volunteers,* than as an engineer.

I think there is a good deal in which the question of what led up to the lighting of the City by electricity so much differs from ordinary cases, that a slight sketch of its history—which has never, I believe, been published—is not out of place on the present occasion. The City is at the head of our municipal institutions, both as regards antiquity, wealth, and organisation. From an Imperial

* Colonel Haywood joined the corps in 1859 as a private, and rose through each rank to be lieutenant-colonel in 1876, and retired from that position in 1882.

Digitized by Google

point of view it is regarded as the heart of the commerce of the world. In respect to public lighting by electricity, I believe I can show that it also has taken the lead. In 1878, when the municipality of Paris celebrated the international exhibition of that year by lighting the Avenue de l'Opera with Jablochkoff lamps, run with Gramme machines by the Société Générale d'Electricité, Mr. William Bassingham, deputy-chairman, and Colonel Haywood, engineer of the Commissioners of Sewers, severally reported to the Streets Committee in such detail, and in such terms, as to ensure the question never being dropped until the accomplishment of the results which we can nightly witness at the present time.*

It is nearly 15 years since the date of those reports—years that have been momentous to all of us electrical engineers. Colonel Haywood's report could not have dealt more exhaustively with the question, subject to the difference in knowledge at the present day, than if it was now to be compiled. He pointed out that no section of the Metropolis was more interested than the City in obtaining an efficient illuminant, for that within its boundaries the Gaslight and Coke Company then collected a rental of £370,000 per annum. No doubt that example of street-lighting in Paris induced the Commissioners to take up the subject. The 64 electric lamps in a thoroughfare 980 yards in length, placed 30 yards apart on alternate sides, were said to give a nominal candle-power of 20 times that of the 300 gas lamps previously used, allowing that one Jablochkoff candle gave 100 times as much light as a gas-burner using 12-candle gas at 5ft. an hour. The cost price of these lamps (estimated then at 6d. an hour, as they were extinguished at midnight) was £50 a year each, which, for 64 lamps, came to £3,200 a year, as against the cost of the gas lighting during the same hours, which came to £1,200 a year at five centimes per gas lamp an hour. Colonel Haywood at that time considered that the avenue was lighted "vastly in excess of all reasonable requirements"; and although he went no further than stating that in his opinion there were places in the City—such as by King William's Statue, in front of the Mansion House, and in the circuses—where the convenience of the large traffic "might justify the expense of employing the electric light during the busiest hours of darkness," he nevertheless recommended the Commissioners, "that as early as possible an ample experiment be made by lighting with electricity during the winter months of 1878 one or more of the public thoroughfares within their jurisdiction." In consequence, in November, 1878, the same company commenced lighting the Holborn-viaduct with 16 Jablochkoff lamps, placed about 110ft. apart. They were run from sunset till midnight, replacing 86 gas lamps.†

The results arrived at after three winter months' work were that, while only doubling the light (allowing a loss of 50 per cent. with the globes) of the 86 gas lamps, the cost—namely, 5·73d. per hour—of 16 Jablochkoff lamps was four times that of gas at ½d. an hour. The discouragement produced by this experiment only continued for one year, and in the spring of 1880 the Commissioners (at the instigation of several members whose names have since been connected with improvements in lighting the City) again decided to renew experiments on a more extended scale by lighting (see streets shaded black on map, Plan No. 1) New Bridge-street, Queen Victoria-street, Queen-street and Queen-street-place, King William-street to the Bank, Poultry, Cheapside, St. Paul's-churchyard, Ludgate-hill, New Bridge-street, and the bridge. The thoroughfares in which the trials were to be made were divided into three districts, and out of six competitors who tendered in October, 1880, the following were selected, and the year's work lasted from April 1, 1881, to April 1, 1882: The Blackfriars Bridge district to the Brush Company; the Southwark Bridge district to the Electric Light Power Generator Company (Lontin system); the London Bridge district to Messrs. Siemens. Colonel Haywood reported in June, 1882, that, allowing 50 per cent. of loss through the use of globes in the several districts, the increased light afforded and the cost of the same under the tenders, in proportion to the gas, were:

	Increased light.	Relative cost.
No. 1 (Brush)	15	About the same.
No. 2 (Lontin)	14	Twice.
No. 3 (Siemens)	13½	3½.

Thus the City of London has taken the lead in making a practical experiment on a large scale.‡

The encouragement afforded by the results may be estimated by the following: (*a*) The Commissioners decided to experiment again in four additional areas and, calling for tenders, received, in May, 1882, offers from eight firms. In one tender only was the question raised of supplying light for private consumption. (*b*) Messrs. Siemens's offer to continue lighting No. 3 district at £3,600 a year, being an advance of £1,330 on their original contract, was declined, and that firm retired from the City. (*c*) An arrangement with the Brush Company to continue for another year lighting No. 3 district at a cost of £800 per annum was made.

But, as we all know, the Electric Lighting Act of 1882, which obtained the Royal consent and became law in that year appeared, and with it a flood of applications for provisional orders and licenses, three of which covered the area of the City, and obliged the Commissioners to hold their hands and consider the position in which the Act placed them, after having already had the subject in hand for nearly four years. In November, 1882, the Streets Committee of the Commissioners of Sewers consulted Mr. Preece, and I shall take this opportunity to remind him of a statement he then made, and has since repeated on the subject, in which, I am happy to be able to say, he showed an accuracy of foresight in which later experience has fully supported him. At that date he wrote: "I know of no branch of engineering where more forethought is necessary to calculate all the contingencies likely to be met with than a system designed to illuminate a large city like that of London." Meantime, an experiment with public lighting by incandescent lamps had been in progress. In April, 1882, the Edison Company commenced an experiment with that means of illumination on the Holborn-viaduct for a length of 466 yards, upon which Colonel Haywood reported after a 12 months' run. Ninety-two 16-c.p. incandescent lamps replaced the gas-burners in the existing street lanterns, 86 14-c.p. gas batswing burners being displaced. The result in light and cost was that the electric lighting contractors gave 1¼ times the light at the same price as gas—namely, £4. 10s. 4d. per burner per annum. That this experiment led to but negative results we all know. If it showed anything, it was that the substitution of an incandescent lamp in the ordinary street lantern for the lambent flame of a gas jet, so that the incandescent filament is directly visible, is a very poor and unintelligent application of the electric light, and puts it in a position in which it is at a great disadvantage in comparison with gas. I believe that the incandescent lamp for public lighting purposes never quite recovered from the results of that experiment. The City was one of the earliest areas upon which the electric light manufacturing companies set their eyes. Hardly had the 1882 Act become law when, as I have said, three companies commenced applications for provisional orders. As still now occurs, the local authority took alarm, and began to investigate the subject for themselves. Most complete reports as to the law, engineering, and science of the question were made by Mr. Baylis, Colonel Haywood, and Mr. Preece. These gentlemen may be said to have been amongst the very first to compile information for a local authority on the subject of electric lighting; and, although 10 years have passed, the terms they used, conclusions arrived at, and recommendations made, differ very little from those that have since and up to this date been, and are being, laid before similar governing bodies for their information and guidance.

The general tenor of the recommendations made in 1883, especially by Mr. Preece, were that the Commissioners ought to obtain their own provisional order or license and, either by contractors or by their own officers, to carry out the undertaking for themselves, both for public or private supply. The consequence was that in March, 1883, the Commissioners decided to apply to the Board of Trade for the necessary license, under the Act of 1882, for the whole city having in its terms a compulsory area of a limited size, and to oppose all other applications for provisional orders or licenses under the Act of 1882. Although tenders from a number of electric light manufacturing companies were called for and received, it is of moment to note that Mr. Preece reported that their terms were all "eminently unsatisfactory." No doubt his criticisms were correct, but as the length of time of the proposed contract was limited to seven years, it is not surprising that they were not such as could be accepted. The lowest and highest offers for each public light arc lamp were £36 and £71 per annum respectively. In spite of amendments in those proposals, Mr. Preece could still find nothing to recommend them; but we, who look back to what has transpired in the interval, can realise that all proposals made in those days, when the security offered was such that capital recoiled from it, were necessarily wild and unsatisfactory, and were mostly made by firms who, if they were sound, must have secretly hoped never to be called on to carry them out. Meantime, the Anglo-American Brush contract for lighting, for about 4,030 hours per annum, New Bridge-street, Ludgate-hill, and St. Paul's-churchyard still ran on, and was costing the City at a rate of less than £25 a lamp. Then, in 1883, commenced a period during which companies proposing to obtain statutory powers within the City were kept at arm's length, and during which Mr. Preece, instructed by the Commissioners, made experiments on the subject of public lighting by arc and incandescent lamps, partly with the aid of the Anglo-American Brush and Edison contract installations then running. In 1883 he reported "that, while the arc lamp is admirably adapted for the illumination of large spaces, the incandescent lamp is eminently adapted for our streets and narrow thoroughfares." Mr. Preece's report to the Commissioners of Sewers, of August, 1884, while being very exhaustive as to the whole question of electricity supply generally, is certainly also the standard report on the subject of public lighting. He then stated, however, that "the lamp which, in my judgment, best lends itself to street-lighting is the glow lamp, and of the glow lamps I prefer the 50-c.p. lamp for the main thoroughfare." Notwithstanding the Holborn experiments, Mr. Preece recommended further trials of public lighting with incandescent lamps, combined with a means of distribution for private lighting within a small area that would require about 5,000 private lamps, at a cost to the city of about £40,000. He also brought very prominently to notice the very valuable proposals of Mr. Trotter connected with his dioptric lantern, to which I shall myself allude later on. These further experiments were never carried out, but I think the meeting will be glad to hear from Mr. Preece if any modifications would now be admitted into his views on a subject which the meeting is aware is not yet satisfactorily settled.

* As international juror for telegraphs and allied electrical applications of that year, my notes on the installation show that the Avenue and Place de l'Opera, and the Place du Théâtre Français, only represented a small fraction of the application of the Jablochkoff lamp then running in France.

† At the same time the Metropolitan Board of Works had been making experiments with the same company's plant on the Victoria-embankment, including photometric comparison of the gas and electric light.

‡ It was estimated to cost over £8,000, but, through the inability of the contractors in No. 2 to commence lighting in time, and for other reasons, it actually cost about £5,400.

Digitized by Google

For more than a year the subject slept.* At that time it fell to my lot to be placed in engineering management of the Anglo-American Brush Electric Light Corporation, and since then, up to July, 1892, I was intimately acquainted with all that has gone on connected with the lighting of the City of London.† The original contract of 1881 of that company for lighting New Bridge-street, Ludgate-hill, and St. Paul's-churchyard with arc lamps still ran; but there were many outward signs of considerable repairs being necessary in the mains. These mains had been laid into the district under the roadways from the Brush Works in Belvedere-road along Bankside, and over Blackfriars Bridge, and they consisted of two circuits of 7/16's drawn into the same cast-iron pipes, with insufficient draw-boxes and means of inspection; although the insulation was sound throughout the greater portion of their length, there were many points at which it had been attacked by the pipes having been hastily laid where they were exposed to soil saturated by sewage liquids and other gases and with insufficient means of access for localisation and removal of faults. The currents were generated by Brush arc dynamos, old-pattern armatures, having belt gearing to engines, which, with the boilers, formed part of the power which was used in the Brush factory, on which the demands were irregular and occasionally very heavy. The fact was that the Brush Company, when they tendered for the work in 1881, understood it was to be an experiment, out of which little or no actual profit could be expected, and little thought that arrangements which would have been good enough for 12 months would be continued by the City authorities for five years, only terminating through the initiative of the Brush Company and by the permission of the Commissioners in December, 1885.

No public body has probably taken more pains than the Commissioners to weigh carefully the *pros* and *cons.* bearing on the question of their becoming themselves the undertakers for supplying electricity‡; and I think now that but for the host of offers, merely speculative and otherwise, which was being continually sent in to them and diverting their attention from the issues most in the interests of the ratepayers, they would in the end have decided on raising the necessary capital to do the work themselves. In November, 1885, a set of proposals was formally made by the Brush Company to contract for the public and private supply of a district of the City, and this was considered by a committee of which Mr. J. C. Bell was chairman. This was the first practical arrangement on a large scale that had ever come before the Commissioners, and its terms are almost *verbatim* those that were eventually adopted in January, 1889, as the conditions under which the Commissioners would receive tenders. From that moment the question of the lighting the City made a fresh start on a tangible basis as to cost and mutual advantages; and although it took five years to mature, there was no longer any serious question of the Commissioners themselves becoming the undertakers. In 1886, 1887, and 1888 the matter was again from time to time before them, and throughout that time it was due to the personal exertions of some enlightened members of the Streets Committee that the matter was kept continually to the front.§ One of the reasons for the delay was due to a great reluctance on the part of the Commissioners to permit any company to have a provisional order within its area of control. The chief reason for this was the condition of things at and below the surface. The occupation of the subsoil by sewers and subways, by the systems of gas, water, and telegraphs, and by various other objects, is entirely exceptional. They would have much preferred that all powers for the disturbance of the surface should be conferred by themselves only, and not by statute. There is no doubt that the ratepayers of the City would now be in quite as good a position if no provisional orders had been granted, and if only the contracts that were eventually entered into between the Commissioners on the one part, and the Brush Company and Messrs. Laing, Wharton, and Down on the other, were existent. Owing to more than the ordinary rights of user of the soil of thoroughfares and streets being vested in the City Corporation, statutory powers were not necessary to enable them to grant way-leave.‖ In February, 1888, the Commissioners called for a report giving a *résumé* of all that had been brought before them in the previous 10 years; and I must here say that it fully establishes the claim of the Brush Company that a large share of the credit for the eventual results was due to their persistence in holding the ground when all others had retired, and in keeping the subject always before the local authority in a manner and in terms which by their moderation and practical sense were bound in the long run to commend themselves to business people. The object of this report was to show that the successful use of arc lamps for illuminating large spaces had asserted itself all over the civilised world.* The advantage of having a contract with a company to supply current to public arc lamps at 3·1d. per unit, including trimming and carbons, instead of at 8d. exclusive of the same—the usual price in provisional orders—was dwelt on. The unsatisfactory nature of the proposals made to the City by other parties was fully exposed. The great advantage to the City of the terms of the form of contract originally proposed by the Brush Company in 1885 were adopted, and the misrepresentations which suggested monopoly that had been made were dispelled; and it is a remarkable fact that the then proposed charge of 1s. per unit for private lighting was not considered excessive in view of the circumstances of the probable demand for business premises in the City. January, 1889, found the Commissioners, again, and finally, roused to activity by the Electric Lighting Act of 1888 (due to the personal exertion of Lord Thurlow, the chairman of the Brush Company), and, the City being divided into three districts for the purpose of the contracts, tenders were publicly called for; and it may here be remarked that the company which during eight years had done so much to keep the matter before the public, at that moment was in no better position in March, 1889, as regards tendering, than any other firm which was then only dealing with the matter for the first time.†

But yet another stage of opposition had to be got over before the final arrangements for this great undertaking could be said to be on a satisfactory footing. Major Marindin, in April, 1889, had reported against the claim of the City to be exempted from the operation of the Electric Lighting Act, and had, in face of the opposition of the City, recommended the approval by the Board of Trade of the applications for provisional orders from two of the above-named companies. The Brush Company had for several years, in deference to the views held by the City authorities, refrained from making applications for orders, and therefore their absence from the list of applicants in 1889 was intelligible. In the terms of Mr. Preece's report on Major Mandarin's contention, the City had been "regarded merely as a local vestry with some ancient rights that have to be respected;" and that "the amount of lighting and the capital necessary to be expended in the City, which far exceeds that for any other portion of the Metropolis," had been overlooked. Major Marindin by his recommendation had neglected not only the geographical part of the question, but the fact that the Commissioners of Sewers had been for years studying and experimenting on the question of effective public street-lighting. The tenders for public lighting the main thoroughfares with arc lamps which eventually were reported on, in November, 1889, by Mr. Preece and Colonel Haywood, were the Metropolitan Electric Supply Company's revised tender to light the western district with 121 lamps, at £26, £3,146; the Anglo-American Brush, the central district with 138 lamps, at £26, £3,588; the London Electric Supply Corporation, with 136 lamps (half the lamps being extinguished at midnight), at £24. 2s., £3,290—total for the main thoroughfares, £10,024; and the acceptance of these was recommended. But of them the Brush Company alone (consistent with their original proposal) had not applied in 1889 for a provisional order, and had agreed to the division of profits under a sliding-scale—namely, that if the profits exceeded a cumulative dividend of 10 per cent. per annum upon the capital invested, the excess was to be divided equally between the contractor and the consumer—and also had agreed that power should be reserved to the Commissioners to acquire the undertaking and works by purchase at the end of 21 years, in all other respects in accordance with Section 2 of the Electric Lighting Act of 1888

Meantime, no provisional orders had been granted for any part of the City area, owing to the withholding of the usual recommendations from the local authority which the Act requires. But on the last day of June of that year the Brush and the Laing, Wharton, and Down Companies gave notices for the western and central and the eastern districts, respectively, and the ordinary statutory steps followed in due course. The Brush Company had, as stated, accepted the terms of the Commissioners' contract, and the Laing, Wharton, and Down Company now decided to fall into line with them;‡ and in May, 1890, those contracts were sealed, and the provisional orders became law in that session of Parliament.§ Not until 1891 were a similar contract and provisional order granted to the Brush Company for the western district. Thus, after nearly 13 years of deliberation on the subject, the scheme for supplying electricity to the City of London for public and private consumption became legally possible, and all the special powers which the Commissioners sought to obtain in the interests of their ratepayers had been secured.

(To be continued.)

* In November, 1885, a well-known writer reported to the Commissioners: "At the present time there is a complete stagnation in electrical enterprise in England, in such enterprise as would undertake the supply of electricity upon a large scale for public and private purposes in towns."

† My own connection with the public lighting of the City of London dates back to the sixties, when I assisted the late Dr. Letheby, city analyst, in a series of experiments connected with carburetting gas for street lamps.

‡ So late as April, 1890, they deputed Mr. Preece to report to them on the electric lighting of the public streets of Taunton with arc and incandescent lamps.

§ Mr. Frank Green, Mr. J. C. Bell, Mr. Graham King, Mr. Bridgeman, Mr. Pannell, and others.

‖ There is ample experience to show that if much of the Act of 1882 had been repealed, so far as the Metropolis was concerned, as was more than once urged on the Board of Trade, this and many geographical and other anomalies which have kept up, and will for many years keep up, the price of electricity in London, might have been avoided.

* The successful lighting on a large scale by the Brush Company of the Colonial, Manchester, and Glasgow Exhibitions was described.

† The contractors who tendered were the (1) central, Anglo-American Brush Corporation; (2) London, London Electric Supply Corporation; (3) west, Metropolitan Electric Supply Company; (4) all, House-to-House Electric Supply Company; (5) east, Messrs. Laing, Wharton, and Down.

‡ The Commissioners had required Mr. Preece to report fully on the Thomson-Houston system of arc lighting as established at Sheffield and the St. Pancras Station, as well as at Taunton.

§ The names of Mr. E. Garcke and of Mr. Sydney Morse are so well known in connection with the industry, that it is appropriate to record here that to them is largely due the credit for carrying through final arrangements for these orders, which were exceptionally intricate in their character.

TENDERS AND TENDERING.

The peculiar condition of affairs at Newport, coming on the top of a warm discussion relating to matters at Coventry, will perhaps do more to open the eyes of local authorities to certain consulting engineers' practices than any amount of cogent criticism without such revelations. Let us examine for a moment the general object to be gained in obtaining tenders; but, first, a few words relating to consulting engineers, taking it that such persons are employed. The consulting engineer is *supposed to be* unconnected with any of the tendering firms; he is supposed to be an expert who, for a certain remuneration, will give his whole and undivided services to the preparing of plans and to the proper advising of his employers. If he is inexpert, or if he is in any way connected with tendering firms, or if he induces his employers to believe in him by appeal to seemingly unbiassed authorities when at the same time those authorities—journalistic or otherwise—are in his pay and under his control, then something altogether foreign to old-fashioned consulting practice must be looked for. Perhaps, however, we must look upon the consulting engineers of the *fin-de-siècle* order as commencing a new departure which older fogies do not at present countenance, but which may in the long run prevail over the old order of things. The consulting engineer, then, supposed to be an expert and to know his business from beginning to end, prepares his plans and specifications—for what? Usually we take the desire to be to get those plans carried out according to those specifications at the smallest cost to his employers. If the plans are carried out according to the specifications—and it is the engineer's duty to see that this is done without fear or favour—we must emphatically and deliberately maintain that he is not justified in recommending any except the lowest tender. Thus, we contend, the consulting engineer at Newport is going altogether outside his duties, and is not acting fairly to his employers, in recommending contractors whose tenders will cost more than the lowest tender. The—shall we term it—waiver clause in most advertisements, to the effect that the authority does not bind itself to accept the lowest or any tender—is a clause usually inserted, and properly so, for quite another purpose than whitewashing wrong actions of any authority. There are often tenders sent in manifestly of no *bonâ fide* character, and from firms who have another object than that of getting the contract in view, and it may be that obviously fatal errors have been committed in the figures of which no well-meaning authority could take advantage. Putting aside those tenders sent in *malâ fides*, and those obviously incorrect, there is absolutely no moral, legal, or commercial argument for accepting any but the lowest tender. If such other should be accepted or recommended the procedure savours of favouritism, a thing which is not recognised in commercial practice when tenders are concerned. The consulting engineer has also his privileges and his duties towards contracting firms, and if he is thought to persistently favour one or some above others, the

Digitized by Google

inevitable result arises that firms of repute, firms of the highest standing will have nothing to do with him or his works; hence he cannot give what his employers want. The course of proceedings at Newport is, to say the least, unsatisfactory. There is, so far as we are aware, no suggestion that the consulting engineer prefers incompetent to competent contractors; the only question in dispute is the choice between two competent firms, one of which tenders lower than the other. The only reason so far assigned for the selection of the higher tender is that the firm sending in the lower tender has had less experience in a certain direction than the other, and is by some people looked upon as a firm wedded to an opposite system. To our minds, such an argument, if true, is not worth the value of a farthing rushlight; but in this case it is not true. The firm referred to is the oldest—or almost the oldest—in the trade, has had far more experience than the firm selected, and has always denied being tied to any one system, arguing that in every case the system to be used must be adopted to the circumstances under which it has been used. In this article we have dealt more with the abstract question of tenders rather than with the concrete example, using the latter only as a peg to hang a sermon upon. The other questions that might and perhaps will have to be considered are the competency or incompetency of the engineer as shown by his works, and the methods, journalistic and otherwise, used to obtain the confidence of local authorities. History does not often err in its lessons, but history may be misrepresented and conclusions drawn therefrom which are incorrect. We shall await the further development of the Newport matter with some interest, and trust that at the eleventh hour the *fin-de-siècle* methods may give place to the old sturdy views—to do what is right, and care for nobody.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

NAME OF FIRM.

SIR,—Owing to the numerous enquiries we have had recently as to whether we have changed the constitution and address of our firm, we feel it incumbent on us to state that there has been no change whatever, and that the partners, F. H. Nalder, H. Nalder, C. W. S. Crawley, and A. Soames, who have conducted the business during the last six years, still carry it on as Nalder Bros. and Co., and that our sole place of business is at 16, Red Lion-street, Clerkenwell, London, E.C., as heretofore.—Yours, etc.,

NALDER BROS. AND CO.

AIR-CORE TRANSFORMERS.

Messrs. Frederick Bedell and Albert C. Crehore write as follows: In a paper on "The Behaviour of an Air-Core Transformer when the Frequency is Below a Certain Critical Value," read before the Physical Society, October 27, 1893, Mr. E. C. Rimington has called attention to the case in which the primary current of a transformer falls off when the secondary is closed. This phenomenon was noted by us last spring, and attention called to it in the *Electrical World*, June 17, 1893, in Article V., on the "Theory of the Transformer," where a curve is drawn, Fig. 14, showing the value of the primary current for different loads. We have not yet seen the full text of Mr. Rimington's paper, but from various references to it would infer that much of the same ground has been covered by him as was given by us in a paper before the Electrical Congress in Chicago last August, entitled "General Discussion of the Current-Flow in Two Mutually-Related Circuits Contained Capacity," printed in full in the *Physical Review* for September-October, 1893. In a more recent communication, Mr. Rimington calls attention to the fact that Mr. Kennelly, in an article entitled "The Impedance of Mutually Inductive Circuits," in the *Electrical World* for October 21, covered some of the same ground as given by him in his paper before the Physical Society above referred to. In a geometrical treatment of the same subject, "Theory of the Transformer—VIII.," *Electrical World*, November 25, we showed the identity between analytical and graphic methods of solution, including that of Mr. Kennelly, and showed that the whole is derivable from the results given in the paper above referred to, presented by us before the Electrical Congress.

This decrease in the primary current of the transformer as the load increases, where the constants of the transformer have certain particular values, is certainly an interesting one, although the amount of increase would always be small. Although the transformer has been the subject of a great deal of discussion, and its theory has been approached from all sides, and the instrument experimented upon by many different methods, it is still a fruitful source of study to the theorist and experimenter, and there is still room for the discovery of many facts interesting and unique.

January 30, 1894.

THE UNDERGROUND ELECTRIC LIGHT MAINS IN THE CITY OF GLASGOW.*

BY WILLIAM LACKIE.

Although this paper is put down as one on "Underground Electric Light Mains," I do not intend going into the subject generally, but rather to give a short description of the electric light mains laid down in Glasgow, and the work connected with them.

In the beginning of August, 1892, the Corporation here engaged a contractor to lay down mains, to supply electricity to private consumers on what is known as a low-pressure three-wire system. The three-wire system consists of two dynamos, or sources of electric current, connected together in series, and three wires taken from them, one from each outer terminal, and one from the connecting point. The current generated in No. 1 dynamo and raised to a potential, or pressure, of 100 volts, might be said to pass into No. 2 dynamo, where it is raised another 100 volts, so that between the two outer terminals we have a difference of potential of 200 volts, and between either of the outer two and the middle wire 100 volts.

At present there are lights equivalent to 20,000 8-c.p lamps between the positive and middle, and an approximately equal number between the middle and negative. All the current that goes out from or comes back to the station along the middle wire is what is necessary to light the difference in number of lamps lit between the positive and middle, and the middle and negative. This is generally very small, and never should be over 200 amperes.

The generating station has been erected at the south-east corner of Waterloo-street and Mains-street, and mains are laid eastwards along Waterloo-street to the city, and up Mains-street to Sauchiehall-street. The arrangement of the dynamos here is a slight modification of the simple three-wire system. There are nine dynamos in all, but only two of these, and two sets of storage batteries of 57 cells, are joined in series, and the middle wire is taken from the connecting point between them. The remaining seven dynamos give out their current direct at 200 volts, and have no middle-wire connection. The two dynamos which are joined in series are called the "balancing machines," and

* Paper read before the Physical Society of Glasgow University.

Digitized by Google

they, along with the batteries, supply whatever current is required along the middle wire.

You will see that with this arrangement there is only half the number of machines to look after; also, there is a saving in mains, as you have two mains in place of three, which would be required if all the machines were 100-volt machines joined in series for the main supply. The mains off which consumers get their supply consist of three wires — positive, middle or neutral, and negative. Lamps connected between the positive and middle are said to be on the positive side; and lamps connected between the middle and negative, on the negative side of the system.

Originally it was thought that all the mains might be laid down on a system of bare copper strip, supported on insulators, placed in cast-iron troughs, bolted together and laid under the pavement. However, on examining the principal streets, it was found that there were so many cellars below the pavement, with the arch of the cellar close up to the flagstones, there was no room for the troughing, so a combined system of bare strip and insulated cables in pipes has been laid down. The sole reason that troughs and bare strip were not laid in all the streets was that in some streets cellars ran the whole length of the street, and in others cellars only here and there, which meant far too many manholes; for, where troughing stops and pipes begin, a manhole has to be built to allow the jointing of the copper strip to the insulated cable. These troughs consist of cast-iron boxes of the shape shown in the drawing. They are cast in two sizes, called "three-way" and "five-way." They are both 4ft. 6in. long and 7in. deep, but the three-way is 18in. broad and the five-way 21in. broad. To lay the troughs the pavement is removed for a distance of about 40 yards, which is the length that a squad of about 15 men can do comfortably in a day. A trench is then dug, 18in. deep, and rather broader than the outside size of the troughing to be laid, as the troughs have to be bolted together from the outside. The troughs are then laid into the trench on fairly and truly bedded ground, and levelled transversely, but they have always a sufficient slope to drain into a manhole which is placed at the end of the length. The streets of Glasgow lend themselves very well to this, as most of them have a natural slope. The troughs fit one into the other, and are jointed with red-lead putty, and securely bolted together with two bolts, one on each side. The whole length of troughing is laid first, and then cleanly swept, and the insulators and tiles put in in their proper places—*i.e.*, one insulator at the beginning of each trough, and two tiles equally spaced between them. Snugs are cast in the trough to hold the insulators and tiles in their proper position. The insulator supports the copper strip, and the tiles will, should the copper strip sag, prevent it touching the bottom of the trough. Both insulator and tile are arched on the bottom so as to allow a free flow of water, should any find its way into the trough.

The requisite number of copper strips is now pulled in and placed in the grooves of the insulators. All the copper strip laid is of the same size—namely, 1in. broad by ¼in. thick. If a larger main than this is required, two or more such strips are pulled in and laid flat one on top of the other. When the requisite number of copper strips has been laid in they are gripped together at one end in an iron grip-box (shown), and at the other end a lever is applied to each strip, one at a time, and stretched until each strip is perfectly straight. Not only does this stretching straighten the copper, but as the first trough is used as a stay at one end, and the last as a heel for the lever at the other, it has the effect of pressing all the troughs firmly together, and allowing them to be more tightly bolted together. Red-lead putty is now laid in a groove along the edge of the troughing and the covers laid on carefully. The ground can now be filled in and the pavement replaced.

At the end of each length of this troughing a space of about 2ft. is left, before starting another length, for a manhole to be built. A manhole consists of four brick walls built in a square of about 2ft. or more. The bottom of the manhole is always 15in. clear below the lowest way, troughing or pipes leading into it. It has a square iron frame laid on top of the brickwork, with a U-shaped projection on its inner edge for carrying the manhole cover, which consists of an iron framework or box filled in with concrete. This frame or box has two rectangular notches in two opposite sides for the purpose of lifting it, with two suitable handles when desired. The cover fits into the frame, and is jointed with red-lead putty and yarn.

The troughing has never been laid below the roadway, as it would not have been safe, owing to the great weight it might be called upon to carry, and also in case of subsidence, such as we have had too often of late, which might cause serious damage and inconvenience. Across the roadways, cast-iron pipes are laid, varying in size from 2in. to 6in., so that at the corner of most streets you will see a manhole, where the troughing stops and pipes begin. Insulated cables are pulled into those pipes, and tinned copper thimbles soldered on to the ends, and then the copper strip and cable are clamped together in a gunmetal grip-box. Should the copper strip expand, the insulated cables are flexible enough to give a little in the manhole. In long lengths of copper strip we have tried expansion joints in an intermediate manhole, but I do not know if they are ever called upon to work. This system of gripping the copper strip and cable together is perfectly good for the theoretical resistance of a main, and the measured agree to within 2 per cent.

This whole system of underground mains is simple, and, as far as I have seen, very good. A piece of ground can be opened in the morning, and the mains laid and closed again by night. Had concrete culverts been used, they would, in Glasgow, have been more expensive, and the ground would have required to be open for three or four days. I know that the patience of the merchants and general public was severely taxed even with the one day's turn-up. I have heard it said that those troughs were not absolutely watertight. They are not, but are not very far from it. However, I see no very serious danger arising from this. The pavement over them is always laid firm and on a slope towards the gutter, and keeps the ground below almost perfectly dry. A great many of our troughs are laid below granolithic and asphalte, and are therefore watertight so far as rain and snow are concerned. Should water find its way into the troughs, it will immediately flow down to the nearest manhole, where it drains away naturally; or if it does not, a drain is laid from it to the nearest sewer. So long as the lowest manhole in a district is well drained, I think there is little chance of our mains being flooded, for should it rise in one manhole, it will immediately flow either by way of the pipes alongside the troughing (to which I will refer immediately), or along the troughing itself until it reaches the lowest manhole. Alongside most of the troughing two pipes are laid—one for carrying the cables for the street arc lighting, which is on a different system to that of the private supply, and the other for carrying potential or test wires, which run back from various parts of the city to the station for the purpose of testing the potential at those points.

The supply mains, or network of the city, therefore practically consist of three copper mains each ¼ square inch area, either in the form of bare strip or insulated cable, and are painted in the manholes—the positive, blue; middle, white; and the negative, red. Not long ago, it was the habit to paint the positive red and the negative blue, but I believe that since Wilkes's pole-finding paper (which turns red at the negative pole on passing a current over it) has come into use so much, the colouring of the positive and negative has been reversed. Had strip been laid everywhere, there would have been no necessity to colour them, as a rule—that the positive must be laid next the building, or always to the north or west side of the troughing—could have been adopted.

The middle wire leaving the station is connected on to the network or supply mains at the point nearest to the station, but the positive and negative wires are not. There are a number of positive wires and an equal number of negatives, called "feeders," which leave the station and carry the current out into the city, and are joined on to the network at nine different points, called "feeding points."

Digitized by Google

It is from those feeding points that the potential or test wires are carried back to the station, and the pressure of the current is varied in the station so as to keep the difference of potential between the middle and positive or negative a hundred volts. You will see that, since the feeders have to carry the total current sent out from the station, they must be of a greater area than the network. The area of the feeders varies, according to their length and the district they are likely to supply, from ½ square inch to 1 square inch.

In a water supply there is always a certain amount of pressure lost between the pumping station and the point at which it is delivered; so in this electricity supply, although the current is sent out at a pressure of 230 volts, we may only have 200 volts at those feeding points when there is a current of 6,000 or 7,000 amperes going out. If a small current of 400 or 500 amperes is going out, the fall may only be two volts. The fall of potential along a wire varies directly as its length and current flowing along it. The feeders, therefore, should be of such a length and area that the fall along each is the same, in order that they may take their supply from the omnibus bar of the switch-board, which is, as the word indicates, the bar to which all the dynamos are connected.

At the beginning of any station it would be very difficult to make them of the proper area. The length is practically fixed by the district or streets to be supplied, but no one knows what the current along each feeder is to be. Once the station has been running for some time you can easily, by pulling in either larger or more cables across the roadway, or by pulling in an extra copper strip, make your feeders such that the fall along each is the same to their respective feeding points. If a specially heavy load comes on in any one district, and the feeder to it is called upon to carry more than its usual load, it is a very simple matter for the night or two to connect a dynamo giving its current at a higher voltage on to that feeder.

The feeders, when laid in cast-iron troughs, consist of three or four of the ¼ square inch copper strips placed one on the top of the other. When iron troughs are not used the feeders take the form either of an insulated cable pulled into a pipe, or of a steel-armoured cable made by Siemens and Silvertown. This armoured cable consists of an insulated cable covered with lead, coated over with yarn or hemp, and then served with two coatings of steel ribbon, and the whole yarned over. Those armoured cables are simply buried in the ground, with a tarred board over them, to indicate where they lie should digging operations be going on near them.

I would just like to say one word on potential leads. They give more bother to keep in order than all the other mains put together. You will remember a slight explosion which occurred in Bath-street in November. The gas in the manhole was undoubtedly fired by a potential lead, which had never shown any signs of its insulation breaking down before. The gas in the manhole had not been accumulating there for weeks, but had gathered in a few days. A very badly damaged gas-pipe was found quite close to the manhole. We have had to renew our potential leads two and three times in several parts of the city, while in other parts they have given us no trouble. I have been told that in London stations a potential lead burning out is a common thing every five or six weeks. The potential leads or test wires we have tried consist of an insulated cable of copper wire containing seven strands of No. 20 gauge. Three such cables make up the lead going to one feeding point. These wires have been pulled into a 3in. cast-iron pipe in bunches of 12, and some have given no bother at all, while others have two and three times been found smouldering away in the pipe. The insulation of the cables is not damaged in the pulling in, as their insulation resistance has been taken from time to time and found to be quite good.

While speaking of insulation, I will just refer to the insulation we get on large insulated cables pulled into the street crossings. Although Silvertown and Henley cables have been used with a guaranteed insulation of 600 megohms to the mile—so that in a length of 20 or 25 yards the insulation one would expect is something like 45,000 megohms—instead of this, the insulation is more like 45,000 ohms, which, I think, is purely due to surface leakage along the covering of the cables to the pipe into which they are pulled. Again, we have here 600-megohm cables connected direct on to bare strip in which the insulation is not more than 300,000 ohms per mile. I consider that a high insulation is not of so great importance on underground mains, so long as you have a steady insulation resistance to earth of, say, 500 or 600 ohms. The leakage through this will amount to very little in the year compared to what is lost through shunt circuits in meters, voltmeters, etc.

I should think that some cheaper material not having such a high insulation resistance as rubber, but at the same time durable, must be used. Paper insulation has been used, but I do not know with what success. Here troughing might be employed, made strong enough to stand the weight of the traffic, but it would necessitate the manholes being very deep and large. Copper strip or rod might have circular porcelain insulators fixed on to them, and pulled into an iron pipe in place of the insulated cable.

A great deal has been said against and in favour of this bare copper strip and culverts. The bare strip and iron culverts have now been in Glasgow for fully a year and a half, and the current has been on the mains continuously for a year, and we have never had any more serious trouble with them than we have had with insulated cables in pipes. I think the copper strip is all right, but I do not care so much for the iron culverts. I would like to see the copper strip with a slight covering of some insulating material. There is no necessity for having finely-tinned copper flexible cables made to be below streets. Flexibility is not so very necessary in underground mains. We have not yet had long enough experience with the iron culverts to know the effect of years on them. Scale will probably form and drop off them and make short-circuits, but I am afraid the culverts will get very dirty in course of time and require cleaning out. I would like to see concrete or earthenware culverts made on the same principle as the iron ones.

Mr. Crompton says, in a letter of the 8th November: "It is very easy to prove that the 30 miles of mains laid in London consisting of bare strip are in as good order as when first laid, and that during the time they have been down—in some cases over seven years—they have cost less for testing, inspection, and maintenance than any other system that has been tried."

We have been troubled very little by gas in our manholes, and whenever we have smelled any, the Gas Department has immediately remedied it.

When anyone wishes a supply of electricity for lighting or motive purposes, he must fill up a form stating the amount of energy wanted. A branch of a suitable size of cable is then taken off the network—*never* off a feeder. If the branch is to be taken off at a part where the network consists of insulated cables in cast-iron pipes, a part of the pipe, about 18in., is cut out altogether. The two proper cables (either the positive and middle or middle and negative) are then bared, and the branch wires soldered on. The bare part is then covered over with rubber, and made as good as the original cable. A joint-box which has two small holes in its side is then bolted over the pipe and jointed with putty. Malleable iron pipes are laid from this joint-box into the consumer's premises, and the branch cables pulled into those.

The Corporation terminate their mains just inside the building line, in a main fuse-box supplied by them. A contractor does all the work inside the premises, and brings the mains to this fuse-box, leaving a bight at some suitable place for a meter, which the Corporation supply. If the connection is to be taken off the bare copper strip, the operation is simpler and easier. The pavement in front of the premises is lifted for about 5ft., and one cover (4ft. 6in.) is taken off the iron culvert. The copper strips are then tinned or filed clean, and the branch cable, which has previously had a skew thimble soldered to it, is clamped tight to the copper strip with a split grip-box. A short cover (3ft. 6in.) is then placed over one end of the culvert, where the branch has not been taken off, and a special cover, 1ft. long, having two holes in the side, is placed over the branch. Malleable-iron pipes are led from this cover into the consumer's premises as before, and the branch

Digitized by Google

cables pulled into them. This method of taking off a branch is much simpler. It can be done in a third of the time an insulated joint takes, and is easier undone if it is found necessary to do so.

As I mentioned before, the current for the public arc lighting of the street is not supplied from the private supply mains, but is supplied from a station situated in John-street. The lamps are lit by means of a continuous high-pressure current. The mains for carrying this current consist of insulated cable of seven strands of No. 16 wire, and is carried in a cast-iron pipe laid alongside the troughing. A current of about 10 amperes at 3,000 volts is sent out from the station, and flows through 50 arc lamps connected in series. In the base of each lamp a switch is placed, by which the current may be turned completely off the lamp and allowed to pass on to the other lamps. This allows the lamp-trimmer to trim the lamp without any chance of receiving a shock, even although the current is on the mains.

For fully six months the Corporation have themselves continued the laying down of more mains, and I am quite sure that those mains have been put down better and more cheaply than they were done by the contractor. It was most unsatisfactory for the contractor to be hindered by gas branches in his way. The Corporation men can easily change the gas branch and continue laying the troughing without delay. In no manhole have we been bothered with gas where the gasmen have laid the troughing, for the simple reason that they have overhauled, and in a great many cases relaid, the gas-pipes all along the course of the electric light mains and round about the manholes.

I may state, in conclusion, that I am strongly in favour of corporations undertaking this sort of work themselves, more especially if the gas and electric light departments work as harmoniously together as they have done in Glasgow.

It would not be right that a paper on the underground electric light mains in Glasgow should close without referring to an article which appeared in one of the electrical contemporaries a fortnight ago. It begins by stating the date on which the recent explosions took place. It is interesting to note that an equal number of explosions took place while the mains were being laid and, of course, before any current was on the mains. The gas which had accumulated in the Bath-street explosion was fired by a short-circuit on a potential lead, as I said before; the one in West George-street by a naked light used by one of the workmen.

The third has not been explained, but a passer by states that he saw a flame playing about the manhole cover before the manhole cover blew up. This would seem to show that the gas which caused the explosion was fired from the outside, not from the *cables* in the manhole; no short-circuit or potential lead caused it.

How the gas got into the manhole was not, the writer of the article thinks, by infiltration; but he goes on to say that the culverts subside, and the weight of the troughs breaks the gas service main, allowing gas to blow in through the joint opened up by the subsidence. This is a very poor explanation, I think. Why should the ground begin to subside now? As a matter of fact, the ground below the troughs has hardly been disturbed at all. Again, most of the gas branches cross over the top of the troughing; the branches are of malleable iron, and are set in a V-shaped piece of wood, with fully an inch of pitch laid on the top of pipe. Again, had the troughs subsided, the copper strip would undoubtedly have touched the lid of the troughs and have made a short-circuit. This, however, has never happened.

The writer of the article says, with great confidence, "that buckling of the strip within the Glasgow culverts has taken place is certain," but where he got this information I cannot tell. In the same paragraph he says, "expansion joints are *now* being introduced at the junction-boxes, and this certainly is an important step." Those expansion joints were put on in March and April of last year, and I do not think an extra one has been put on since. Continuing, in the same paragraph, he says, "another great defect in the Glasgow culverts is that the several 4ft. 6in. lengths are not properly connected together electrically." Now, they are; there are 2⅝in. iron bolts holding the troughs together, and those are screwed up so tightly that I have seen a length of 20 yards of five-way undermined and no signs of the troughs subsiding.

The article concludes by referring to the foolishness of the Glasgow authorities pulling potential leads through cast-iron pipes, which are rough inside. He is again quite wrong here, as the pipes in which the potential leads have given way have been examined, and a hard ball pulled through to see that no rug or roughness was in the pipe, and none was found. If this was the cause of the wires giving way, the wires which had been pulled furthest would be the most damaged; but this is not the case.

On the whole, the article is untrue; and I think the electrical journal in question ought not to make such damaging statements about the mains in "the second city of the empire—the city of engineers" without first enquiring into the truth of them.

With regard to the ventilation of the manholes and troughs, there is now nearly 500 of those manholes in the city, and only some half-dozen have any trace of gas in them, and this is undoubtedly traced to gas-pipes damaged either by the operations of the underground railway or of the new sewer now being built in the city.

At the same time, we are continually on the look out for more gas escapes and reporting them to the Gas Department, who pay prompt attention to them. By this means we hope to prevent any further serious explosions.

THE THEORY AND DESIGN OF THE CLOSED-COIL CONSTANT-CURRENT DYNAMO.*

BY HENRY S. CARHART.

(Continued from page 141.)

Suppression of Sparking.

If we assume that the armature is well balanced electrically and magnetically, and that the brushes have a proper bearing in contact with a smooth commutator, the conditions required to commute the current without sparking are known to be as follows: With a two-pole dynamo, the current is divided through the armature—one half going from brush to brush through one side, and the other half through the other side. Hence when an armature coil is carried past the brush it is transferred from the one circuit through the armature to the other, and at the same time the current through it reverses its direction. This constitutes the act of commutation. But the sudden decay of a current through a coil in one direction and its growth to an equal value in the other gives rise to an E.M.F. of self-induction opposing the change. This E.M.F. will prolong the flow of the current on one side of the brush and will oppose its rise on the other side. Hence if the coil is short-circuited by the brush lapping over the two consecutive commutator segments to which its ends are connected, even when the coil passes the neutral plane of the dynamo, the E.M.F. of self-induction produces a local current through this coil; and when the one end of the coil slips past the brush and becomes a part of the other half of the divided circuit the current which should reverse through it meets the opposing current and breaks over the gap to the brush with a spark. Hence the commutation must not take place at the neutral plane, but in advance of it, and in a field where the induced E.M.F. in the coil shall be just sufficient to offset the self-induction, and in addition reverse the current in the coil while it is passing the brush or pair of brushes, and cause it to grow to the normal value at the instant when one end of it passes out from under the brush. The induction from the field must be sufficient to bring the one current to zero, and to set an opposite one of equal value flowing in the coil during the time it is under the brush. Then the commutation will be sparkless.

Now, if the current is kept constant in strength the field induction required to accomplish the results described is approximately the same whether the coil is short-circuited at one angle or another in advance of the neutral plane. It

* Paper read before the Franklin Institute, December 26, 1893.

Digitized by Google

would appear at first thought that unless the induction in every part of the field from the neutral plane to a point nearly 90deg. in advance of it is substantially uniform, terrific sparking must result when the brushes are shifted far forward to vary the electric pressure to suit the requirements of the circuit, for if the induction is in excess of the requirements to accomplish the result described in the commuted coil, then a current will circulate through it during the short-circuit, and the rupture of this on leaving the brush will cause sparking. I have illustrated this action in the following manner. Separately excite the field magnets of a machine which can run on short-circuit even with a forward displacement of the brushes without sparking. Then, leaving the armature on open circuit, rock the brushes forward; the sparking will increase with each advance till it becomes terrific and endangers the machine. The induction to which each coil is subjected in an excited field produces a large current in it while it is under the brush, since there is less self-induction in the coil to offset the induction from the field than there is when the machine is self-excited and working in the normal way. There is another reason to be described later.

Considerations of this kind have led some writers to say that sparkless commutation for any position of the brushes can be accomplished only when the induction in the field is made uniform. The Statter constant-current machine in England is made on this principle. Portions of the pole-pieces are laboriously cut away at such points as to make the density of the lines of force entering the armature over a given angle equal. Of course, a machine built in this way will permit of shifting the brushes through a considerable angle in order to vary the potential difference without introducing sparking.

But while a uniform field accomplishes the result, no such uniformity is required; the same result may be secured in other ways. The first method already described weakens the field when the brushes move forward by cutting out ampere-turns in the field magnet. This reduces induction to the proper amount at each point without changing the overlap of the brushes. It is made necessary by the very high saturation of the armature core in this machine. It has the advantage of greater economy with small loads, because field resistance is cut out, but it requires a more complex arrangement of parts on the machine than suffices for the mere movement of the brushes.

The second method diminishes the overlap of the brushes as they are rocked forward. In the first place, this has the effect of diminishing the time allowed for the reversal of the current, but it also diminishes the number of turns of wire in the coil or coils included between the two parts of each brush. The curtailed time interval increases the self-induction of each convolution of wire because it increases the rate of charge of the current in the coil undergoing commutation; but this increase is counterbalanced by the diminution in the number of turns of wire short-circuited by the brush. Hence, the total self-induction during commutation remains not far from constant. When the brushes shift forward into a denser field, however, the diminution in the overlap decreases the number of turns of wire included between the pair of brushes composing either the positive or the negative, and so cuts down the total field induction in these coils during commutation to the amount required to suppress sparking. The overlap of the brushes must therefore be inversely as the induction in a coil under the brush is to different parts of the field, for the presence of the pole of the armature at any point reduces the induction. This point is a complicated one, and needs further experimental study.

But in the third class of machines the overlap of the brush is constant, and the field is not weakened by cutting out coils on small load. Neither are the pole faces cut away to produce uniform induction. Attention is given to the thickness of the pole-pieces so as to avoid unnecessary crowding of the lines of force toward the central portions. It is also desirable to avoid thinning of the polar horns lest they become saturated. In the old Sperry machine, which I have investigated quite carefully, each pole-piece is cut quite in two. In fact, as is well known, the field has four cores. At the same time the horns or pole tips are rather blunt. But this machine shows the violent sparking when separately excited, with the brushes far forward and the circuit through the armature open. The induction around the armature is not uniform, but the sparking is small for any position of the brushes with the normal current. The brush bears on about three commutator segments. I refer to this machine as an illustration of the class and not as a model of excellence. It is no longer built.

In this machine the induction to which a coil is subjected near the brush is not the same in different parts of the field, but diminishes as the brushes are rocked forward, the current being kept constant. With the exploring coil before described, and the two extra brushes bearing on the insulated copper ring and the fibre collar with brass segment respectively, the external circuit connecting the two small brushes was carried through a d'Arsonval galvanometer in shunt. The two extra brushes were attached to the two main brush-holders, but were insulated therefrom. With one brush making contact with the small brass segment, two and then three commutator bars in advance of the upper main brush, the following deflections were obtained with the galvanometer from maximum to minimum.

Deflections, two segments.	Deflections, three segments.
26	63·5
24	56

20	41
18	34
16·5	32
13·5	—
12·5	28
10·5	—

The steps were not the same in the two series of observations. No trouble was found in obtaining a steady deflection of the galvanometer, the dynamo making about 1,200 revolutions per minute. The exploring coil was therefore subject to a diminishing induction near the brush as it moved forward with the brush toward the centre of the polar surface.

A similar series of experiments made on an old Gramme machine of 3,000 or 4,000 watts capacity, built at the University of Michigan in 1876-7, gave a different result. The measurements were made by simply connecting a third brush to the upper brush-holder and measuring the potential difference between it and the main brush in different parts of the field. The actual induction to which the armature wire is subjected in different parts of the field and at the same distance of two commutator bars from the main brush is thus measured.

The following table contains one series of observations:

No. of observation.	Current in amperes.	P.D. between main brushes.	P.D. between main and third brush.
1	9·5	191	4·9
2	9·5	170	5·4
3	9·5	145	5·5
4	9·5	127	6·2
5	9·5	111	6·5
6	9·5	77	7·7
7	9·5	62	7·8
8	9·5	54	7·7
9	9·5	47	7·4

In this case the induction increases throughout the larger extent of the movement of the brush. But in this machine the knee of the characteristic curve is reached at about 13 amperes, while in the other machine it is found at seven amperes. The armature reaction in this older machine when run at 10 amperes is relatively less than in the other one run with the same current. This is further evident from the fact that with the old Gramme run at 10 amperes an increase in the current, due to lessening the external resistance, is always accompanied by an increase in the potential difference between the main and the third brush, while with the 10-light Sperry machine and others with similarly saturated field an increase in the current when the brushes are fixed decreases the potential difference between the main and extra third brush. The reason is this: If the field is saturated, but not the armature, an increase in the current does not appreciably increase the field, but it does increase the armature reaction, and so cuts down the total potential difference between the main

Digitized by Google

brushes as well as between one main and a third brush; while with an unsaturated field and a magnetically weaker armature, an increment of the main current produces a greater increment in the field than in the armature reaction. With the same old Gramme machine run at about 18 amperes, an increment in the current produced a decrease in the potential difference both between the main brushes and the main and third brush. The armature reaction then became relatively larger than the increase in the field magnetism. But this old machine exhibits perfectly the property of governing by rocking forward the brushes on a diminishing load, with no more sparking in one position of the brushes than in another.

Hence it is clear that for practically sparkless commutation it is not necessary that the induction near but under the brush shall be a constant. The effective means by which, with constant current, the brushes can be set in any plane around the commutator cylinder is the reactive effect of the armature. This fact is brought out quite clearly by plotting the integrated potential differences between the upper or positive brush and the third movable one as ordinates to a horizontal line. The data are the same as were employed to plot the first curve in Fig. 1. If Fig. 2 is examined, a decided flattening in the curve will be found at 180deg., the position of the negative brush. The same flattening may be seen at 0deg. All curves, plotted with data obtained at different loads, show the same diminution or stay of the inductive process near the poles of the armature. The armature at these points paralyses the field. As the poles of the armature move around they sweep away the lines of force of the field, and only enough remain to produce an E.M.F. competent to offset the E.M.F. of self-induction, and, in addition, cause the newly-directed current to grow to its normal value as the coil passes out from under the brush.

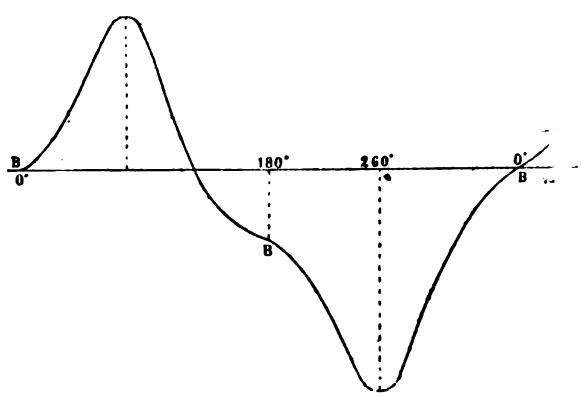

FIG. 2.

This reactive power of the armature may be utilised to effect approximately regulation for constant current without brush shifting. But for this purpose the load cannot be a maximum. The poles of the armature must be far enough forward to produce increase of magnetic leakage. As an example of what I mean, a 40-light machine had its brushes locked in such a position that it maintained 30 lights with 10 amperes current. Ten lights were then cut off, and then 10 more, with but small increase of sparking, and the ammeter showed an increase of current from 10 to 12 amperes only. A change of two amperes is within limits possible for practical lighting. The machine was then completely short-circuited by placing a large bar of iron across its terminals without dangerous sparking. This means that the characteristic of the machine beyond the crown of the curve approached a vertical line, the ideal characteristic of an automatic constant-current dynamo.

The conditions requisite for sparkless commutation of a constant-current machane are therefore quite clearly defined. The self-induction of the short-circuited coils must nearly balance the field in all positions of the brushes. Both Mr. Esson, in a paper before the British Institution of Electrical Engineers, and Prof. Ryan, in a paper before the American Institute of Electrical Engineers, lay down the condition that the brushes must be kept under the pole faces in order not to enter the weakened field between the pole corners. And yet I have seen constant-current machines working with the brushes beyond the extreme tips of the poles with no increase of sparking.

I do not regard this condition as absolutely essential, since at maximum E.M.F. the brushes may be moved through a considerable angle without appreciable change in sparking.

Prof. Ryan states in his paper above referred to, that "the magnetising force impressed by the field ampere-turns must be uniform at all points between the pole faces." This condition is favourable to sparkless commutation, but not essential. It has to do with the area of the sparkless position of the brushes for any given load. If the field is fairly uniform, this area will be about the same in different parts of the polar faces; if the field is far from uniform, sparkless commutation may yet be secured, but a smaller variation in the current will produce sparking than when the field is uniform, for the sparkless area on either side of the brush with a given external resistance is then much reduced. The region controlled by the armature poles is more limited in extent than when the field is uniform.

It follows that the single-magnet type of field is not suitable for a constant-current machine. This fact was remarked upon by Mr. Esson. For a two-pole machine the double-magnet type is to be preferred. If, then, the iron is reduced at the back opposite the middle of the polar surfaces, and the poles are thickened and rounded off rather blunt at the ends to prevent saturation, the field induction will be sufficiently uniform without the necessity of resorting to the chopping-away process applied to an English single-magnet machine described in Slingo and Brooker's "Electrical Engineering."

(To be concluded.)

NOTES ON A TRIP TO THE UNITED STATES AND TO CHICAGO, 1893.*

BY W. H. PREECE, C.B., F.R.S., PAST-PRESIDENT.

V. ELECTRIC LIGHTING.

(Concluded from page 147.)

The accumulator in America has been a failure for electric lighting, and a very strong prejudice exists against its use. It has led to much litigation, and the best forms seem little known there. The lagoons of the World's Fair grounds were, however, very successfully navigated by extremely pretty electric launches, worked and lighted by accumulators. The grounds at night, brilliantly illuminated and interlaced by winding waterways, with wooded islands and pretty bridges, along which illuminated gondolas and silent launches floated noiselessly, formed most beautiful and fairy-like scenes, superior to anything seen in Venice or pictured by art. The feature that distinguishes American from English practice is the persistent use of belting and countershafting. In some stations the belting was to English eyes appalling. Direct driving is only now making its way. There were several direct-driven engines and dynamos exhibited in the American section at the World's Fair, and some new stations now being built are to be direct-driven. The Willans and Robinson engines on show at the exhibition, and a steam-turbine exhibited in the Swedish section by Laval—a form somewhat similar to that of the Hon. Charles Parsons, who unfortunately did not exhibit—attracted much attention. The reports of our performances in England are much sought after, and I think one influence of the Chicago gathering will be to convert American engineers to direct driving. The elastic character of direct-driving engines, gradually increasing in number and capacity with the load, and the ability to shut down or turn on engine after engine as the load varies, are economical advantages of immense value. The rapid regulation of small engines, the much smaller space occupied where space is so valuable, the smaller capital expenditure involved, and the reduced working expenses, all give direct driving an advantage which should recommend itself to such eminently practical engineers as the Americans. The General Electric Company showed in the World's Fair a 1,000-h.p. triple-expansion vertical marine type engine, driving two 400-kilowatt multipolar dynamos, and the Chicago Edison Electric Light Company are fitting-up their new central station with direct-driving engines. The town work at such places as New York, Boston, and Chicago is as solid and substantial as anything we can show in England; but when we inspect the outlying works in country towns, we can only express our thanks that we

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

have the control of the Board of Trade and the protection of an Act of Parliament. It is the fashion to decry grandmotherly government, and to wince at departmental espionage; but the protection of life on our railways, the absence of accident in our electric light undertakings, and the character of the work done everywhere, as compared with the same conditions in the States, can lead to but one conclusion—viz., that if we are slower, we do these things at least better in England. It is all very well in the pioneer stage of any industry to let private enterprise have its full swing, but when an industry becomes a public necessity, and when the interests of the whole community are at stake, Government, as the custodians of the public weal, must step in and assume the control. The accidents in the States are terrible in their number and fatality, and they strike the observant Englishman with dismay. The value of life there seems to be very much below par.

VI. Electric Railways.

The progress made in the establishment of electric railways is the most wonderful instance of growth of electric industry observable in the States. In 1884 I found only one railway so worked, and that experimentally, at Cleveland. Now every town has its electric railway. There are 4,000 miles of line so worked, 6,900 motor cars, and 4,000 trailing cars.* The capital embarked is 13,000,000dol., and the rate of progress is scarcely checked by the serious financial depression that has passed over the country. Electrical appliances of all kinds for railway working were among the most conspicuous exhibits at the World's Fair. A special track was laid down for test and trial, and along here I inspected a 30-ton locomotive, the heaviest yet made, having a horizontal pull on the level of 6,000lb., or enough to draw 500 tons on an ordinary English railway. The type of railway in general use over the United States of America is very uniform. We have only one true example in England, and that is at Leeds. A modification of the system has, however, been adopted on the South Staffordshire tramways, and is about to be introduced in Coventry. The wires are all overhead. A heavy insulated copper wire is suspended over the centre of each pair of rails or "track," and called the "trolley" wire. This conveys the current from the power-house. It is picked up by a trolley rod, which presses, by the action of a spring, upon this wire, and so conveys the current to the motors, which are geared to each of the two wheel shafts of the car. The current is thence transmitted through the wheels to the rails, and it returns thence to the power-house by heavy copper returns buried in the ground or suspended on the poles. There are two very fine specimens of electric railways in Chicago. One, the Intramural Railway, conveying visitors to and from different parts of the grounds of the World's Fair, working very well, carrying an immense number of people, and financially very successful. It is not a trolley line, but it has a third rail acting as the main conductor. The other is the Chicago North Shore Street Railway, running to Evanstown. This is a trolley line, having iron poles of strong design and good taste. It is 7½ miles long, with a power-house situated in the middle of the line. It has 16 motor cars and 16 trailers. The feeders are carried on wooden poles, which are very unsightly. These feeders could have been more economically and more efficiently put underground. In the power-house they are using a simple horizontal reciprocating engine, driving a Thomson four-pole dynamo, fitted with carbon brushes, by means of continuous rope gearing. No sparking whatever is observed at the brushes, and nothing can work more smoothly; but the absence of condensing and the existence of rope gearing must render the engine part uneconomical. The maximum horse-power used is 246. The voltage varies with the load from 500 to 550. The current averages 200 amperes. The maximum number of cars on at one time is nine motors and nine trailers, and this averages at the power-station 13·7 h.p. per car running. The cars run on the straight at from 16 to 20 miles an hour. The rails are 85lb. per yard—a very heavy rail for a tramway. The usual rail is 52lb. per yard, as at Boston; but experience in the United States of America is leading to heavy rails. The pounding and hammering on the rails with heavy loads is very great, and in Philadelphia they are using even 90lb. rails. The trolley wire alone is not unsightly, but when it is protected with three guard wires, as at Boston, and the same poles carry the feeders, it becomes hideous, and it is astonishing that the American community submit to it. Such a system is impossible in England. This trolley wire must be elastic, otherwise the trolley itself frequently jumps off and stops the car. Attempts have been made to improve the appearance of the road by using handsome central iron poles, with solid brackets on each side to carry the two trolley wires, but the want of elasticity has introduced fresh evils. The trolley frequently comes off, and great sparking is evident. An admirable illustration of a modern electric railway is the electric *portage* between Lakes Ontario and Erie, from Chippewa to Queenstown, 13 miles long. It is on Canadian soil, and built with Canadian capital, but the work was done by an American firm. It is an open overhead trolley line, with iron posts and brackets. It is worked by water power derived from the Niagara Falls. The West End railway system of Boston is by far the most extensive electric railway system in any city in the States. In the power-station, which is situated on the harbour, there are 24 Babcock-Wilcox water-tube boilers, each developing 250 h.p. Surface condensing is used, sea-water being available for the purpose. There are six horizontal triple-expansion engines, each developing 1,000 h.p., and driving by means of belting 18 Thomson-Houston four-pole dynamos, all capable of being connected up in parallel, but put on and off as the load varies. The chimney is 252ft. high and 13ft. 6in. in diameter. It does not smoke, and the steam is generated so economically that only 11½lb. are used for one horse-power hour. There are three power-houses in Boston, the other two developing 2,000 h.p. each, so that there are 10,000 h.p. used in Boston for working their street railway system. The line is no longer run by contractors. It is entirely in the hands of the railway company itself. They have magnificent workshops, and a very fine staff. The chief engineer, Mr. Hirt, was extremely attentive and communicative. He supplied me with capital drawings of the works and general arrangements. The use of belting was again surprising; but I was told that a very large railway system at Brooklyn was going to be worked by direct-driven power, so as to obtain an authoritative and convincing trial of the relative merits of the two systems. I did not learn the type of engine to be fixed at Brooklyn, and I was unable to go there to find out. The track is light, as I have previously mentioned, but they are welding together the fishplates and the rails so as to obtain an electrically perfect return circuit. I saw the car and apparatus used for this welding process, but I could not see it in operation, for one essential part of the plant was being repaired. I saw the electric snow-ploughs used to keep the tracks clear in wintry weather. The system of railway working in Boston has given such satisfaction to the public that the traffic returns have improved 30 per cent. owing to the change from horses to electricity. The service is so much quicker, cleaner, and better performed. A railway car in full service is said to run an average distance of 250 miles a day, and its mean speed is 15 miles an hour. There is an important question under discussion in the United States of America—whether it is better to pursue the present practice of using two motors, one on each wheel axle, or to use only one motor connected electrically and flexibly with the wheels by bevelled gearing. This is the plan advocated and practically carried out by Mr. Sperry. The weight is thus placed in the middle. The horizontal pull is said to be greater. The starting torque is smaller. It is more easily controlled. There is no slip, and the velocity of all parts is uniform. It will climb a stiffer grade. One 35-h.p. motor replaces two 30-h.p. single-reduction Thomson-Houston or Westinghouse motors with economy of energy. The system is working in Pittsburg, where it was adopted after a very severe trial with a Westinghouse car, and it is about to be used on Twenty-second-street in Chicago. It has this disadvantage—that if the motor fails there is not a second one available to take the car home. The problem is an interesting one, and its solution will be watched with great interest, for it has an important bearing on the economies of our English roads. The feeling is pretty prevalent in the States that the conductors must eventually go underground. Experiments in this direction are being made in several directions, notably in Washington and Chicago. The trolley with its guard wires is really an abomination, and the disturbances created by insufficient return accommodation are annoying the telegraph and telephone interests, and alarming the gas and water companies. The future working must be metallic circuits and underground conduits. It is so done in Budapest, and it has been partially done in Blackpool and in Rome. Other experiments are contemplated in England. No one can doubt that the future of electric railways is very bright. The South London Railway and the Mersey Dock Elevated Railways are examples of great successes in England, but it is in the States, where this form of locomotion has become a necessity, that we are sure to see a speedy and practical solution of the problem.

* Trailing cars are not fitted with motors. They carry passengers only, and are drawn by motor cars.

Conclusion.

I have by no means exhausted the notes made during my trip, but I have said enough. Interviewing is a feature of American journalism that, thank goodness, has not taken root here. I was surprised to read of interviews with myself, extending to two or three columns, that resulted from the passage of a few compliments; but I was more surprised to find that statements supposed to have been made by me to an interviewer were taken *en serieux*. One irate functionary compared an official statement of our Postmaster-General with a mythical statement made by me, and triumphantly pointed out such a glaring contradiction as a complete refutation of my fallacies. I even read that I had stated that we electricians in England had nothing to learn from America. I have no recollection of ever having made any remark which could by any shorthand blundering have

Digitized by Google

been construed into such an absurdity; but if I had done so it would more likely have been one where "nothing" was a telegraphic error for "everything." I cannot too gratefully speak of the attention and kindness I received from everyone, and I certainly feel that I have personally profited from my visit very much indeed. A visit to the United States is something like charging an accumulator. It stores the visitor with energy. When I am discharged, and my adverse criticisms have been forgotten, I shall probably cross the Atlantic again.

PHYSICAL SOCIETY, January 26, 1894.

Prof. A. W. RUCKER, M.A., F.R.S., president, in the chair.

Mr. J. W. Kearton read a "**Note on a New Mode of Making Magic Mirrors.**" The author's first idea was that the magic properties were due to differences in reflecting power, but experiments showed this to be improbable, and indicated that the patterns visible by reflected light were due to slight concavities in the surface. Several methods of producing such changes of curvature were tried, such as electro-depositing and electrical etching, the plate being subsequently polished to remove sharp edges. The method found most satisfactory was to draw the figures on polished brass covered with wax, and etch them by immersing in nitric acid, subsequently scouring with charcoal, Sheffield lime, and swandown calico until all direct traces of the figures disappeared. The scouring rounds off the edges and makes the depressions concave, the two eventually forming one concave sweep, which makes itself visible when light is reflected from it on a screen. To obtain satisfactory results with figures having broad and narrow lines it was found necessary to paint over with hot wax the fine lines and the outer edges of the broad ones after the first immersion; a second immersion etched the middle parts of the broad lines deeper. By repeating the process, the broad lines were etched roughly concave in steps, and the scouring made the curvature continuous. Figures in relief, showing the patterns in shade on reflection, were obtained by painting the pattern on the plate in sealing-wax dissolved in naphtha, and etching away the uncovered portions by an immersion of one two seconds. A number of mirrors with patterns in intaglio and relief were exhibited to the meeting. **Prof. S. P. Thompson** said the chief interest of Mr. Kearton's work was that he had succeeded in producing mirrors by a process which Prof. Ayrton had found unsuccessful. The special polisher used by Mr. Kearton might have something to do with the result obtained. Some of the mirrors had been gilt after polishing and the reflected pattern improved thereby. **Prof. Ayrton** said he was greatly interested to see that mirrors could be produced by the chemical method. The polisher used by the Japanese was the flat end of a tight bundle of special straw cut crosswise. When the true explanation of the magic properties was found out, the chemical method was not pursued further. The **Rev. F. J. Smith** mentioned that he had produced magic properties on silvered glass by the inductoscript method. Although no markings could be seen directly, the pattern showed itself when light was reflected from the surface to a screen.

Mr. W. B. Croft, M.A., read a paper on "**Some Observations in Diffraction,**" and exhibited a large number of photographs of diffraction figures obtained under different conditions. The first series exhibited related to diffraction from parallel light (diffraction of Fraunhofer and Schwerd), and were obtained by placing various combinations of thin circular lines of light on a dark glass plate before the object-glass of a telescope focussed on a star. Spectral images of the star are formed by interference from the edges of the lines, thus giving diffraction patterns whose form depends on the shape of the aperture employed. The next series illustrated diffraction in shadow (Fresnel's diffraction), and were produced by condensing light on a minute pinhole, and placing the object between the hole and a microscope eye-piece. Beyond the eye-piece the camera used for photographing the phenomena was placed. Permanent records of remarkably good diffraction figures were obtained in this way, both of the combination of circles above mentioned and of various other objects and geometrical forms. After showing geometrically that diffraction bands from narrow obstacles and openings were wider than those from broader ones, the author explained the conditions necessary for making the bands visible, and pointed out the distinction between internal and external bands. Prominent amongst the photographs were several showing "Arago's white spot" at the middle of a shadow, and, in particular, this well-known phenomenon was shown as produced by so large an object as a threepenny-piece. Speaking of diffraction in a microscope, the author said little doubt need exist as to whether an image represented the real object or a diffraction modification thereof, for the latter were usually of a more misty and complicated character. Departing somewhat from the subject of diffraction, an excellent photograph of conically refracted pencils was shown, consisting of circular lines of light produced by passing light from pinholes through a crystal of arragonite. **Dr. Johnstone Stoney** thought the obtaining of permanent records of diffraction phenomena of great importance, and was particularly interested in the photograph showing conical refraction. **Prof. S. P. Thompson** said he had never seen diffraction effects exhibited to an audience so well before. He noticed that in several of the photographs Arago's spot was unintentionally shown to perfection in the shadows of dust particles. The **President** greatly appreciated the fact that the conical refraction photograph had been exhibited for the first time before the Physical Society.

A "**Note on a New Photometric Method and a Photometer for Same**" was read by **Mr. J. B. Spurge**. The method consists in using two diffusing screens (illuminated respectively by the lights to be compared) as secondary sources, and adjusting to equality the luminosity of equidistant internal surfaces by varying the apertures through which the light passes from the screens to those surfaces. By reducing the sizes of the apertures, the author has been enabled to compare lights of different colour; for when of sufficiently feeble intensity, coloured lights are indistinguishable from white or grey. The photometer is made up of two tubes, mounted at 45deg. to an axis, about which one of them is capable of rotating. When in the same horizontal plane the axes of the tubes form the sides of an isosceles right-angled triangle, at the middle of whose hypothenuse the light to be tested is placed; this illuminates one of the screens, whilst the standard light shines on the other. These screens used as secondary sources are situated a short distance away from the outer ends of the tube, whilst the inner surfaces of the near ends of the tubes are varied by means of a mirror. By turning the movable tube about the inclined axis and rotating the source about a vertical axis, the illuminating effect of the source in any direction can be tested. **Captain Abney** said the law of inverse squares was not true for weak lights, for the proportions in which the light from sources of equal intensity had to be reduced to appear white or grey depended greatly on the colour, being much greater for violet than for red. Only for the yellow-green rays was the ordinary law of illumination true when the intensities were feeble. **Mr. Blakesley, Prof. S. P. Thompson,** and the **President** also took part in the discussion.

LEGAL INTELLIGENCE.

GOLD TRUST COMPANY v. THE ELECTRIC TRAMCAR, LIMITED.

This motion was heard last week in the Chancery Division of the High Court of Justice, before Mr. Justice North. It was a motion in a debenture-holder's action to commit Alfred James Jarman, of 71, St. John's-hill, Clapham Junction, and Watson Smith, of 63 and 64, New Broad-street, to prison for contempt of Court in interfering with the receiver of the Court by having taken away from a certain shed accumulators and other property of the defendant company. It appeared that Jarman was a person who had been employed by the receiver and had a key of the shed. Watson Smith was manager of a company called the Elieson Accumulator Syndicate. He had contracted to buy from the receiver certain tramcars, accumulators, and plant for £250, and patent rights for £10, to be paid on delivery. He purported to sell the same chattels to the Elieson Accumulator Syndicate for £2,000, partly to be paid for in debentures. That company immediately contracted to sell the same property to a trustee for a new company for £15,000. The accumulators and some other goods were removed by Watson Smith with the aid of Jarman, without paying anything or leave from the receiver.

Mr. George F. Hart appeared for the plaintiffs in support of the motion.

Mr. J. W. Clark, for Jarman, pleaded that the conduct of his client was *bonâ fide*, though mistaken.

Mr. Watson Smith appeared in person.

Mr. Justice North made an order for the committal of both Jarman and Watson Smith. In the course of his judgment he observed on the difference of amount between the prices named in the three contracts. He could not say whether the price in one case was too high, or in another too low. That he had nothing to do with. Commenting on the evidence, he said he could not see anything *bonâ fide* in the conduct of the respondents; on the contrary, he might give it a very different name. As an order for committal was pressed for, he must make it.

COMPANIES' REPORTS.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY, LIMITED.

Directors: S. Wm. Silver, Esq., chairman; Abraham Scott, Esq.; Matthew Gray, Esq., managing director; Robert Henderson, Esq.; the Hon. Henry Marsham; A. Weston Jarvis, Esq.

Report of the directors for the year ending December 31, 1893, to be presented at the thirtieth ordinary general meeting of the shareholders, to be held at the Cannon-street Hotel, E.C., on Thursday, February 15, 1894, at 12 o'clock noon.

The annexed accounts show the net profit for the past year to be £94,607. 4s. 2d. Adding £46,844. 17s. 5d. brought forward, and deducting £25,000 interim dividend paid in July, there remains a disposable balance of £116,452. 1s. 7d. The directors have added £50,000 of this balance to the reserve fund, and recommend the distribution of a dividend of 10s. and a bonus of 5s. a share, free of income tax, amounting to £37,500, making, with the interim dividend, a total payment for the year of 12½ per cent., and leaving £28,952. 1s. 7d. to be carried forward. The Company's general business continues to increase. The cable for the Central and South American Telegraph Company mentioned in the last report was duly laid, and a few other cable manufacturing and repairing contracts were carried out during the year. The efficiency of the Silvertown and Persan factories is maintained. Mr. Scott and Mr. Henderson, the directors retiring by rotation, offer themselves for re-election.

NEWCASTLE AND DISTRICT ELECTRIC LIGHTING COMPANY, LIMITED.

Directors: John D. Milburn, Esq., chairman; the Hon. C. A. Parsons, managing director; Sir B. C. Brown; Colonel W. M. Angus; John B. Simpson, Esq. Jas. Patterson, secretary. W. D. Hunter, engineer.

Report of the directors to be presented to the shareholders at the seventh ordinary general meeting of the Company to be held at 57, Westgate-road, Newcastle-on-Tyne, on Monday, February 12, 1894, at 2.30 p.m.

The directors have pleasure in again reporting that the supply of current continues to give satisfaction to the Company's consumers. The installations connected to the Company's mains during the year are equal to 4,000 10-c.p. lamps, bringing the total up to about 18,500, and 388,422 units of electrical energy have been supplied, as against 290,469 units supplied in 1892. During the past year 3,308 yards of main and branch piping have been laid, together with 6,579 yards of main and branch cable. After some difficulty in carrying through the drift to the river, the condensing plant referred to in last year's report is now in operation, and although it has been working only about three months, a considerable saving has been effected in the consumption of fuel and water. The gross earnings during the year amount to £2,949.12s.3d., and after paying interest and making provision for reserve fund and depreciation, and writing off £100 from formation expenses, your directors are able to recommend a dividend at the rate of 3 per cent. for the half-year ending December 31 (less income tax), which, together with the interim dividend paid in July last, makes the dividend 5½ per cent. for the year. Mr. John D. Milburn and the Hon. C. A. Parsons retire by rotation, but are eligible, and offer themselves for re-election as directors. The auditors, Messrs. Strachan and Co., also offer themselves for re-election.

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING COMPANY, LIMITED.

Directors: Alfred Sohier Bolton, Esq.; Sir Frederick J. Bramwell, Bart., F.R.S.; G. H. Hopkinson, Esq.; Granville R. Ryder, Esq.; R. W. Wallace, Esq.

Report of the directors to be presented at the seventh ordinary general meeting to be held at 1, Great George-street, Westminster, on Thursday, February 15, at 5 p.m.

The directors submit to the shareholders a statement of the accounts of the Company, together with a report of the position of the undertaking at the end of the year 1893. The district of the parish of St. Mary Abbotts, Kensington, arranged to be purchased from the Chelsea Electricity Supply Company, Limited, was transferred to this Company in June last, the necessary statutory powers having been obtained. As far as can be judged from the experience of one half-year, there is every reason to anticipate a satisfactory result from this addition to the Company's area. The mains, which extended to a length of 13 miles on December 31, 1892, have been increased during the year 1893

Digitized by Google

to 16¼ miles—of which increase two miles are due to the new district and 1½ to the extensions of the Company's original system. During the year the number of houses and shops connected with the system has increased from 550 on December 31, 1892, to 734 on December 31, 1893; while the number of lamps calculated on the usual basis of 8 c.p. has increased from 47,441 to 64,529. Out of the total increase the new district represents 83 houses and shops, and 5,262 lamps Thus the increase on the Company's original district is 101 houses and shops, and 11,826 lamps. After paying the dividends on the 6 per cent. first preference shares to June 30, 1893, on the 5 per cent. second preference shares to September 30, 1893, and an interim dividend at the rate of 4 per cent. per annum on the ordinary shares for the first half of the year, the balance standing to the credit of the net revenue account for the year 1893 is £4,788. 7s. 9d. Of the above sum £1,456. 4s. 7d. has been appropriated for the payment of the first preference dividend to the end of the year, and £88 has to be set aside to meet the portion of the dividend on the second preference shares to the same date, leaving £3,244. 3s. 2d., out of which it is proposed to pay a further dividend on the ordinary shares, at the rate of 6 per cent. for the past half-year, making a total dividend for the year of 5 per cent. This will leave a balance of £1,059. 15s. 8d. No provision has been made in the accounts for directors' remuneration. In accordance with the articles of association, Mr. R. W. Wallace and Mr. A. S. Boulton retire from the directorship, and, being eligible, offer themselves for re-election. The auditors, Messrs. Lovelock, H. W. Whiffin, and Dickinson offer themselves for re-election.

BUSINESS NOTES.

Great Northern Telegraph Company.—For the month of January the receipts were £21,000.

Aberdeen.—The Town Council on Tuesday negatived a proposal to erect six arc lamps in Union-terrace.

Blackburn.—The Corporation seal has been fixed to contracts for electric lighting and other appliances.

Western and Brazilian Telegraph Company.—The receipts for the week ended February 2 were £3,207.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 4th inst. amounted to £632.

Westminster Electric Supply Corporation.—A dividend at the rate of 5 per cent. per annum for the half-year has been declared.

Direct Spanish Telegraph Company.—The receipts for the month of January were £8 more than for the corresponding period of 1893.

Cuba Submarine Telegraph Company.—For the month of January the receipts were £24 more than for the corresponding period of 1893.

Eastern Telegraph Company.—The receipts for the month of January were £64,851, as against £60,516 for the corresponding period of 1893.

West India and Panama Telegraph Company.—The receipts for the two weeks ended January 31 were £425 less than for the corresponding period of 1893.

Eastern Extension Telegraph Company.—For the month of January the receipts show a decrease of £3,363 as compared with the corresponding period of 1893.

Ruthin.—The town clerk has been directed to call a meeting of the Electric Lighting Committee, at which he would present the report he was directed to prepare.

Telegraph Construction and Maintenance Company.—The Board recommend a balance dividend of 15 per cent. making a total distribution of 20 per cent. for the year 1893.

Social Gathering.—The annual social gathering of the employés in the different departments of the Glasgow district of the National Telephone Company was held last week in the City Hall Saloon.

Coventry.—The Town Council have appointed Messrs. G. and I. Steane architects for the buildings of the electric light station, and they have been instructed to prepare plans and specifications with a view to obtaining tenders.

Milde Telephones and Electric Supply Company, Limited.—This Company has been registered with a capital of £20,000 in £1 shares to carry on the business of a telephone, telegraph, and electric light, heat, and power supply company.

English-Made Carbons.—The Atlas Carbon Manufacturing Company, Limited, of 17, Ewer-street, Southwark, S.E., draw our attention to the fact that they have for some years manufactured carbons for electric lighting, and also battery carbons.

Accepted Tender.—The tender of Messrs. S. J. Waring and Sons, at £228, has been accepted for supplying and fixing mahogany panelling and electric light fittings in offices, the Exchange, Liverpool, for Messrs. Clay, Medwood, and Co.

Digitized by Google

Beverley.—The clerk to the Local Board has laid before the Board estimates from two firms for making telephonic communication between the new infirmary and the workhouse. Eventually the Local Board agreed to leave the matter to be considered by the House Committee.

Forthcoming Wedding.—The marriage is announced to take place of Miss Beatrice Agnes Mary, daughter of the Rev. Charles S. Morgan, of Cape Town, South Africa, to Mr. Henry D. Wilkinson, on Tuesday, the 20th inst., at Christ Church, Crouch End-hill, at two o'clock.

City and South London Railway.—The receipts of the Company for the week ending February 4 were £951, against £956 for the same period last year, or a decrease of £5. The total receipts for the first half-year of 1894 show a decrease of £120 compared with those for the corresponding period of 1893.

Oswestry.—The Town Council have referred to the General Purposes Committee an amendment proposed by Alderman R. Lloyd, that the following streets only be left in the compulsory part of the Act for electric lighting: Oswald-road, Cross-street, Leg-street, Church-street, and parts of Willow-street and Salop-road.

Ballymena.—At a meeting of the Town Commissioners on the 5th inst., Mr. Burns moved a resolution that they should advertise in the local and Belfast papers, and also in the *Electrical Engineer*, asking for tenders to light the town from August 16 till May 16 either by gas or electricity. Mr. Graham seconded the motion, which was passed unanimously.

Sunderland.—In connection with the provision of the electric light at Sunderland, eight tenders have been submitted to the Highways Committee for the erection of the necessary buildings for the storage of the requisite plant. The highest was £4,053, and the lowest £3,167. The latter was from Mr. T. P. Shafto, Sunderland, whose quotation was accepted.

Dover.—The Town Council have received a report from Mr. Slings, electrical engineer, who had been asked to report on the proposed Board of Trade by-laws on electric light. Several small alterations were recommended, but the report principally was a strong objection to the proposed sanction of overhead wires. It was decided to forward the report to the Board of Trade.

Tenders Wanted for Dewsbury.—Tenders are invited by the 15th inst. for lighting the workhouse and premises by electricity, for the Guardians. Plans and specifications may be seen, and forms of tender obtained, upon application to Mr. Joseph Peace, clerk, Union Offices, Wellington-street, Dewsbury. The tenders are to be sent to the clerk, endorsed "Electric Lighting Tender," by the date stated.

Maidstone.—In accordance with the decision of the Local Board the Electric Lighting Committee have made enquiries in various quarters as to the terms upon which private firms or companies are prepared to carry out the installation of the electric light in Maidstone, and have received five offers. These were considered at a recent meeting, but no definite decision was arrived at, further information on certain points being deemed necessary.

New Installations at Liverpool.—Messrs. Bennett and Druce, 44, Fishergate, Preston, have lately completed an electric light installation at Messrs. Glazebrook and Rigby's, of Liverpool, including the whole of the extensive cellars owned by the firm. They have also wired the new offices of the Liverpool Grain Storage and Transit Company, Limited, and of Messrs. Clunie and Co., for connection with the Liverpool Supply Company's mains.

Tenders Required for Aberdeen.—Tenders are required by the 20th inst. for supplying and fitting up electric wiring and fittings for the Northern Co-operative Company's central premises. Copy of specification, schedule, and litho plans may be had from Mr. John Ferries, secretary, 54, Loch-street, Aberdeen, on receipt of 10s., which will not be returned. Tenders, marked "Tender for Electric Fittings," to be lodged with the secretary by the date mentioned.

Clerkenwell.—At the last meeting of the Clerkenwell Vestry the clerk read a letter from Mr. Sidney Morse, secretary to an electric lighting company, saying his clients desired to have certified copies of the recent resolutions passed by the Clerkenwell Vestry with regard to the extension of time. Because his clients were anxious to carry out the electric lighting in the district, he trusted that the Vestry would be good enough to formally give the extension of time asked. The letter was received.

Barrow-in-Furness.—The "Tea House," Ramsden-square, was lighted throughout by electricity for the first time a few days ago. The installation has been erected by Messrs. W. R. Thornton and Son, electrical engineers, Duke-street. The total light is equal to about 200 lamps, each of 8 c.p. The current is supplied by a "Castle" dynamo driven by a 6-h.p. (nominal) gas-engine. Both engine and dynamo are mounted on the same foundation, and being in the shop window, the machinery makes an effective show.

New Telephone Company, Limited, Manchester.—The third annual gathering of the staff took place on Friday evening last, the 2nd inst. There were upwards of 80 ladies and gentlemen present, including a considerable number of friends. The evening was a most enjoyable one, the songs and recitations given by various members of the staff and friends being much appreciated. The farcical sketch, "Wanted, a Servant," was cleverly performed by five of the lady operators. Dancing was indulged in until an early hour.

Manchester.—At a meeting of the Town Council on Wednesday Mr. Bax expressed a wish to have the electric light supplied to Stretford-road, and asked the chairman of the Gas Committee when that would be done. Mr. J. Brooks said that Stretford-road was at present outside the electric light arrangements, but no doubt as soon as Stretford-road or any other district made a demand for the supply of electricity for lighting purposes, and showed a prospect of a reasonable revenue, the Electric Light Sub-Committee would be prepared to undertake the work.

Grimsby.—An installation is being put up in the Prince of Wales Theatre. When the installation is complete there will be about 300 lights in the building. At present the exterior is illuminated by two arc lamps. The incandescent lamps for ordinary lighting are of 16 c.p., whilst those for lighting up the body of the theatre are equal to 25 candles. The footlights and orchestra jets are electrical, and the appearance and comfort of the theatre generally is much better than previously. The dynamo, fixed by Messrs. King and Co., of Hull, is driven by a 14-h.p. Tangye gas-engine.

Derby.—At a meeting of the Town Council on Wednesday, it was stated that the electric lighting station had been furnished at a cost of £143. 18s. 6d. The tender of Messrs. Siemens Bros., Limited, for additional engines, dynamos, main laying, has been accepted. The committee were not ready with their report respecting the staff required for working the electric lighting station. They had, however, appointed Mr. J. E. Stewart to be engineer and manager at the works, at a salary of £260 a year, and Mr. A. P. F. Moore as assistant engineer, at a salary of £2. 2s. per week. The report was adopted.

Kendal.—The Town Council have received a letter from Messrs. R. H. Fell and Sons, Limited, giving notice that with the approval and consent of the Corporation they proposed to apply to the Board of Trade for a provisional order to supply electricity for lighting and other purposes within the borough. Councillor Jefferys supposed that some time would yet elapse before it would be necessary to take any steps in the matter. The Town Clerk stated that July 1 would be the last day for sending in any applications. He took it as an instruction from the Corporation that at the proper time this application should be placed on the agenda.

Appointments Open.—The Blackpool Corporation, as stated in our advertisement columns, require for the tramways a resident working electrical engineer. The wages are 45s. per week. The person appointed must be a good mechanic, with sufficient practical knowledge to take charge of engines, dynamos, motors, and electrical fittings. Applications, in candidates' own handwriting, stating experience, and enclosing three recent testimonials, to be sent to Mr. T. Loftos, town clerk, before the 19th inst. The Edinburgh Corporation require a resident electrical engineer for the municipal electric light station. Further particulars are given in our advertisement columns.

City of London Electric Light Company.—Subject to the completion of the audit and after making the necessary provision for repairs, maintenance, renewals, and reserve funds, the directors, out of the profits for the year ended December 31, 1893, recommend the payment of the full dividend at the rate of 6 per cent. per annum on both issues of the preference shares of the Company, payable on and after the 23rd inst., carrying forward a substantial balance to next account. The Company give notice that the transfer books and registers of members will be closed for the purpose of preparing the preference shares dividend warrants, and for other business of the Company, from the 10th to the 24th February, both days inclusive.

Edinburgh.—The Electric Lighting Committee of the Town Council have opened the tenders for the works at the proposed central station at Torphichen-street. Between 30 and 40 estimates had been sent in, and these were remitted to a sub-committee for tabulation. On Tuesday, the Lord Provost's Committee of Edinburgh Town Council accepted estimates in connection with the electric lighting station at Torphichen-street, amounting in all to £24,300. The following are the successful offerers: Mr. George Sinclair, Leith, for boilers, etc., £6,042; Messrs. Siemens Bros, for engines, dynamos, pipes, pumps, etc., £15,098; the same firm for switchboard connections, etc., £1,760; Messrs. Crompton, Howell, and Co., London, batteries, £1,400.

Lighting of Bolton.—The Gas and Electricity Committee of the Corporation met last week, when tenders were ordered to be obtained for the supply and erection of two station meters at Lum street works. Notwithstanding the difficulties which have beset work of getting out the foundations for the new electric lighting works on Spa-road, much progress has been made. The circulars sent out by the committee to tradesmen and others asking for an intimation as to whether they wish to have light connected to their premises have not been very extensively replied to. An installation has been fitted up throughout the Town Hall corridors, and as soon as the light is ready the present gas fixtures and globes will be removed and substituted by artistic electric chandeliers.

Swansea.—The large premises of Mr. Brown are lighted throughout by electricity. The lighting has been designed by Mr. Brown with a view to efficiency and economy. The shop floor and windows are lighted by means of eight "Waterhouse" arc lamps of 2,000 c.p. The basement, offices, galleries, and showrooms are lighted by 113 incandescent lamps of 16 c.p., 25 c.p., 32 c.p., and 50 c.p. In addition to the arc and incandescent lamps used in the shop, there are two 6,000-c.p. lamps, one of which is underneath the glass roof and immediately over the well-holes in the shop and showroom floors, the other being run in the tower over the front entrance. The tower on the rear of the building has been specially erected to receive a powerful search-light projector of Admiralty pattern. The current for running the arc and incandescent lamps is generated in an engine-room in the basement. The plant consists of a Stockport gas

Digitized by Google

engine, of 16 b.h.p., driving an Elwell-Parker compound-wound dynamo.

Dublin.—The Corporation have deferred the consideration of the following resolution: "That the members now constituting the Electric Light Committee, with one member taken from each ward, not now represented on the Electric Light Committee, do constitute for the year 1894 a committee to be called 'the Lighting Committee'; that all the duties and powers of the Paving and Lighting Committees, of the Electric Light Committee, and of the Special Gas Committee, with respect to lighting, be transferred to and vested in the Lighting Committee; that the said committee may keep separate accounts and separately manage the electric lighting and the gas lighting, and report to Council at least once in every three months; that the members now constituting the Electric Light Committee shall co-opt to the Lighting Committee one of the members for each ward not now represented on said committee."

Lighting of the Guildhall.—At a meeting of the Court of Common Council a motion was proposed for the payment of the following bills to Michaelmas last—viz., the Gaslight and Coke Company, £160. 3s. 9d., and Mr. C. B. Ingram (for timber) £188. 2s. Mr. Morton asked for an explanation of the fact that, in spite of the introduction of electricity at Guildhall, the gas bill was so enormously high. Not getting a satisfactory answer, the hon. member moved that the bill for gas should be referred back to the committee for further consideration and report. Mr. Sayer having seconded this amendment, the City Surveyor explained that, although the electric light had been introduced at Guildhall, most of the offices were at the present time lighted by gas, the account for which was about £50 less than that for the corresponding period last year. Payment of the account was then ordered, Mr. Morton's motion being rejected.

The Steel, Iron, and Engineering Trades—In the trade report for 1893 issued by Messrs Bolling and Lowe, of 2, Laurence Pountney-hill, E.C., the following appears: "Another year has passed which has been a very disastrous one to many financial institutions in this country, as well as in Australia, the United States, and Southern Europe; in addition to this a revolution has occurred in Brazil—all of which has affected our trade to a vast extent. The steel, iron, and engineering trades have had to bear their share as the few following figures will show: Quantities and values of steel and iron exported for 12 months ending December 31, 1891, amounted to 3,240,146 tons, value £26,877,000; December 31, 1892, amounted to 2,739,279 tons, value £21,765,768; and December 31, 1893, amounted to 2,857,743 tons, value £20,614,155; but it is to be hoped that the year just commenced may see an increased demand upon our productive powers, and there are signs of this in the gradual recovery in the prices of all classes of pig iron, and in the fact that stocks of this article are comparatively insignificant."

Bristol.—St. George's Local Board have met to consider a Bill now being promoted in Parliament, entitled "A Bill to Authorise the Bristol Tramways and Carriage Company, Limited, to make Additional Tramways, and to Confer Further Powers upon the Company." The Chairman mentioned that as the Bristol Tramways Company were desirous of pushing on with their Bill, the meeting was convened with a view to furthering the matter. They had the Bill before them, but he hardly thought it worth while to read it, as the members knew pretty well the contents. They might depend upon it that Parliament would only sanction such conditions as would be compatible with the public interest. They were aware that in the Bill the tramways company sought powers to work an electric tramway through the parish of St. George by overhead wires. He moved that the Board give their consent to the Bill. Mr. Verrier seconded the motion, which was put and carried unanimously. The Chairman said the next matter to consider was if the Board would permit the trams being worked by overhead electrical wires. He moved that such consent be given. Mr. Coole seconded the resolution, which was carried. The Kingswood Local Board have passed similar resolutions.

Lighting of the Strand.—A long and exhaustive report was presented last week to the Strand Board of Works by the surveyor (Mr. A. Ventris) on the public lighting in the Strand district. He stated that he had made a careful survey of the streets and courts of the district, and was of opinion that the general lighting power of public lamps in the district compared unfavourably with the lighting power of adjoining and possibly less important districts. It was extremely difficult, without a considerable rearrangement, to suggest any increase in the number of lamps, and, moreover, an alteration in the position would give great dissatisfaction to those occupiers who had lamps now opposite their doorways; the removal would, in addition, involve disturbance of pavements, and a considerable expense in restoring them. An increase in the lighting power of existing lamps seemed, as a consequence, to be the only practical method of meeting the demand for more light. It was stated that improved lanterns gave, per feet of gas consumed, a greater light than was obtained in those of the old parish pattern, and those in use in the Board's district were possibly of the oldest type in London. He was unable to recommend, under the present system of supply, the extensive purchase and repair of costly lanterns. The gas company were at first unwilling to let, except on the hire-purchase system, the lanterns that they used, but now they had agreed to waive that objection and let them on the present scale of charge, if the Board would take them for seven years. With the present experience of electric lighting for narrow streets, its cost, and in his judgment its comparative failure for outdoor lighting, he apprehended that latter requirement was one to which the Board would offer no serious objection. It was agreed to remit the report and the whole question of lighting to the committee for further consideration and report.

Birmingham.—As mentioned in our last issue, the Market and Fairs Committee of the Town Council have for some time past had under consideration the subject of improving the lighting of the Market Hall. Messrs. Henry Lea and Thornbery, electrical engineers, have prepared a scheme for the lighting of the interior of the hall by means of 32 arc lamps of two sizes, of about 3,000 c.p. and 2,000 c.p. respectively, the several entrances to the hall being lighted by eight lamps of 2,000 c.p. each. From the result of the experiments made, the committee believe this number of lamps will be ample for properly lighting the hall and the several approaches thereto. The present cost of gas-lighting is about £535 per annum, and, with the additional overhead lanterns, the cost would be increased by about £65, making a total of £600 per annum, exclusive of the cost of lighting the exterior of the hall. The cost of providing and fixing and wiring for the above 40 arc lamps is estimated at £1,000, which sum could be borrowed probably for 10 or 15 years. The annual cost of the scheme would be as follows: Cost of providing and fixing and wiring 40 lamps, £1,000; interest and sinking fund, say, for 10 years, £120; electric light, £380; carbons, £25—total, £525 per annum. The cost of lighting the hall by electricity will therefore be less than the cost of lighting by gas, with far more satisfactory results. The committee have recommended that the scheme for the lighting of the Market Hall by electricity should be adopted, and that the Finance Committee be instructed to borrow £1,000 for providing the necessary lamps and fittings.

Extensions at Blackpool.—On Tuesday the Electric Lighting and Tramways Committee recommended the Council to borrow £24,000 for further extensions in the electric lighting of the borough. Councillor Pearson, in moving the adoption of the minutes, said the committee did not intend to spend the whole of the money in extensions. Three or four thousand pounds of the sum was wanted to pay for the over-expenditure on the last estimates. The committee proposed to spend immediately £15,000, and for future expenditure £5,000. The reason the estimates were exceeded was that a large stock of meters was purchased, and the lamp-posts on the promenade, instead of costing £9, had cost £11 each. A quantity of cable also made up the overspent estimates. Mr. Hammond had presented a lengthy report on the proposed increase in the electric plant. He called attention to the increased consumption and the lessened cost of production, and quoted figures to strengthen his argument. The results of the works had far surpassed the expectations of the committee. Councillor Fergusson seconded. Councillor Bickerstaffe proposed that the whole question of electric lighting be referred back to a meeting of the General Purposes Committee. They were given to understand that for an expenditure of £26,000 they would have a plant which would last them for a long time to come. He then went on to criticise Councillor Pearson's figures, and said that the loss on the actual work was £216, and no allowance had been made for repairs, rates, sinking fund, etc. Electricity was going to be a losing concern at Blackpool, seeing that the price was only 4½d. per unit, whilst in the large cities it was not less than 6d. per unit. Councillor Wildman seconded, and considered that the matter should be left over for 12 months. In reply to a long discussion, Councillor Pearson said the reputation of the town was at stake. He appealed to the Council to adopt the recommendations. The amendment was lost, and the original motion was carried.

Lighting of Chelmsford.—Some discussion took place last week at a meeting of the Town Council concerning the provisional order which Messrs. Crompton are applying for, and the draft of which has been considered in detail at two previous meetings. It appears that the town clerk had received a letter from Messrs. Deacon, Gibson, and Metcalf, solicitors acting in the matter for Messrs. Crompton, in which they declined to make the suggestions made by the Council on the terms of purchase, and submitted an amended draft, the effect of which was that if the local authority purchased at the expiration of 21 years, they should take such parts of the undertaking as were exclusively used for the public lighting of the town as a going concern, and not under the provisions of the Act. If the period of purchase was extended to 31 years, then the purchase must be as a going concern, without any compensation for compulsory purchase, and in the event of the term being extended to 42 years, the purchase would, of course be under the provisions of the Act. The Mayor suggested that a small deputation should wait on the Board of Trade to discuss this matter of the purchase clauses with Messrs. Crompton's representatives, but Councillor Britton remarked that at the previous meeting the Council had agreed to leave this matter in the hands of the Board of Trade. He did not favour the idea of a deputation, for it was divided on the subject, and therefore he desired that they should discuss the matter that evening, and he moved that the amended clauses as submitted by Messrs. Crompton should be accepted. Councillor Tanner agreed with Mr. Britton, while Councillor Taylor, in supporting the motion, said he failed to see what good could come of sending up a deputation to London which might misrepresent the intentions of the Council. Mr. Fawkes supported the motion, but Alderman Chancellor opposed it, arguing that the Council should have the right to purchase the concern at the end of 21 years or 31 years under the provisions of the Act. Councillor Whitmore approved of the amended clauses, and regarded them at reasonable. The motion was carried by a substantial majority. At a later stage in the proceedings Alderman Chancellor submitted that the resolution which had been adopted

Digitized by Google

was illegal, in view of the fact that it practically rescinded a previous resolution. Mr. Chancellor's objection was ruled to be in order, and the resolution in question was declared invalid. The matter was accordingly adjourned to the next meeting.

Messrs. Vaughan and Brown.—This firm, of 15, 16, and 17, Kirby-street, London, E.C., have every reason to be satisfied with their past year's record in the electric lighting department. They commenced the year well with Dr. Waugh's mansion, Wimpole-street, W.; Messrs. Faulkner's tobacco factory, Blackfriars-road; the Salvation Tavern, Newgate-street, and the Cambrian Stores, Glasshouse-street, W. They soon had these jobs under weigh and quickly disposed of, enabling them to turn their attention to the Blue Posts Hotel, Tottenham Court-road, and Challis's Hotel extension, The Tottenham, close to the Oxford, and The Chandos, coming in rapid succession. About this time they commenced the Hotel de Provence, a building at the corner of Leicester-square. This was only completed and opened a few months ago, many splendid fittings being specially designed for this building. The firm also installed the gas and the whole of the hot-water apparatus. Towards the summer Messrs. Vaughan and Brown were engaged on The Old King's Head, Old Jewry, the Horseshoe Hotel, Tottenham Court-road, and Old Paris, at the Earl's Court Exhibition, this proving a very successful job. The search-light used in the storming of the Bastille was supplied by them. At the Eastern Empire Theatre, Bow, an installation of about 600 lights was put in, together with a fine plant with 36-h.p. effective gas-engine. This was scarcely finished when they secured the contract for the Paragon Theatre, Mile End-road. This installation consists of about 1,000 lights, and is arranged with two complete plants, each with a 32-h.p. effective gas-engine. The engine-room had to be specially built, and this was done by Messrs. Vaughan and Brown, together with the hot-water heating, and the whole installation was executed in 25 days from the date of order. Following this came The George and Dragon, Shaftesbury-avenue; Messrs. Wylson and Longs, King William-street, Strand; The Duke of York, Germain-street, W.; the lighting of the Brewers' Exhibition, with 40 arc lamps, was next secured, with all the necessary plant for driving same, which consisted of a 50-h.p. gas-engine, dynamos, etc. More arc lamps being required at the Oxford, these were erected on the front of the building with excellent effect. Palace-chambers, Buckingham-gate, and the Confectioners' Exhibition, with 35 arc lamps and a 50-h p. gas plant, were next brought to a successful issue. Messrs. Harrod's stores new dining-rooms next claimed their attention, where some most handsome ceiling fittings were erected, and the large and extensive new offices of the company being entrusted to their care. The Stanley Show and Exhibition, with 50 arc lamps and a 50-h.p. gas plant, and the New Empire Theatre, Bristol, followed with 1 000 lights. Whilst engaged on this work they secured the lighting of The Don, a large clothing establishment in Bristol, with arc lamps. Then came the Cattle Show, with 55 arc lamps, and all the plant, including 50-h.p. gas-engine and dynamos. Great credit in carrying out the various installations is due to their superintending electrical engineer, Mr. G. C. Vaughan, jun., A.M.I.E.E.

Lighting at Leicester.—A special meeting of the Town Council was held on Monday for the purpose of considering the report of Mr. A. Colson, engineer of the gasworks, on the tenders received for the supply of engines required in connection with the electric light station which is being erected at the gasworks, and to which reference was made in our last issue. Mr. Colson, in his report, says: "On December 15, 1893, 10 firms were invited by the Gas Committee to submit tenders for the supply and erection at their central station, Aylestone-road Gasworks, of four horizontal compound condensing engines, three of which were to be of 300 brake horse-power each, and the fourth of 112 brake horse-power. The specification under which the designs for these engines were to be prepared stipulated that 'the governor must be capable of regulating the speed of the engine, so that without any adjustment by hand, whilst working, the speed at full load shall not be more than 3 per cent. less than with no load.' While complying with the conditions of the specification, the competitors were to submit what they considered the best mechanical arrangement for the purpose. Of the 10 firms invited, three declined to tender for reasons given. One tender was received too late for consideration. The tenders of the remaining six firms were opened by the Gas Committee on the 8th inst., and submitted by them to the Electric Lighting Sub-Committee for their consideration and report. At a meeting of the sub committee on January 10, I presented an analysis of the tenders received. Previous to the meeting I informed the chairman that after examining the drawings, specifications, and tenders in conjunction with the engineer of the Brush Electrical Engineering Company, there were in my judgment only two designs suitable for our purpose—viz., the design of Messrs. Musgrave and Sons, of Bolton, which provided engines for a total of 1.180 i.h.p., at the sum of £5,363, and an alternative design of Messrs. Hick, Hargreaves, and Co., also of Bolton, for engines equal to 1,185 i.h p., at the sum of £4,695. The tender of Messrs. Musgrave and Sons was exclusive of labourers required for the erection of the engines; the firm undertaking to supply skilled labour only, and that at a charge of 2s. 6d. per man per day extra to the amount of their tender. I strongly recommended the acceptance of the tender of Messrs. Hick, Hargreaves, and Co. as being the lower of the two. In going through the analysis of the tenders with the sub-committee, the chairman was pleased to refer in favourable terms to the design submitted by Messrs. Jessop and Son, of Leicester. This design, though good in many respects, I had been compelled to reject with others. In an accompanying letter Messrs. Jessop and Son stated: 'We have shown the engines with the dynamo placed between them, being the best way of distributing the strains, and the neatest arrangement. If, however, it is found necessary to apply the power at one end of the dynamo shaft, we can arrange our engines accordingly.' As it was not clear to the sub-committee whether the alternative design was offered at the same price, the firm was communicated with by telephone, and upon their replying in the affirmative, permission was given them to submit drawings of their proposed rearrangement. It is this design and tender marked No. 9 in the analysis, as compared with that submitted by Messrs. Hick, Hargreaves, and Co., and marked No. 7, that I have your instructions to report upon. In general arrangement the designs are similar, inasmuch as side by side engines, placed on one side of the dynamo, are provided for in each case. As to the large engines, they are equal as regards diameter of cylinders and length of stroke, but those offered by Messrs. Hick, Hargreaves, and Co. are to indicate 350 h.p. each, at a cost of £3,945, while those offered by Messrs. Jessop and Son are to indicate 340 h.p. each, at a cost of £4,035. In the former case the engines would be supplied with Corliss valves and gear, and in the latter with Collmann's. Even without claiming any advantage for the additional indicated horse-power this comparison shows a difference of £90 in favour of Messrs. Hick, Hargreaves, and Co.'s tender, added to which the engines are supplied with a more costly and well-proved valve gear. The following are the particulars as regards the small engine offered by each firm:

Firm.	I.H.P.	Revolutions.	Size of cylinder.		Stroke.	Description of valve gear.	£
			in.	in.	in.		
Hick, Hargreaves, and Co.....	135	118	11	20	24	Corliss	750
Jessop and Son ...	125	118	10	18	24	Hartnell	610

From this comparison of the small engines there appears to be an advantage of £140 in favour of Messrs. Jessop and Son, but this amount would be more than equalled by the gain of the additional horse-power, and the extra value and superiority of the valve gear provided for in the engine offered by Messrs. Hick, Hargreaves, and Co. I am thoroughly acquainted with the character of the work executed by each of the firms referred to, and after giving the most careful further consideration to this matter, I am bound to advise you (as I have already advised the Electric Lighting Sub-Committee and also the Gas Committee) to accept the tender of Messrs. Hick, Hargreaves, and Co, as by so doing you will be obtaining greater value for your money, and will be entrusting a difficult and responsible piece of work to one of the most experienced and competent firms of engineers in the kingdom. In conclusion, I may be permitted to point out that the Gas Committee, in adopting slow-speed direct-acting machinery in connection with their electric lighting station, are following continental rather than English practice, and that the successful working of this system abroad has only been achieved by the use of engines of the most perfect design and workmanship." Correspondence and the analysis referred to are appended to the report. On the presentation of the report, considerable discussion ensued. Alderman Lennard moved that the tender of Messrs. Hick, Hargreaves, and Co. for the erection of electric light engines at the sum of £4,695 be accepted, and that the contract be sealed with the common seal of the borough. Councillor Faire seconded the motion. Councillor Marshall moved as an amendment that Messrs Jessop's tender be accepted. Councillor Woolley seconded the amendment. Eventually the amendment was lost and the motion was adopted.

Newport Electric Lighting Scheme.—The following letter, under date January 27, has been addressed to the Newport town clerk by Messrs. Crompton and Co.: "Following on yesterday's visit of your committee to our Chelmsford works and to the Kensington lighting station of the Kensington and Knightsbridge Company, we beg to offer some remarks, which we think should be laid before your committee at the present time. We tendered to your specification for the supply of high-pressure electric plant for Newport lighting, and our tender for the complete plant was the lowest of those sent in. Certain objections were raised by your committee, acting on the advice of their engineer, which were to the effect that our tender, though apparently lowest in cost, did not offer plant of equal value for the intended purposes to that of one of our competitors. We have endeavoured to meet these objections by showing you that there is no foundation for them, that not only have we had considerable and very satisfactory experience in the manufacturing and in the working of high-pressure plant, but that the financial results of our Chelmsford undertaking are equal to, if not superior, to the most successful high-pressure installation which has been at work for a sufficient time to enable a fair judgment to be made as to its efficiency and working cost. On these grounds we beg your committee to reconsider their proposal to pass over our tender in favour of one which involves a greater expenditure of your money. If we are successful in this, we are confident of supplying you with plant which will compare favourably in every respect with any lighting plant that has hitherto been set to work on the high-pressure system. We have gathered from our conversation with the various members of your committee that you are under the impression that we, as engineers, are in complete agreement with your committee's decision to adopt high-pressure lighting, and that your engineer claims that he has converted Mr. Crompton to his way of thinking. We most emphatically deny this. We have never been called upon to express an opinion on this point; we have confined ourselves solely to offering you the best plant required by your specification. As we understand that our silence on this point may be misconstrued, we now beg to state

Digitized by Google

that from the very first we have formed an opinion that the area to be lighted at Newport is not sufficiently extensive to warrant the use of high-pressure plant, which is admittedly more costly to work. We feel confident that there will not be any saving, even in capital expenditure, by the adoption of the high-pressure system, and the works cost in such a town as Newport will be 50 per cent. higher on the high-pressure system than they would on the low-pressure one; now that we have visited Newport several times, and walked over the ground and examined the maps of the streets which you propose to light, we are prepared, if we were asked to do so by you, to submit a proposal to design and construct plant on the low-pressure system for a sum which, exclusive of buildings, would not exceed £19,500, and thus would involve a capital expenditure £3,000 less than that which you now contemplate. Our proposal would also include estimates or schedules for extensions throughout the whole of the area included in your provisional order. Further than this, in such a case we should be prepared to take upon ourselves all risks and responsibilities regarding the cost of working these works for any term of years that you may desire. One method of doing this is based upon a sliding-scale of prices at different rates of output, and we enclose a sliding-scale at which we should be ready to work in Newport. Examining this scale you will see at even a very moderate output, apart from the public lighting, of say 100,000 units per annum, there would be a fair margin, after allowing for interest and redemption fund, for the Corporation between the price we ask and the price the Corporation would easily obtain; we consider that in Newport 6d. a unit would be a fair price to charge. Under this scheme, therefore, the town would be relieved of responsibility of working or risk of loss, and yet would own the works, and could thus avoid the possibility of the electric supply becoming a monopoly; they would also be actually receiving profits from the electrical undertaking. We have mentioned above an output of 100,000 units per annum, because we are sure that such a demand will be rapidly and easily reached in Newport probably within 12 months from starting. The second method is: (1) We contract for the necessary works for you as proposed above at £19,500, with schedules for extension; (2) we pay you as annual rental for the use of the works a sum equal to the interest that you have to pay for the money expended thereon; (3) also such further sum per annum as it would be necessary to put aside as a sinking fund to clear off the loan for the electric works in the time which is covered by the provisional order; (4) also we undertake to give up 10 per cent. of the profits which we may succeed in making annually; (5) also we undertake to give special terms for the current required for public lighting. It is, of course, understood that we should be able to give substantial guarantees of our financial ability to carry out our part of the arrangement, and that the Corporation would have the right to terminate the lease of the works to us at any time after a certain fixed period by giving sufficient notice of their intention. We have had little time since our conversation of yesterday evening to formulate these proposals, but we think that we have said enough to put clearly before you what are our views, and what are the responsibilities that we are prepared to undertake, and to show you that we are prepared to support our opinion on commercial lines. Should either of these suggestions be approved by your committee in principle, we shall be glad to meet them and discuss the approved scheme in regard to details, many of which would want carefully considering. Awaiting the favour of your reply, we remain, yours faithfully.

NOTES.

Guildford.—The lighting question has not yet been definitely settled.

Telephony.—A scheme is on foot for connecting Vienna and Odessa by telephone.

Dance.—The engineering staff of the Blackpool Corporation electricity works have just had a successful "hop."

Glasgow Tramways.—The tramcars which will be taken over by the Corporation in July are to be lighted by electricity.

The "Pall Mall Gazette" and Mr. Harness.—Mr. Harness has withdrawn his action for alleged libel against the *Pall Mall Gazette.*

Iron and Steel Institute.—It has been decided to hold the autumn meeting of the Iron and Steel Institute at Brussels from September 4 to 7.

Madras Electric Tramways.—It is stated by a Madras paper that friction has arisen between the directors and some of the local shareholders.

Paddington.—A special committee has been appointed by the Paddington Guardians to consider and report upon the proposal to light the infirmary by electricity.

Harbour-Lighting.—The Rothesay Harbour Trust and Town Council have authorised a committee to take steps as might be necessary for lighting the harbour with the electric light.

Acton.—The Local Board have instructed the surveyor to make enquiries as to the probable cost of having a system of electric fire alarms and electric calls for the firemen established in Acton.

Obituary.—Mr. John Galloway, head of the firm of engineers now known as Galloways, Limited, died on Sunday night, in his ninety-first year. He was regarded as the "father of the iron trade" in the Manchester district.

Lighting in Westminster. — The Westminster Electric Supply Corporation, who in December, 1892, supplied current to an equivalent of 98,686 lamps of 8 c.p., are now furnishing 134,268 lamps, and applications have been received for over 9,000 more lamps.

Students of the Institution.—A students' meeting of the Institution of Electrical Engineers will be held this (Friday) evening at 28, Victoria-street, Westminster. Discussion will take place on Prof. Forbes's paper on "The Electrical Distribution of Power from Niagara Falls."

Society of Arts.—On Tuesday, at 8 p.m., a paper on "The Arts and Industries of Belgium and the Antwerp Exhibition, 1894," by M. Edouard Sève, will be read. On Wednesday, at 8 p.m., Mr. W. H. Preece, F.R.S., will present a paper on "Electric Signalling Without Wires."

Private Bills.—In addition to the numerous private Bills by railway companies and other corporations which have been deposited in Parliament, it is mentioned that 17 water companies, five gas and water companies, and 16 gas and electric lighting companies are asking for further powers.

Chiswick.—The Local Board have received communications from the Board of Trade in reference to the amendments suggested by the Board as to the proposed regulations for electric lighting in Chiswick. The Board of Trade has substantially adopted the opinion of the Local Board and the surveyor.

Missenden.—The village of Missenden, Bucks., was illuminated by electric light on Tuesday evening, the Vestry having entered into agreement with an electric lighting company to light the streets during the winter months This is the first place in the county that has adopted the electric light for street illumination.

"British Locomotives."—The first edition of Mr. Bowen Cooke's work on "British Locomotives" has sold so rapidly that the publishers announce a second and revised edition as almost ready for issue. The same publishers (Whittaker and Co.) announce a work on "Surveying and Surveying Instruments" by Mr. G. A. T. Middleton.

"Electric Light Installations."—The second volume of Sir David Salomons's "Electric Light Installations" (seventh edition), dealing with apparatus, engines, motors, governors, switches, meters, etc., will be shortly issued in Messrs. Whittaker's "Specialist's Series." The third and concluding volume is now in the press, and will deal with the application of electricity.

The Institution.—An ordinary general meeting of the Institution of Electrical Engineers will be held on Thursday next, the 22nd inst. A paper by Mr. Gisbert Kapp, M.I.C.E., member, "On a Method of Testing the Magnetic Qualities of Iron" will be read. A "Note on Parallel Working Through Long Lines," by Mr. W. M. Mordey, member, will also be presented.

Lecture.—The next meeting of the Hammersmith Literary and Scientific Society will be held to-morrow (Saturday), at eight o'clock, at the Vestry Hall, Hammersmith Broadway, when Mr. Julius Maier, Ph.D., will deliver a lecture entitled "Disinfection, with Special Reference to Electrolytical Methods for the Purification of Sewage." The lecture will be illustrated by experiments.

Telephony.—The Highways Committee of the London County Council have considered an application made by the Home Telephone Company for permission to place a telephone cable in the subways from 85, Queen Victoria-street to Charing Cross, and along the whole length of the subway in Northumberland-avenue. The committee recommended that permission be given on certain conditions.

Central London Railway.—The shareholders in this company have passed a resolution approving the Bill in Parliament extending the time for the purchase of lands and completing the railway. The Bill proposed that the time for purchasing land in respect of the whole undertaking should be extended to 1897, and until 1900 for completing the works. It is intended to adhere to electricity as the motive power.

Royal Meteorological Society. — An ordinary meeting of the society will be held at 25, Great George-street, Westminster, on Wednesday next, at 8 p.m. Papers will be read on the following: "Temperature, Rainfall, and Sunshine at Las Palmas, Grand Canary," by Mr. J. Cleasby Taylor, M.D.; "Report on the Phenological Observations for 1893," by Mr. Edward Mawley, F.R.Met.Soc.; and "Comparative Observations with two Thermometer Screens at Ilfracombe," by Mr. William Marriott, F.R.Met.Soc.

Lighting of Petroleum Vessels.—In the course of a paper read last week before the Institution of Civil Engineers, on "The Transport of Petroleum in Bulk," Mr. Boverton Redwood, A.I.C.E., stated that the chief risk occurred during loading and discharging. The vessel should, except as regards the necessary marine lights, be lighted only by electric incandescent lamps, the ship being carefully wired, the positions of the switchboards being judiciously chosen, and any lamps used in spaces liable to become charged with vapour being of safe construction.

Station-Lighting.—A further extension of electric lighting has just been completed at the new Caledonian Station, Edinburgh, and the whole of the platforms and offices, so far as they are completed, are now lighted by electricity. Seven arc lamps of 2,000 c.p. have been

Digitized by Google

erected in the shunting and goods yard. The goods-sheds, offices, and signal-boxes have also been provided with about 400 16-c.p. incandescent lamps. In the lighting of the station gas has been entirely dispensed with. The work has been executed by the railway company's electrical staff under the supervision of Mr. Dunn, the superintendent of telegraphs.

Exhibition of Meteorological Instruments.—The council of the Royal Meteorological Society have arranged to hold at 25, Great George-street, S.W., from April 10 to 20, an exhibition of instruments, photographs, and drawings relating to the representation and measurement of clouds. The Exhibition Committee invite co-operation, as they are anxious to obtain as large a collection as possible of such exhibits. The committee will also be glad to show any new meteorological instruments or apparatus invented or first constructed since the exhibition in 1892, as well as photographs and drawings possessing meteorological interest.

Laying of New Mains.—The London County Council on Tuesday granted permission to the Charing Cross and Strand Electricity Supply Corporation to lay a 1in. pipe containing pilot wires from the end lateral of the Northumberland-avenue subway to the office of the Boy Messengers', etc., Company in that thoroughfare; to the House-to-House Electric Light Supply Company to place mains in Rosary-gardens on the east side; to the Westminster Electric Supply Corporation to lay mains (*a*) across King-street, Westminster, and (*b*) from the north-west corner of Carpenter-street, along Mount-row, to Davies-street; and to the Crystal Palace District Electric Supply Company to place mains in Sydenham-hill-road from High-street to Eliot-bank.

Electric Traction at Howth.—The proposals to construct an electric tramway on the north side from the terminus of the United Tramway Company at Dollymount to Howth, and on the south side from Clonskeagh terminus to Dundrum and Windy Arbour, show that the people of Dublin are awakening to a full sense of the importance of electricity as a motive power. Their present alertness is, no doubt, due to the fact that the Dublin Southern Tramways Company have succeeded by quietly energetic and businesslike persistency in obtaining parliamentary powers for the construction of an electric railway through the whole extent of their present district from Haddington-road to Dalkey, and as soon as the required capital is subscribed the work will be commenced.

Electric Light in the City.—The City of London Electric Lighting Company report that the street work is now approaching completion. On February 1, 580 miles of "ways" had been laid in the City in 55½ miles of streets, through which 105 miles of cables had been drawn. Sufficient "ways" have now been laid down to supply a demand of 400,000 8-c.p. lamps installed. As regards private lighting, nearly 1,300 private consumers, representing a total of 72,000 8-c.p. lamps, are now being supplied with current from eight transformer stations, and during the current half-year it is expected that the whole 22 stations required for the entire City will be at work. Applications, the directors add, continue to come in satisfactorily, the total received to date being equal to the supply of current for 100,000 8-c.p. lamps.

The Dangers of Electric Wires.—In the House of Commons on Monday, Mr. Weir asked the President of the Board of Trade whether his attention had been drawn to a serious accident which occurred in a public street in Bournemouth, by which one horse was instantly killed and another seriously injured, and the lives of passengers endangered who were in the omnibus to which the horses were attached; whether the accident was caused by a leakage of high-tension electricity from the electric wires laid under the street; and whether steps would be taken to prevent similar accidents occurring in the streets of London. In reply, Mr. Mundella said that the electrical adviser of the Board of Trade was instructed on the day of the accident to make enquiry on the spot. He would be happy to hand to the hon. member a copy of the report which disclosed the inspector's opinion of the probable causes of the accident. The Board of Trade are now considering whether any additional regulations are necessary in order to prevent similar accidents in future.

Traction at Bristol.—The Chairman of the Bristol Tramways Company, Mr. W. Butler, mentioned last week to the shareholders that the directors could recommend the introduction of the overhead trolley system between Old Meeting-street and Kingswood-hill. The accumulator method had been tried probably for the longest time at Birmingham, where one of the sections of the Central Company's system was worked in this way. As the result of a thorough test under the best possible conditions, the system had been found excessive in cost and uncertain. Mr. Butler stated that the authorities representing three-fourths of the length of the route, had already signified their unanimous approval of the Bristol Company's proposals. This had been done after an inspection by the members of the local authorities of a similar installation at Walsall, Darlaston, and Wednesbury, the deputations returning fully impressed with the great advantages which must accrue to their constituents by permitting the company to introduce it in their districts.

Polarisation of Platinum Electrodes in Sulphuric Acid.—Mr. J. B. Henderson, in the *Proceedings* of the Royal Society, refers to experiments in this direction. Of two platinum electrodes immersed in sulphuric acid and connected with the primary circuit, one was also connected with the earth, and the other through a key with one pair of quadrants of an electrometer. Connected with the same pair of quadrants, through another key, was the slider on a bridge with a special battery. The other pair of quadrants and one end of the bridge were earthed. The slider was so moved that the permanent deflection it gave on the electrometer was not disturbed when the primary circuit was broken and the polarised electrodes connected with the instrument. The potential of the quadrants was then that of the polarisation. The mean value of the E.M.F. of polarisation determined in this way was 2·09 volts, the primary current varying from 0·2 to 1·0 ampere, the time of its passing from 25 minutes to 18 hours, and the strength of the solutions from 5 to 30 per cent. The extreme values were 2·05 and 2·14.

Refuse as Fuel.—On Saturday a party, including engineering experts, sanitary officers, and others interested, journeyed to Halifax, at the invitation of the directors of the Atlas Contracting Syndicate, Limited, to see the Livet process of burning rubbish for the production of motive power. The party were received at the works by Mr. Edwin E. Glaskin, C.E., the consulting engineer to the company, in the engine-room, which was lit by several arc lamps, the steam power being supplied by the Livet boiler. Near the furnace doors was a large heap of unsifted refuse. The furnaces were fed solely from this heap, and in spite of its unpromising nature, no smell whatever is said to have been apparent, nor was any smoke visible from the furnace shaft. Details as to the construction and working of the furnace were given by Mr. Glaskin. He said that the average quantity of rubbish burned per hour on each square foot of grate surface was 33lb., and

Digitized by Google

four separate tests, made in the presence of independent engineers, show that 4·081b. of water were evaporated per pound of rubbish consumed. The steam generated can be applied to purposes other than electric lighting. The town refuse of London, Mr. Glaskin states, would produce by this process over 87,818 i.h.p. at a total cost of £141,499, whereas the cost with the best Lancashire boiler, burning coal and evaporating 10lb. of water per pound of coal, would be £799,143.

Electric Lighting of Londonderry.—The Corporation have again discussed the scheme for lighting the city by electricity. The cost was originally estimated at £12,000, and was afterwards increased to £15,000, but now, when the works are approaching completion, it has been discovered that £25,000 will not be sufficient to carry out a complete and satisfactory scheme of illumination. The meeting held on the 9th inst. was convened on a requisition sent to the mayor and signed by six members of the Council. Councillor Hastings proposed a resolution that they should get powers to borrow a supplementary loan of £5,000 in order to finish the cost of lighting 170 arc lamps. Councillor Young seconded the motion. The debate was then carried on with great animation, and an amendment was proposed by Councillor Harper, and seconded by Councillor Caldwell, that having regard to the excessive expenditure already incurred in connection with the electric lighting scheme, and having regard to the absence of any reliable information touching same, it is resolved not to apply for any further loan in connection with the scheme. On a division the amendment was lost by 13 votes to 6. Councillor Babington then moved, and Councillor Thompson seconded, a further amendment, that £3,500 be applied for; and on a second division this amendment was also defeated. The original motion, to borrow an additional £5,000, was then put to the Council by the Mayor, and carried by 10 votes for to 8 against.

The Waterloo and City Electric Railway.—When the shareholders of the London and South-Western Railway Company had disposed last week of the ordinary business of the company, the meeting was made special for the purpose of considering *inter alia* an agreement between the company and the Waterloo and City Railway Company, incorporated by the Waterloo and City Railway Act, 1893. Mr. Wyndham S. Portal, the chairman, explained that this was an important matter. The railway, running as it would from Waterloo to a terminus near the Mansion House, would be an immense convenience to persons using the South-Western Railway and having business in the City. There would be no intermediate station, and passengers would be conveyed in the space of about four minutes. He also mentioned the interesting fact that this project had been talked of ever since 1846, but had always been abandoned because the South-Western had never seen their way to get to the City under three or four millions of money. Now science had come to their help, the capital for making the line being estimated at £540,000. It was proposed to raise the money in £10 shares bearing a minimum dividend of 3 per cent. The directors felt certain it would be a remunerative undertaking, and the proprietors of the London and South-Western would have priority in the allotment of shares. In a short time tenders would be invited for the construction of the line, and it was expected that the work would be completed in two and a half or three years. The proposed agreement was authorised to be entered into.

The Removal of Telephone Wires.—Judgment has been delivered by Mr. Justice Kekewich, in the Chancery Division, in the action brought by Keith Prowse and Co., Limited, against the National Telephone Company, Limited. It was a motion on behalf of the plaintiffs to restrain the National Telephone Company, their servants, or workmen from cutting or disconnecting the telephone wires connected with the plaintiffs' premises. From the statements of counsel, it appeared that on July 1, 1889, the defendants entered into an agreement to supply the plaintiffs with telephone communication, the plaintiffs paying a certain rent. That agreement came to an end, but defendants continued to supply the wires, the plaintiffs continuing to pay the rent. On December 30, 1893, the defendants gave the plaintiffs notice to terminate the agreement forthwith, and demanded the rent up to December 31, and gave notice of their intention to disconnect the wires. Plaintiffs then issued the present writ, and gave notice of motion. Mr. Justice Kekewich said as no question arose as to erection of the wires, the question was one of the maintenance. The company might not be compelled to maintain the wires, but it was the essence of the agreement that the wires should be open to the use of the plaintiffs, and the defendants could not be allowed to cut them off. In his Lordship's opinion, by the conduct of the parties a yearly tenancy had been constituted, which the defendants could not be allowed to terminate by an immediate notice. He should grant an injunction to restrain the defendants from interfering with the wires pursuant to their notice until trial or further order, the cost to be costs in the action.

Action of the Electric Arc on the Diamond, etc. M. H. Moissan, in the *Compt. Rend.*, deals with the action of the electric arc on the diamond, amorphous boron, and crystallised silicon. In the electric arc, at a somewhat high temperature, the diamond becomes incandescent, swells up without melting, and becomes covered with black masses consisting entirely of hexagonal lamellæ of graphite, which is easily converted into graphitic oxide. If the diamond is placed in a small carbon crucible in the electric furnace previously described, and is subjected to the action of an arc produced by a current of 70 volts and 400 amperes, the crystal first breaks up into small fragments along the planes of cleavage, and then at a higher temperature swells up and is completely converted into graphite, which yields yellow graphitic oxide. It follows that at the temperature of even a moderately intense electric arc, the stable form of carbon is graphite. When heated in a carbon envelope at the temperature of the oxy-hydrogen blow-pipe, the diamond is covered with an adherent black mass, which slowly dissolves in a mixture of potassium chlorate and nitric acid, but which is not graphite. Amorphous boron, prepared by means of magnesium, volatilises without fusion in the electric arc, the extremities of the electrodes being converted into partially-crystallised boron carbide. Crystallised silicon, when heated in the arc, first melts and then boils, the extremities of the electrodes at the end of the experiment being covered with pale green crystals of carbon silicide. The phenomena in the arc were observed by projecting on a screen by means of an intense arc an image of the arc of lower intensity in which the substances were heated.

The Use of Cupric Nitrate in the Voltameter.—A paper by Mr. F. E. Beach is given in the *American Journa of Science* on the "Use of Cupric Nitrate in the Voltameter and the Electro-Chemical Equivalent of Copper." The object of this paper is to show that cupric nitrate has some marked advantages over the sulphate for use in the voltameter. The nitrate solution freshly prepared has a tendency to dissolve copper, which decreases, however, after the copper electrode has been kept in the solution for a sufficient length of time. Another difficulty is due to oxidation of the copper deposited, which may be prevented by the addition of a small amount of ammonium chloride.

Digitized by Google

The following method is recommended for the preparation of the solution: Dissolve copper nitrate, the purest obtainable, in distilled water. Boil for a short time to expel the air, and keep at a temperature of 100deg. for an hour or two in the presence of bright metallic copper in order to completely neutralise the solution. When ready for use it should have a density of about 1·53. Add a saturated solution of ammonium chloride at about the rate of one drop to 100 c.c. of the nitrate. It is not easy to specify the proper amount of ammonium chloride necessary, and the surest way is to try a preliminary experiment. If too much be present, the deposit will discolour on drying; if too little, the deposit will oxidise in the solution. The weight of copper deposited does not appear to depend on the current density, and is practically independent of the temperature between 10deg. and 35deg. The equivalent obtained for copper, using the nitrate, agrees very well with that calculated from the best chemical determinations.

The Society of Engineers.—Mr. George A. Goodwin, the president for the present year, delivered an inaugural address before the society on Monday, dealing with the present position and practice of mechanical engineering. Boilers being the most usual form of apparatus whereby motive power is obtained to put all machinery in motion, he naturally dealt with them first, pointing out rapidly the growth up to the present types—viz., Lancashire, Galloway, marine, locomotive, and water-tube, etc.—and mentioned the chief points in each, both in construction and working, and recommending mild steel of a certain quality, and properly tested for strength, ductility, and temper. Passing on from steam-engines, the author described the many improvements made in internally-fired engines (gas and oil) in recent years, culminating in the use of ignition tubes, self-starters, better thermal efficiency, and larger powers. Electricity followed on, and references made to its various applications, including that for printing the daily and weekly papers when power was only required for short periods per day, saving initial outlay, space, attendants, and firing-up losses. Suggestions were also made that electric light companies should sell current for power purposes at any time of day or night at a reduced charge. Electric, cable, and steam traction were then reviewed, as also the particulars of the systems and costs of working. In conclusion, he gave a few words of advice to the younger members who had elected to follow the profession of an engineer, recommending a sound practical training by day with theoretical study in evenings; to follow up some speciality to the hilt, but at the same time to obtain and maintain a good general knowledge of other branches.

The Finances of the Bradford Central Station. In moving the adoption, on Tuesday, of the accounts referring to the central electric light station during the past half-year, Alderman Moulson gave some interesting figures. He stated that the works were in fairly good order, that the buildings had been completed, the contractors paid off, and the engineer as well. Two engines were ordered last year. One had been doing good service since about the middle of December, and the other would be finished in about a fortnight. The engines were of 200 i.h.p. each. There was still room for other two. During the half-year the sales of electricity came to £5,510 (£4,548 in 1892); hire of meters represented £100 (£79 in 1892). The payments included £1,500 for miscellaneous expenses (£1,204 in 1892); £1,175 for salaries and wages (£793 in 1892); £785 for interest on loans (£719 in 1892); and £827 for sinking fund (£577 in 1892). The total was £4,463, against £3,562 in 1892. The total amount of the capital was £56,679. The total number of lamps connected with the mains, or their equivalent in current, was 28,400. About 2,500 yards of mains had been laid during the six months. There would have been in connection with the electricity works a very good profit had it not been for the coal strike, which had made the coal cost about £600 extra. Alderman F. Priestman, at the close of Alderman Moulson's statement, expressed the opinion that it would be a very great advantage to the committee and the Corporation to reduce the price of electricity to 2½d. or 3d., for motive power only, during the day. He had reason to know that people who were using a considerable amount of current would not go on paying 5d. for it, which was a higher price than they were giving for other motive power.

Lighting at Gothenburg.—The generating station of the Elektron Lighting Company, Limited, at Gothenburg, is on the low-tension three-wire system. The plant consists of two Babcock boilers for a working pressure of 150lb., a fuel economiser, one triple-expansion engine of 300 i.h.p., one of 240 i.h.p., one of 75 i.h.p., and one compound of 75 i.h.p. The dynamos are rope-driven from engine flywheel. The larger ones are of the Crompton type and the smaller by a Swedish maker. The small engines have each their own jet condenser; the large engines exhaust to a common jet condenser worked by direct-acting compound cylinders The boilers work with forced draught, the air being blown into the closed ashpit by an ordinary blast fan worked by separate engine. The cables are all carried overhead on Callender's bitumen system. The lighting embraces 28 1,400-c.p. arc lamps for the harbour illumination, 51 arc lamps for shop-lighting, and some 5,600 16-c.p. and a few 5, 8, 32, and 50 c.p. incandescent lamps for shop and domestic lighting. In addition to these, the station supplies current to some 20 motors ranging from ¼ h.p. up to 8 h.p., aggregating about 45 h.p. The service is constant all the year round. The total output during the past year was 516,117 units. Most of the current being sold by contract and not by meter, an average loss on the cables of 15 volts can be allowed for in order to arrive at the current actually sold. This gives 457,908 units. The total income from the sale of current was £4,544, or 2⅜d. per unit sold. The coal account equalled ⅔d. per unit at dynamo terminals, or $\frac{9}{20}$d. per unit sold. Mr. James G. Calvert, the managing director, states that the consumption of coal amounted to 7lb. per unit sold, and that the net profits for the year, after payment of all interests on loans and all repairs of machinery, were £1,166.

Settlement of the Newport Tender Question.—This matter, which had been referred back to the committee, was decided on Tuesday, when Alderman H. J. Davis brought up the report of the Parliamentary and Improvement Committee, dealing with the question of the electric lighting plant. It was recommended that the original recommendation be adhered to—viz, that the all-round tender of Messrs. John Fowler and Co., Leeds, for the whole installation except the cables, at a sum of £19,797, be accepted, and that the tender of Messrs. Siemens Bros. and Co. for cables, at a sum of £2,896, be accepted. Alderman Davis proposed the adoption of that report and Mr. T. Goldsworthy seconded. As an amendment, Mr. R. Wilkinson moved that the tender of Messrs. John Fowler and Co. be declined; that the tender of the Uskside Company for the supply of engines be accepted, and that Messrs. Crompton and Co. be offered the balance of the contract on the basis of the amount of their original tender, provided they would give Newport firms the offer to make any machinery, pipes, and other work that could be done in the

Digitized by Google

town on equal terms. He presented a petition from the Society of Engineers, Steam Engineers' Society, and Iron-founders' Society in favour of the adoption of the course he had proposed. The amendment was seconded by Mr. T. Cordey. A long discussion then took place, and ultimately the amendment was defeated by 20 votes to 5, there being 10 neutrals. Mr. W. H. Brown then moved as a further amendment that the former amendment of the committee be adhered to, to give the tender to Messrs. John Fowler and Co., except as to cables, which were to be given to Messrs. Siemens and Co., and to engines, which should be given to the Uskside Company, of Newport. Mr. E. Griffiths seconded this amendment, upon which there was also a large amount of discussion. Ultimately it was agreed to by a large majority.

The Municipalisation of Electricity Works.—A fortnight ago, as stated in our issue of the 2nd inst., the London County Council referred back to the Finance Committee an application by the St. Pancras Vestry for a loan of £30,000 on the ground that the total initial cost should be extended over a reasonable period, and without regard to the life of any particular portion of that which forms initial cost. On Tuesday, after reconsideration, the Finance Committee reported that they had again given careful consideration to the application of the Vestry for the loan of £30,000 for 42 years on the annuity system. As stated in their former report, the Council had already sanctioned loans for £10,000 for the purchase of one site, repayable in 50 years, and £8,000 for another site, and £60,000 for works, both repayable in 42 years. The loans for £10,000 and the £8,000 for land were advanced by the Council, and that for £60,000 borrowed elsewhere, as the Council had no power at that time to lend for other purposes than the purchase of land for a longer period than 30 years. This restriction was, however, removed by Section 7 (iv.) of the Money Act of 1892, and the term of 50 years fixed as a maximum limit. On July 26 last they reported on the Vestry's application for a further loan of £30,000, when they recommended (having regard to the amount already borrowed and to certain other circumstances referred to in the report) that the loan should be limited to £15,400. The Council concurred in their recommendation that the repayment of that sum should be spread over 42 years. The Vestry had not taken up this loan, and it now renewed its application for the £30,000. Having regard to questions raised since in connection with a depreciation fund for renewals of plant and machinery, the committee felt it their duty to further consider the whole subject of the term for which loans for electric lighting purposes should be sanctioned. They were sensible that the question was one of great importance to the local authorities of London, and they were anxious that the Council should do what was possible to stimulate municipal enterprise, regard being had to the duty placed upon the Council by statute of controlling the borrowing by vestries and district boards. It must not be forgotten that, as the sanctioning authority for loans to vestries and district boards under the Electric Lighting Acts, the Council was charged by Parliament with the duty of protecting the interests of future ratepayers as well as of doing justice to the necessities of the present ratepayers. After full consideration of all the circumstances of the case, they had determined to recommend that a loan of £29,700 should be sanctioned for a term of 25 years. After some discussion, the report and recommendations were adopted. The County Council agreed to lend the Vestry of Islington £9,000 for 55 years for the purpose of purchasing a site for an electric lighting station.

Telegraphy Between England and India.—The members of the Indian Section of the Society of Arts listened last week in the Imperial Institute to a paper read by Mr. E. O. Walker, C.I.E., late of the Indian Telegraph Department, on "Telegraphic Communication Between England and India; its Present Condition and Future Development." The author first described the gradual growth of the Anglo-Indian telegraph service. He next touched upon the tariffs, traffics, earnings, and profits of the lines, with other kindred details. When communication between England and India was first opened, he said, the unit of charge was a message of 20 words for £5, or at the rate of 5s. per word. At the present time from England to India the rate was 4s. *vid* Suez and Teheran, and 3s. 8d. *vid* Turkey. From India to England the corresponding rates were Rs.3 4a., and Rs.2 15a. It would surprise most to know that the total amount paid for telegrams between India and the United Kingdom in 1891-92—namely, £270,000—was only about ¼ per cent. of the value of the total trade—Rs. 95,222,155. He attributed this unnatural restriction of traffic solely to the high rate which prevailed. The inland telegraph traffic in India in the last 20 years had increased from 684,388 to 3,441,637 messages; while that exchanged between that country and Europe had increased from 50,462 to 193,782 messages by all routes. This number, it must be noted, included all Indo-European official, commercial, Press, and domestic messages. Thus, setting the continental traffic aside, India and England only exchanged about 465 messages per working day. This fact, when compared with the volume of their mutual trade and with the enormous political interests common to both countries, spoke for itself. The question next arose, what amount of traffic could be easily carried by the Indo-European and Eastern Companies with their existing lines should the introduction of a reduced rate largely augment the number of telegrams? There was another feature in modern telegraphy by which, without increasing the capital outlay by more than a small sum—£15,000 in the case of the Eastern Company's cables—the carrying capacity of the circuits was almost doubled. This was the "duplex system," which, by special arrangements of apparatus at the ends of a circuit, but involving no alteration of the wire or cable itself, permitted of messages being transmitted simultaneously from each end. Dr. Muirhead's efficient duplex system, which was applied to the Eastern Company's cables some 12 years ago, about doubled the carrying power of a circuit. It afforded means of now dealing, in conjunction with the Indo-European Company, with over 7,000 messages daily. The charge could, and should, be reduced by 6d. yearly until the present rate—4s.—was lowered to 2s. 6d. What was essential to the introduction of a permanently low charge was the extension of the overland systems of telegraphs. There were three links to be completed in these systems, which would, with a properly organised service under central control in connection with the European lines, certainly afford means to India and England of exchanging correspondence far more cheaply than at present. They were as follows: Shiraz to Jask, in Persia, 575 miles; from Mashad to Herat, and thence to Kandahar and Quetta; and from Merv to Herat, *vid* Penjdeh. It was essential to the success of the working of long lines passing through foreign territories that they should be administered by one responsible directorate, and existing circumstances pointed to the Home and Indian Governments, as well as the company that had already achieved such good results, as the authorities best qualified to promote telegraphic enterprise in the localities he had indicated.

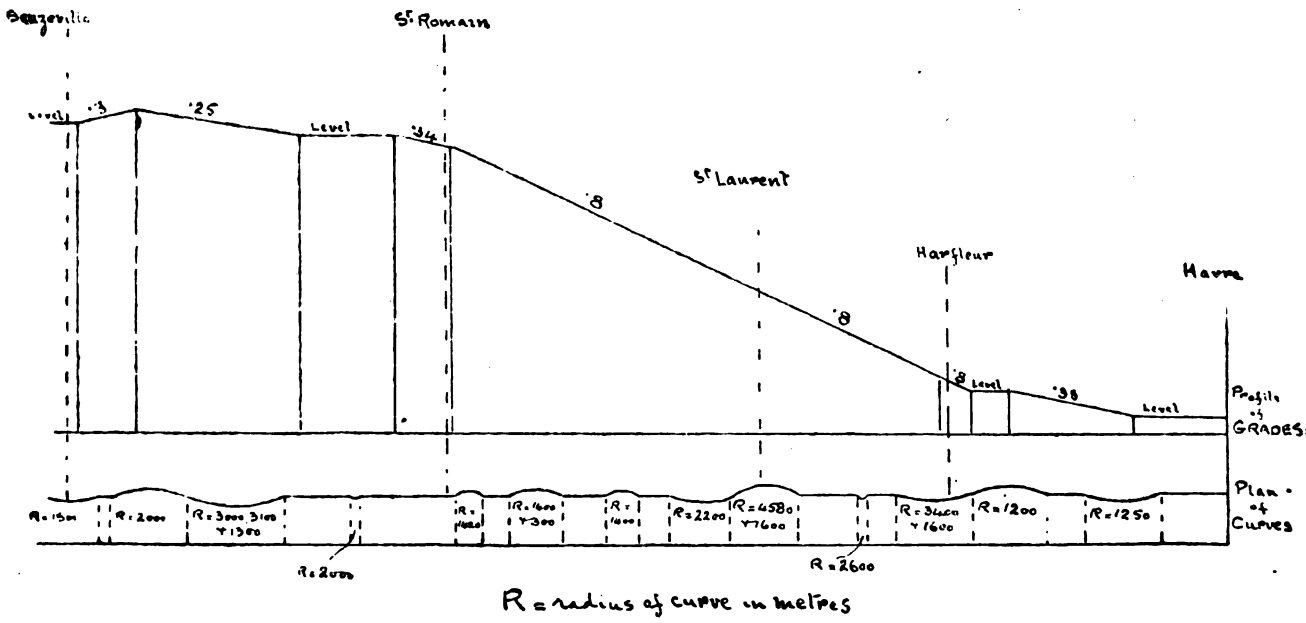
THE HEILMANN ELECTRIC LOCOMOTIVE.

BY FRANK B. LEA.

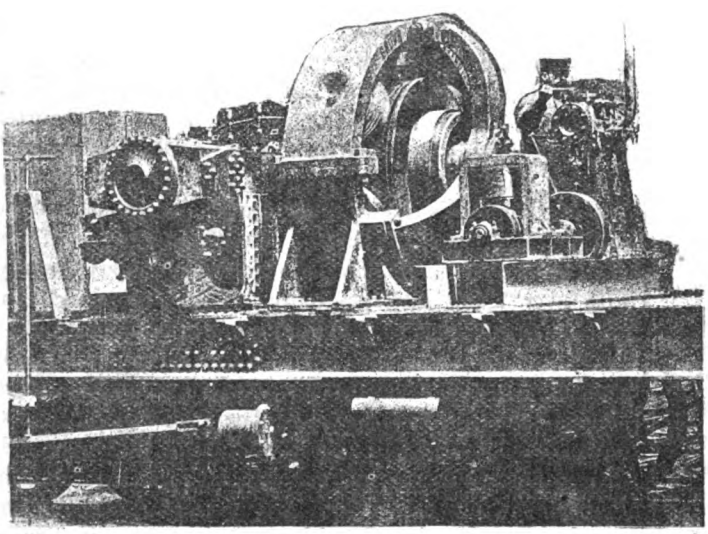
On Saturday last I was enabled, through the courtesy of Mons. J. J. Heilmann, the inventor of the unique contrivance, and managing director of the French company which is developing its use, to join a number of engineers and others interested in the progress of rapid-transit methods in a trial trip of the Heilmann locomotive upon the railway out of Havre towards Paris. Here, along the main lines of the Chemin de Fer de l'Ouest, very successful runs were made between the terminal station at Havre and the village of Beuzeville, about 16 miles distance, this place being chosen as a convenient turning point, so that several trips might be taken in the day. Of course—as will be seen further on—there is no actual limit of the locomotive to any distance so long as coal and water can be obtained.

It seems to be pretty generally admitted that electric locomotives have for such purposes very great advantages over those operated by steam, and the reasons for this are by now so well known and discussed (*e.g.*, the abolition of reciprocating parts—piston rods, side rods, etc., connected to the driving-wheels; the ease with which all wheels may be made drivers, and all the locomotive weight available for adhesion; a lowered centre of gravity; and greater ease in running round curves, due to a shorter rigid wheel base, etc.), that it is hardly necessary even to enumerate them all.

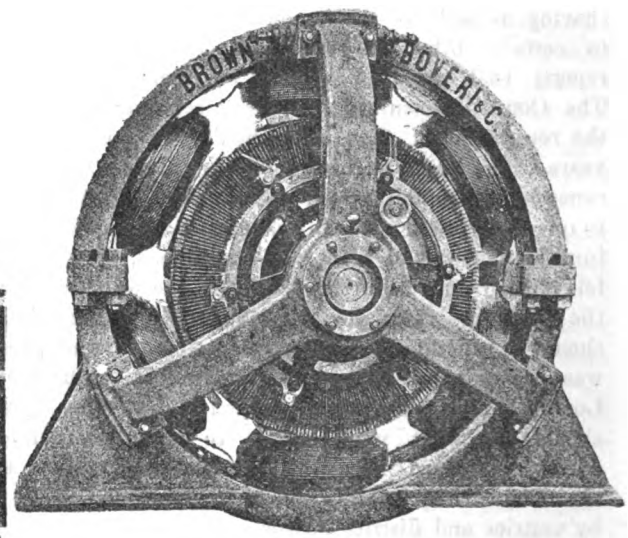


Heilmann Locomotive.—Profile of Line Showing Gradients Per Cent.

The essential feature, however, of the Heilmann design, as opposed to all other electric locomotives, lies in its being wholly "self-contained"; independent, that is, of a generating supply station and line conductors for conveying current, as on the South London and the Liverpool railways. Of course, this very characteristic—the hauling about by each locomotive of its own steam and electric generating plant—appears enough in itself, when first considered, to brand the whole device as being absolutely uneconomical, if not absurd. Why, it is asked, not at once use the steam power for rotating the engine wheels (as in the ordinary locomotive) if a boiler and steam-engine must be carried at all?



Heilmann Locomotive.—View Showing Main Steam Engine, Dynamo Generator, and Exciter.



Heilmann Locomotive.—View of Dynamo Generator.

Details of this locomotive have already been published from time to time in these pages as the work of design and construction proceeded; but this being its first public appearance, a more extended notice ought to be given, summarising its chief characteristics, criticising where necessary the parts not yet fully perfected, and assigning such amount of praise as an unbiassed observer will feel that the device fully deserves.

The main idea of Mons. Heilmann in designing and constructing this locomotive appears to be the provision of better and more suitable means for the attainment of high speeds, perhaps, particularly with light loads—that is, to run at the outset express passenger traffic.

The great additional weight of locomotive, and the extra energy transformation, cannot fail, it has been asserted, to incur a great waste of power and fuel, instead of effecting an economy in it.

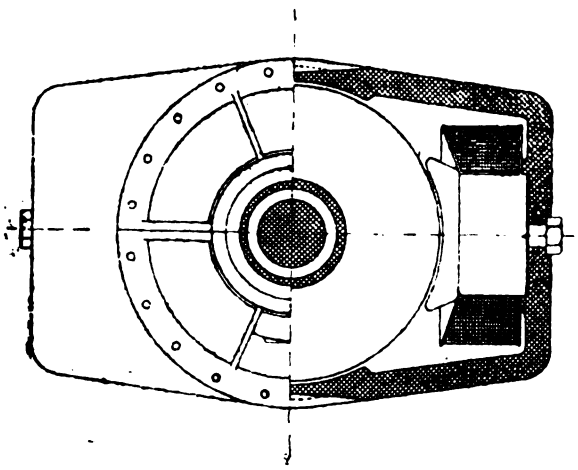
On the other hand, Mons. Heilmann claims—quite rightly—that his method of working enables high-speed electric traction to be adopted at once on any line without interfering with present conditions or necessitating expen-

Digitized by Google

sive changes in the permanent way, or requiring the erection of fixed generating stations whose capacity is practically limited as regards length of line operated, and which at the outset would have extremely small load factors, with consequent lack of efficiency.

The chief difficulty in coming to a decision of any value whatever on the matter lies most in the absence of accurate monetary values which we may assign to increase of train speed and greater safety of travelling. There is no doubt whatever that these latter advantages are worth something to the public who use railways; and if a greater volume of traffic is induced at reasonable rates, a small increase in working expenses might, from the railway manager's point of view, be perfectly justifiable.

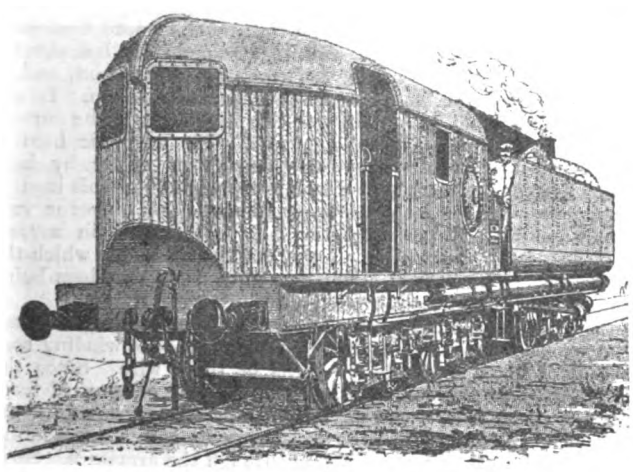
But although I am assuming that the working expenses



Heilmann Locomotive.—Vertical Section through Motor along Truck Axle.

would necessarily be increased on the employment of locomotives after the Heilmann pattern, this is not as yet by any means finally determined; and until the tests just made and carried out by the French railway officials are publicly announced and analysed, it would be unfair to say absolutely that the Heilmann locomotive could never prove economical.

At the present time, moreover, it is practically impossible to persuade any railway company now working a line by steam to change the system so that electric traction shall be wholly, or even partly, employed upon it. The initial



Heilmann Electric Locomotive.—General View.

outlay would prove so great that all interested persons might well shrink from discussing the change, and still more from actually carrying it out.

In April last some details of the locomotive were published in the *Electrical Engineer*, and these, repeated with some illustrations, will show its leading features. The description ran thus: "The boiler and generating machinery are carried on a frame, 53ft. long, which rests on two eight-wheel bogies. On either side of the boiler are coal-bunkers having a total capacity of six tons, and water-tanks for 2,200 gallons. The total power of the locomotive is from 600 h.p. to 800 h.p., and its weight, when in service, 42 tons. The boiler is of the Lenz type; length over all, 26ft.; diameter, 6ft. 4in.; grate surface, 24·5 square feet; heating surface of firebox, 200 square feet; heating surface of tubes, 1,400 square feet. The engine and generating dynamo are carried in front, and a small steam dynamo is used for excitation. The main engine is compound, with the cylinders in line, and crankshaft between them. The cranks are set 180deg. apart, so as to obtain balance between the running parts. The cylinders are 16¾in. and 25⅝in. in diameter, the stroke being 12in. The brake horse-power at 300 revolutions per minute is 600, and at 500 revolutions 800 h.p. Weight of engine, 5 tons 3cwt. The generating dynamo is coupled direct to the engine shaft, and is a six-pole machine with ring armature wound for 400 volts and 1,025 amperes, at 300 revolutions per minute. The diameter of the armature is 49in. Each of the eight axles are provided with a four-pole motor of the iron-clad type; diameter of armature, 25½in.; diameter of driving wheels, 45½in. Maximum speed of motors, 560 revolutions per minute."

The electrical equipment of the locomotive is admirable throughout, as might be expected from the firm (Messrs. Brown, Boveri, and Co., Basle, Switzerland) responsible for it, and no criticism of any part thereof is required. So far as the steam plant is concerned, it seems advisable that some improvements should be effected in the main steam-engine. At present the stroke is far too short for the energy transmitted, and serious knocking with heavy wear would result in practice. Steam-turbines cannot well be employed in the absence of condensing plant if a reasonable efficiency is to be aimed at, but an engine of the Willans or Rigg type might serve the purpose, if the height can be kept down.

The arrangement of boiler adopted is good, and, indeed, except for the main steam-engine, the entire locomotive strikes one as being a thoroughly well-designed and sound piece of engineering.

Of course the conditions of a trial trip are no great criterion of working practice, but it was easy to see, when running last week, that in all essential features the locomotive fulfilled the claims put forward by its inventor, whilst several minor details, to which objection could readily be made, were such as might be remedied with little trouble. When accurate figures can be obtained and published as to the coal and water consumed for a given electrical output or haulage effected, it will be possible to compare the Heilmann locomotive with others operated by electricity in the more usual manner, or by steam.

THE CONSTRUCTION AND WORKING OF ELECTRO-MOTORS.*

BY A. H. DYKES, A.I.E.E.

Engineering now embraces so many departments that it is impossible for any one man, much less any young man, to have an intimate acquaintance with them all. The more branches of his profession he possesses a knowledge of, however, the better engineer will he become. It therefore has always appeared to me that one of the chief aims of the papers read before our society should be not so much to describe minutely or discuss exhaustively the latest improvements in any one branch which can well be left to the older societies representing each separate department, but to give members a practical knowledge of the leading features of subjects lying outside their own special line of work. For instance, an advanced treatise on dynamo design, although an excellent paper perhaps for the Institution of Electrical Engineers, might prove of little value to my friend whose work lies among air-compressing machines, and a paper on the very latest improvements in detail of cold-air plant would certainly prove less useful to myself than a more elementary paper on freezing processes. To me, the great charm of our meetings is when some member whose work lies widely apart from my own is kind enough to start me on the right road towards getting a working knowledge of a subject with which hitherto my acquaintance has been slight. So much by way of apology, if any be needed, for venturing to deal with my subject in as simple a manner as possible. If I am able to-night to help anyone to a clearer understanding of the principle underlying the successful application of electromotors, I shall feel that I have to some slight extent repaid the debt of gratitude I owe to the authors of former papers which I have heard at our meetings or read in our *Transactions*.

* Paper read before the Junior Engineering Society.

We all know that from one pole to the other of any magnet stretch what are called lines of force, invisible to the eye, but capable of showing their presence in various ways, as by the manner in which they cause light iron particles to group themselves in regular lines from pole to pole. Now, if any conducting body through which a current of electricity is passing be placed in this field of force, it will have a tendency to move across the field, cutting the lines of force in its path. If a bar, Fig. 1, is free to roll along the rods, *b b*, in the magnetic field, represented by the arrows, then on sending an electric current through it from the battery, *d*, it will tend to move across the field in a direction at right angles to the current and at right angles to the magnetic field. As long as the friction is greater than the force tending to move the rod, the electrical pressure,

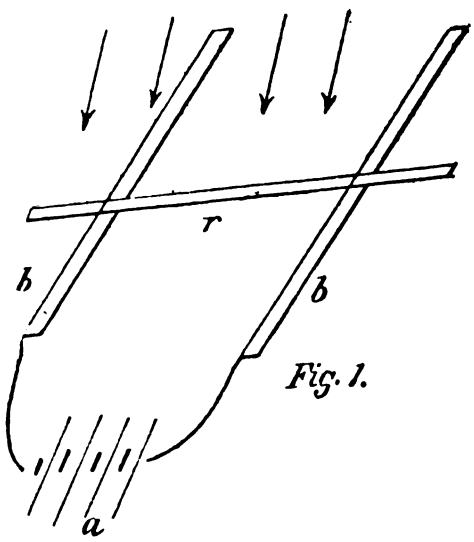

Fig. 1.

or potential, required to drive a given current through the rod will be simply given by the product of the current, *c*, and the electrical resistance, *r*, of the rod—*i.e.*, P.D. $= c\,r$; and the work done $=$ E C, or $c^2 \times r$. When, however, any body cuts lines of force, an E.M.F., or difference of electrical pressure, is set up in it, and therefore directly the electrical force acting on our rod overcomes the friction, and the bar begins to move, the P.D. to drive the current through it $=$ P.D. $= e + c\,r$, where *e* is the E.M.F. set up in the bar due to its cutting the lines. The electrical work done is now $c\,e + c^2\,r$, where $c\,e$ is the equivalent of the mechanical work done in moving the rod against the opposing friction, and $c^2\,r$ the loss in electrical resistance or the internal losses of our elementary motor, and shows itself in heat. From the principle of the conservation of energy, it is clear that if the rod moves against friction or other opposing forces, and thus does mechanical work, we must do work on it, and therefore it is that we get an opposing E.M.F., or back E.M.F., which obliges us to do more electrical work in forcing the current through the bar.

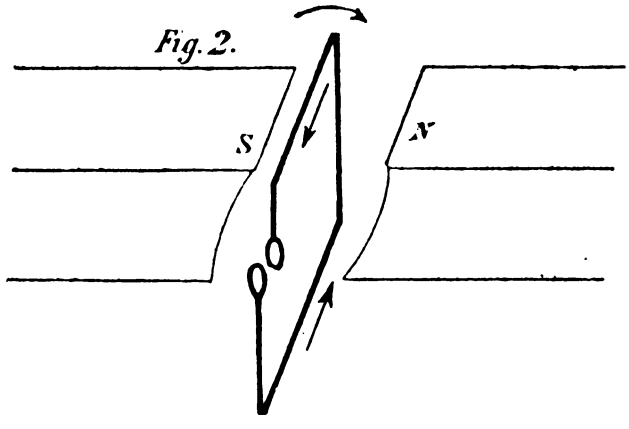

Fig. 2.

All electromotors are simply a combination of these two elements—a magnetic field and a conductor, or conductors, carrying a current. The motion of translation is, however, generally turned into one of rotation, the first step towards which is shown in Fig. 2. Suppose a current be flowing in the direction of the arrow along the top half of the loop, it will try to move it at right angles to the current, and at right angles to the lines of force—*i.e.*, as shown by the curved arrows. The lower half will also tend to move in the same circular direction, and this movement will continue until the coil has moved into the vertical position, when it will stop, this position being a dead point as the motor is at present arranged. If we wind the coil on an iron core, the field will be strengthened, and so the force greatly increased. If, when the coil has made half a revolution, we just help it over the dead centre, and then send the current through it in the opposite direction, it will continue to turn in the field till it completes the revolution. But it can only complete the revolution if the current is reversed after passing the vertical, because in relation to the lines of force each individual half of the coil is moving in the opposite direction during the second half of the revolution to what it was before. We can reverse the current automatically by leading it, not directly to the coil, but by means of brushes to two segments connected one with either end of the coil. This arrangement is called a commutator. The motor, however, will still have a varying torque through the revolution and two dead points. The torque can be made more uniform and the dead centres done away with if we wind a second coil at right angles to the first, so that it is in its best position when the first is on the dead centre, and send the current through both. In practice we put, not two coils only, but many coils, usually 30 at least, and so get a practically uniform torque. The function, then, of the commutator is to reverse the current in the coils as they successively come into the idle parts of the field. There are two principal ways in which moving coils or armatures are wound on the iron core: one by winding right round a drum-shaped core and called a drum armature, and another by winding round a ring, and known as the Gramme winding.

The torque exerted by a motor depends on (*a*) the number of lines of force passing through the armature—*i.e.*, on the strength of the field produced by the field magnets; (*b*) on the current passing through the armature; (*c*) on the number of turns of wire or conductors on the armature. Suppose that a certain armature having a resistance of 0·5 ohm has to give a torque of 100lb.-feet, and that it is so proportioned that it takes 10 amperes to do this. Then, if the volts on the terminals are five, the armature will just give the torque, but will not move P.D. $= c\,r$. If the P.D. on the armature is more than five—say 100 volts—the armature will run faster and faster until the back E.M.F. is 95 volts. Now the E.M.F. set up in any moving conductor is rate of cutting lines, so that if the field be constant the back E.M.F. is speed, and whilst the torque depends on the current, the speed is dependent on the voltage applied to the terminals of the armature, and the horse power of course on the product of the amperes and volts. The torque any motor can give is simply limited by the amount of current that can be sent through the armature. If the motor mentioned above were suddenly called on to give a torque of 1,000lb., it would simply slow up until its back E.M.F. was only 50 volts, thus leaving 50 volts to drive a current of 100 amperes through the resistance of ·5 ohm. If the load on the motor be increased still further, so that it cannot move at all, the current will be $\frac{100}{\cdot 5} = 200$ amperes, or 20 times the normal. The effect of so excessive a current as this would be to overheat the armature winding and probably burn it out.

Where a motor is fitted with a brake for stopping it, it should be arranged that the action of putting on the brake first stops the current. It is also as well to arrange with belt-driving motors that the belt slips if too great a load is put on, and so relieves the motor from an excessive electrical strain. In any case, fuses should be put in the circuit to meet if the current exceeds, say, three times the normal. The magnetic field in which the armature rotates can be produced either by hard steel permanent magnets or by electromagnets of soft iron or steel; the former material is practically used only for very small motors. Electromagnetic fields are excited in several different ways, depending on the conditions under which the motor has to be worked. The two most usual windings being the series and shunt.

In a series-wound motor the current, after passing through the armature, goes round the field magnets—the winding consisting of a comparatively few turns of thick wire. Since the strength of an electromagnet, or the number of lines of force passing through it, varies with the ampere-turns round it, the strength of field in which the armature runs is in a series motor dependent on the current passing through the armature. Now, if the E.M.F. on the terminals of the armature be constant, the weaker the field the faster it must run to generate sufficient back E.M.F. to keep the current down to just that quantity sufficient to do the mechanical work required. It therefore follows that in a constant voltage circuit the speed of a series motor varies inversely as the current taken by the armature. To take an instance. The motors used on the City and South London Railway take normally a current of about 65 amperes, and run at 222 revolutions per minute, 17·8 miles per hour. The pull they then give on drawbar of the train is 447lb. each. When the torque is increased to 1,642, the current is 163, and the speed 125 revolutions per minute. It will be noticed that increasing the current from 65 to 163, increases the pull to 1,121, and the increase in the strength of the field due to the increased ampere-turns brings the total torque up to 1,642. On the other hand, when the current is only 47, the pull is 298 and the speed 230 revolu-

Digitized by Google

tions per minute. A series motor, then, possesses the advantage that at starting it is able to exert a large torque because its field is then at its maximum strength, but it is absolutely no use where constant speed under varying load is required. It is extremely well suited for electric tramways and railways where at low speed, when starting a great pull is required, which gets less when the train is well under way. The usual plan is to have in series with the motor a starting resistance, which is cut out at such a rate that the starting current is about two and a half to three times the regular working one. As the inertia of the train is overcome the current drops, and the speed therefore increases until it attains the normal. After this any increase is obtained by weakening the field, either by cutting out some of the series coils or, better, by shunting part of the current round them. The only limit to the speed that can be obtained by these means is when the current in the armature becomes too great, or the sparking owing to the weak field too excessive.

In a shunt motor the field-magnet winding is in parallel with the armature, and consists of a comparatively large number of turns of fine wire, through which only a small fraction of the main current passes. If used on constant-potential leads, the excitation of the magnets is constant, and quite independent of the armature current, and therefore if it were not for the drop in volts due to the resistance of the armature, the speed would be constant; e (the back E.M.F.) $= E - c\,r$, so that if r is appreciable the back E.M.F. is reduced, and therefore the speed decreases with the current. This is, however, somewhat counterbalanced by the increased current in the armature demagnetising the field, and therefore requiring a higher speed to give the same back E.M.F. For all practical purposes, a shunt-wound motor, well designed, and having an armature of not excessive resistance, gives constant speed with constant P.D. on its terminals. Before switching current on to the armature of a shunt motor the field circuit must be closed and the magnets excited, otherwise, the armature offering, when at rest, little resistance, an excessive current will pass through it, and practically move round the fields, and the motor will not start. The shunt switch should be combined with the starting switch, so that the main current cannot be switched on until the magnets are first excited, nor the shunt circuit broken until the armature circuit is disconnected.

With both series and shunt motors, a starting resistance should be put in series with the armature at starting and gradually cut out as the speed, and, therefore, the back E.M.F., increases. The reason for this is, that just when starting, the back E.M.F. is nought, and therefore switching on full volts would send an extremely large current through the armature, causing a sudden jerk on the gearing and on the armature conductors, and also heating the winding. If the motor be running off a lighting circuit, too, such a sudden rush of current would cause the lights on the same mains to flicker. Most supply companies, therefore, stipulate that the resistance is to be such, and divided up into so many steps, that the current shall not at any step be increased by more than 10 amperes. Constant-current motors are little used in England. In America, where constant current as lighting circuits are so popular, they are better known, series motors being often run thus. The speed is regulated or kept constant by cutting out some of the field coils when less torque is required, and putting all of them in series when the maximum pull has to be given. To sum up. Where constant speed with varying load is required, shunt motors on constant-potential circuits (as lighting circuits) should be used; but where the work is constant, or where a large torque at starting, diminishing as the speed increases, is wanted, series-wound motors are most suitable. We therefore find shunt motors driving workshops, machines, etc., and series motors on electric locomotives, trams, and boats, and also driving fans and centrifugal machines. For electric drills series motors have also been used, as they automatically slow down when taking a heavy cut with a large drill, and speed up when drilling a smaller hole. Other things being equal, a series motor is cheaper to make than a shunt, as the field coil, being only comparatively a few turns of wire, takes less time to wind than a shunt coil consisting of a large number of turns of fine wire.

The efficiency of a moter of given size depends on the speed at which it runs—the higher the speed the greater the efficiency. For example, take the case of a motor giving 10 brake horse-power at 500 revolutions, and absorbing 100 volts and 88 amperes; 10 h.p. is equivalent to 7,460 watts, whilst the watts absorbed are $88 \times 100 = 8{,}800$, leaving 1,340 watts wasted in heat inside the motor itself, or an efficiency of 84·8 per cent. If we supply it with current at 200 volts, so that it runs at just over double the speed, the power wasted inside will remain the same, and the output will be $(200 \times 88 = 17{,}600) - 1{,}340 = 16{,}260$, giving an efficiency of $\frac{16{,}260}{17{,}600} = 92{\cdot}4$ per cent.

High-voltage motors are usually much less efficient than those wound for lower pressure, as there is a great deal of space taken up by insulation which gives less room for copper. A large 300-h.p. motor wound for 250 volts, at a speed of 350 revolutions, had a commercial efficiency—*i.e.*, $\frac{\text{mechanical power given out}}{\text{electrical power absorbed}}$, of 96 per cent. The City and South London Railway motors gave an efficiency of 94 per cent. at 222 revolutions. A 220-volt motor giving 3½ brake horse-power at 394 revolutions gave 70 per cent., whilst at 1,600 revolutions a 1½-h.p. 100-volt motor gave 75 per cent. When specifying the efficiency of a motor, then, these considerations must be taken into account, as what may be a low efficiency under one set of conditions may be a high one under another. First, the higher the speed the greater the efficiency; secondly, the higher the output the higher the efficiency; thirdly, usually the lower the volts the higher the efficiency.

We have seen above that the function of the commutator is to reverse the direction of the current in each armature bar or winding, as it gets into the neutral part of the field. When the motor is running light, and scarcely any current passing through the armature, the main field runs straight across from pole to pole. The effect of the currents circulating round the armature is to magnetise it in a direction at right angles to the main field, the magnetisation increasing with the current. This causes a resultant field inclined to the main field, and necessitates the line of the brushes (which has to be approximately at right angles to the field) being shifted backwards, or, as it is called, "having a back lead," by an amount increasing with the current. (If the brushes are not shifted backwards excessive sparking will result, causing great wear of the brushes and commutator.) Obviously this lead can be made very small by making the main field very powerful comparing with that due to the armature. In tramway motors and others that have to be put into inaccessible places, where the brushes cannot be shifted as the load varies, it is of the utmost importance that the armature field be very weak.

When selecting a motor to do certain work, the torque, or effort, it has to give at starting should be borne in mind, as well as simply the horse-power it must give when running; and if it is to be started and stopped very often, it pays well to put in an amply large motor. It is, unfortunately, only too easy to put a sudden excessive strain on the armature when starting by switching out the starting resistance too suddenly. Many pieces of apparatus, such as centrifugal machines, take a very large torque to start them, but little power to keep them running when once they have been started. All motors should have at least two brushes on each side of the commutator, or four in all, so that in the event of one pair being disabled, the current can still flow through the other. Great care must be taken to keep all parts of the machine clean, especially the commutator. Oil and dirt on the latter is responsible for many a failure. No part of the magnets or armature should be allowed to get too hot, a temperature of 200deg. F. being about the limit for safe continuous working. For short runs, the normal output of the motor can be considerably exceeded, provided that at no time does the temperature rise higher than the figure given, and that the commutator be not injured by sparking.

The faults most likely to occur are two—"earths" and "shorts," the former being when any part of the winding or commutator makes contact with the frame or earth, and the latter, when two parts of the winding, supposed to be insulated from each other, come into contact. The final result in both cases is usually the same—an excessive local current flows and burns out the injured part. The "earth" can be detected by connecting either terminal of the machine in turn to one end of a piece of wire and striking the other end of the wire on to the spindle or frame. If there is any earth there will be a flash or spark when the wire touches the frame. A "short" can be found by running the armature in its fully excited field and holding near to it a key or other light piece of iron. If the winding is sound a steady pull will be felt on the key, but in the event of a "short" there will be a jerk or tug on the key whenever the bad place on the armature comes opposite it. If run long enough the fault will also show itself by local heating of the damaged coils. It also often happens that the wires connecting the commutator parts with the winding break, a fault to which tramway motors which run in both directions and have to endure a lot of vibration are particularly liable. If, however, care be taken to handle the armatures gently, to prevent the insulation getting scratched or knocked, and to keep the whole machine clean and dry, motors give very little trouble, and require no skilled attendance. They are safe, clean, and noiseless, and can be started and stopped with the utmost ease, and thus can be put into a situation where any other form of motive power would be out of the question.

The Electro-Harmonic Society.—A ladies' night of this society will take place in the Banquet-room of the St James's Hall Restaurant, Regent-street, W., on Friday next, the 23rd inst, commencing at 8 o'clock. The programme, although short, should prove interesting. The artistes include Miss Beatrice S. Lucas, Miss Rose Dafforne, Mr. T. H. Harrison, and Mr. Holroyd Smith. The musical directors are Messrs. T. E. Gatehouse and A. E. Izard.

ST. PANCRAS ELECTRIC LIGHTING INSTALLATION.*

BY PROF. HENRY ROBINSON, M.I.C.E., M I.E.E.

I have pleasure in complying with the request that I should describe at the Society of Arts the electric light installation that I have carried out for the St. Pancras Vestry. I would state at the outset that St. Pancras was the first municipal authority to appreciate the importance of preserving the business of electricity supply in its own hands, inasmuch as in the year 1882 the vestry clerk, Mr. T. Eccleston Gibb (to whom is mainly due the successful action of the Vestry throughout), called the attention of the Vestry to schemes which had for their object the acquisition of electric lighting powers in the St. Pancras parish. In a report of his in that year he says: "A few years ago it was generally believed that electric lighting would not be made available for private houses and buildings for many years, although it might shortly be brought into use for public lighting. The invention of the incandescent lamp and other improvements have revolutionised the question of electric lighting, and while public authorities are in many cases giving up their experiments in street-lighting, the several companies are extending their systems to buildings of all descriptions, and the time seems to have gone by when there is a willingness to undertake costly experiments in public lighting. It is probable now that the electric lighting will be adopted in private buildings before the local authorities adopt its use for street-lighting, and, therefore, the acquisition of the powers of monopolists are more likely to pass unnoticed by the local authorities, and thus control over streets, etc., obtained similar to that exercised by water companies."

In connection with the views thus expressed by Mr. Gibb, as far back as 1882, I would quote the following from the inaugural address of the President of the Institution of Electrical Engineers in January last: "The financial success which has invariably attended the municipal electric enterprises has relieved the rates at the expense of the wealthier classes in a perfectly legitimate manner; and the more electricity becomes one of the common necessaries of life, the better it is that the supply should be in the hands of the community, and not in those of monopolists. A strange fact in connection with this subject is that the great majority of the local authorities should have waited until the passing of the Electric Lighting Act, 1889, before applying for powers to supply electricity, for it must not be forgotten that their position was in no way affected by the alteration of the Electric Lighting Act, 1882. The explanation must, perhaps, be looked for in the exaggerated expectations that were raised by the statements of company promoters in the year 1882, when the most reckless assertions were made as to the results to be obtained by establishing electric systems of distribution The natural consequence was that the enquiries set on foot by various local authorities in no way confirmed the sanguine estimates that had been dangled before the public to obtain its support; and the total failure of the electric light companies to carry out a single one of the orders and licenses obtained by them in the year 1883 and 1884, made the local authorities hesitate before they embarked the ratepayers' money in such precarious undertakings. Fortunately for the progress of our industry, there were some corporations who could be convinced by the result of their enquiries that the use of electric light would be very advantageous for a variety of purposes, and that the knowledge and ability of the electrical engineers had progressed sufficiently to make a profitable distribution of electricity from a generating centre possible. We have seen that their example has been largely followed, and there is every prospect of a continuous and ever-increasing development of this branch of electrical engineering."

On the passing of the Electric Lighting Act, 1882, I, in conjunction with Dr. Hopkinson, F.R.S., advised the Vestry to obtain a provisional order, and it was obtained in 1883. Owing chiefly to financial and other difficulties in connection with the electric lighting companies, as before mentioned, public confidence was shaken, and the order remained in abeyance. In 1888 various companies made applications for provisional orders, by which the Metropolis was proposed to be divided amongst them, but at the Board of Trade enquiry that was held in 1889 the St. Pancras Vestry succeeded in getting their district excluded from the operation of any company. I was thereupon instructed to prepare a scheme to serve in the first instance the south-west, or Regent's Park, division of the district, which formed the compulsory area under the order. In advising upon this, I kept in view the ultimate requirements of the other parts of the St. Pancras district, so that the first installation should form part of a comprehensive scheme. I decided upon adopting the continuous-current system.†

The situation of the site that was originally proposed by the Vestry necessitated the employment of high tension with five transformer sub-stations to feed a network of low-tension distributing mains. The ultimate acquisition by the Vestry of a more central site in Stanhope-street (consisting of 21,000 square feet of freehold property, purchased for £10,000) enabled me to adopt the low-tension direct-supply system entirely for private lighting, and to have only one battery sub-station at the Cobden Statue, 1,140 yards from the central station. It was decided to work the public arc lamps by high-tension continuous current independently of the private lamps. The plant was designed at the outset to serve 10,000 incandescent lamps of 16 c.p. simultaneously in use, and 90 arc lamps of 10 amperes each for public lighting. I should mention that the action taken by the Vestry was not adopted without strong opposition being offered (which is, in fact, still continued) to the Vestry's undertaking this work. However, on January 1, 1890, authority was given by a large majority for the work to proceed. Having overcome opposition from within, a quite unexpected difficulty arose in consequence of uninvited advice and proposals being made from outside (not altogether of a disinterested character) which disturbed the minds of the Vestry. On my advice Dr. Hopkinson and Mr. Preece were consulted, and it was a satisfaction to me that they entirely concurred in my proposals, and the execution of the works, which had thus been interrupted, was proceeded with.

The following is a description of the works: The buildings consist of an engine-house 106ft. by 26ft., a boiler-house 53ft. by 35ft., coal-store 43ft. by 11ft., battery-room 40ft. by 14ft. 6in., testing-room, office, stores, underground tank for condenser water containing 170,000 gallons, chimney 5ft. square inside and 90ft. high. There are 11 engines and dynamos, which are erected on a concrete foundation surrounded by sand to prevent vibration being communicated to the walls, and the floor is carried, independently of the engine foundation, by cantilevers from the walls. The engines are of the Willans type, and the dynamos are of the six-pole Kapp type (made by Messrs. Johnson and Phillips). Nine of these are wound for an output of 680 amperes at pressure varying from 112 to 130 volts. Three are capable of giving 145 volts with a small current for charging batteries at the sub-station, and can be worked self-exciting as simple shunt machines, or separately excited. They were tested with a load of 680 amperes at 118 volts, and the steam consumption was found to be 18·65lb. per electrical horse-power per hour, working condensing, and with the dynamo separately excited. The remaining two dynamos are wound for an output of 90 amperes at from 540 to 575 volts. They are separately excited at low tension, and are used for working 86 arc lamps in the streets, as well as for charging in series four sets of storage batteries of 60 cells each at the central station, which are capable of discharging 60 to 75 amperes. The trials of these two engines showed a consumption of 19·6lb. of steam per electrical horse-power per hour. There are five Babcock and Wilcox boilers, each being 23ft. long and 5ft. wide between the walls, with one steam-drum 3ft. 6in. in diameter. Each boiler has a heating surface of 1,619 square feet and a grate area of 30 square feet, and is capable of evaporating over 5,000lb. of water per hour, the working pressure being 170lb. per square inch. There are two 6in. steam-mains along the top of the boilers fed by separate outlets from each boiler, and delivering into a 6in. main (which extends the whole length of the engine-house) at three points. The mains are so arranged that only two engines are put out of use by the removal of any one pipe. The long pipes are made of wrought iron, the short pipes and T-pieces of cast iron, and the bends of copper. The main exhaust-pipe, under the engine-house floor, varies from 5in. to 15in. in diameter. The steam can be exhausted to the atmosphere, but under ordinary circumstances it passes into a jet condenser, which draws its water from the bottom of the underground tank. Two air-pumps, driven by a Willans compound engine, discharge the hot water from the condenser into the top of the tank. A Körting ejector condenser is provided as a stand-by for heavy loads. From the top of the tank the hot water is pumped by independent circulating pumps to a cooling apparatus, which is capable of dealing with a minimum of 10,000 gallons per hour. The cooling arrangements consist of a large surface of corrugated iron sheets, attached to framing placed round the chimney shaft, the water, after flowing over the corrugated surface, being collected beneath and returned to the bottom of the tank. A dry-air machine is provided for the purpose of delivering dry air into the street-main culverts at the rate of 5,000 cubic feet of air per hour. The air has its due point lowered to 40deg. F.

The arc lamp-posts (86 in number, displacing 479 gas lamps) are of the Brockie-Pell type, and are placed in the centre of the road where this is admissible. In some places, however, they had to be placed on the pavements, as tramways prevented them from being in the middle of the roads. The first lamps that were erected (in Tottenham Court-road and Euston-road) are 25ft. from the ground to the centre of the globe, but those more recently put up, which are chiefly on the pavements, are 22ft. They are fixed at distances varying from 160ft. to 245ft. apart, and are fed with a current of 10 amperes. Eleven lamps are worked in series near the central station, and 10 in series at a distance. Nine arc lamps have more recently been put up in Park-street and supplied with current off the low-tension mains. The main switchboard is arranged on the three-wire system. Each dynamo is provided with a double-pole switch and copper coupling straps to connect the machine to the third wire and to different bars on the feeder-board on either side of the circuit. There is an amperemeter on each dynamo. One terminal of the dynamo switch is coupled by a strap to the third-wire main, and the other terminal is coupled to a bar on the feeder-board. There are four positive bars and four negative bars, and at full load one machine can be run on to each bar and worked at any pressure which may be necessary to serve the feeders which are switched on to it. Thus the dynamos may all be worked at different pressures to suit the demand in the districts which they serve. There are seven feeders, in addition to a direct supply on to the distributing mains, which are connected in a network throughout the district. The bars on the board may be connected directly in parallel or through resistance cells, which will each carry currents up to 180 amperes, offering a counter E.M.F. of from 2 to 2½ volts. By using these cells, current can be supplied to the feeders at four or five different

* Paper read before the Society of Arts on February 14.

† Some data in regard to the various systems of distributing electrical energy I have recently had printed in pamphlet form, and they can be obtained of Messrs. Spon.

Digitized by Google

pressures from one dynamo, which enables the dynamos connected to long feeders to help those serving short feeders, and further enables regulation over large areas when only one dynamo is at work on each side of the circuit. There is an underground sub-station beneath the open space at the Cobden Statue, High-street, Camden Town, at a distance of 1,140 yards from the central station which contains two batteries of 58 cells each. The mains are laid throughout on the "three-wire system," the arterial mains being sufficient to supply 25,000 lamps of 16 c.p. in use simultaneously. The conductors are chiefly composed of bare copper strip 1¼in. wide and ⅛in. thick, supported on edge in glazed porcelain insulators, which are carried on small cast-iron brackets built into the walls of the culverts. Some of the mains are cables laid in cast-iron pipes, and in the extensions now being carried out they are Siemens armoured cables.

The works originally authorised I estimated would cost about £50,000, and this estimate was increased to about £52,000 when the Stanhope-street site was adopted. The actual cost of the works when completed was about £56,000, or within 8 per cent. of the estimate, which, I think it will be admitted, was satisfactory. During the execution of the works originally authorised by the Vestry, extensions were made by the Vestry which involved a considerable increase in the capital expenditure. The works were so far completed as to enable public supply to be commenced on November 9, 1891 (or a year after laying the first stone). By the end of January, 1892, there were 6,500 incandescent lamps of 16 c.p. installed (or their equivalent), and at the end of 1892 there were 11,733, and at the end of 1893 there were 14,617 lamps installed, and many more contracted for, to come on shortly. The current for ordinary supply is charged at 6d. per unit, but it is charged at only 3d. per unit for what is termed "day load," but what might be defined as current supplied for motive power and other purposes at times other than those of maximum demand. The public lighting is at present charged for at the rate of 6d. per unit, which covers the entire cost of production as well as for carbons, trimming, etc., together with all capital charges and maintenance, including lamp columns, lamps, street refuges, etc. The electricity department takes charge of all these matters, and the public lighting account is only debited with one item, "current used," at 6d. per unit. The cost of carbons and trimming for the 95 public arc lights in 1893 was about £600.

CAPITAL EXPENDITURE TO DEC. 31, 1892.

	£	s.	d.
Lands (part only utilised)	10,827	0	0
Buildings	7,653	17	1
Machinery and plant	24,378	17	8
Batteries at central station and sub-station at Cobden Statue	2,961	6	11
Mains, of which some are capable of carrying current for 25,000 lamps	33,787	15	3
Public lamps	6,723	8	4
Meters	1,556	3	9
Electrical instruments, etc.	284	16	3
Office and other furniture and fittings	186	7	4
Preliminary expenses	554	4	7
Total expenditure to December 31, 1892	£88,913	17	2

During the year 1893 a sum of about £10,000 was expended in extensions of lighting, together with mains, meters, house connections, etc. A further increase of the generating plant at the central station has been rendered necessary, owing to the increasing demand for current. These works are now nearly completed, and consist of an extension of the central-station buildings to receive three more engines and dynamos, three additional boilers, together with a second sub-station in Fitzroy-road, near Primrose Hill, 2,700 yards from the central station, containing two sets of batteries. These extensions will cost about £13,000. The "fixed charges" in the shape of the permanent staff, etc., commenced in the middle of 1891, before the public supply of current began. Some of the working expenses of the station during that year, and also in 1892, were incidental to a new undertaking. The following figures for those years, therefore, do not admit of being taken as any criterion of what the normal relation between receipts and expenses will be, but they are given as a matter of record. From the commencement of public supply in November, 1891, to December 31, 1892, there were 11,733 lamps of 16 c.p., or their equivalent current, installed (including 11 motors = 36 h.p., and 92 private arc lamps), of which 6,823 were in simultaneous use. The number of units sold to the end of 1892 was 433,519. The amount charged for lighting the 86 public arc lamps (which were at work only part of the year) was £2,040, the current being charged at 6d. per unit. The total working expenses of all kinds from the commencement to the end of 1892 were £7,438. A sum of £408 was expended on the maintenance of plant. A capital sum of £4,119 was repaid, made up of £400 capital and £3,719 for interest on loans at 3½ per cent. The number of tons of coal used to the end of 1892 was 2,728, and its cost was £2,828, the price of coal being from 20s. to 21s. 6d. per ton. For the year 1893 the following are the figures:

Number of 16-c.p. lamps installed, or equivalent current, including 19 motors = 61 h.p. and 110 private arcs	14,617
Number of 16-c.p. lamps, or equivalent current, simultaneously in use	6,187
Number of units sold for private lighting	397,217
Number of units sold for public lighting	197 676
Total number of units sold	594,893
Receipts for private lighting	£9,546
Receipts for 93 public arc lamps, the current being charged at 6d. per unit	£4,941
Total receipts for current	£14,487
Working expenses	£7,033
Repayment of capital £1,628; Interest on capital, at 3½ per cent. £2,797	£4,425
Expended on maintenance	£1,402
Total for working expenses, repayment of capital, and maintenance	£12,860
Number of tons of coal used	3,180
Cost of coal (price about 17s. 9d. per ton)	£3,006
Cost of coal per unit sold*	1·21d.
Cost of a unit sold if capital had not been repaid	3·4d.
Cost of a unit sold with capital repaid, and maintenance	5·18d.

* This was more than it should have been.

The year 1893 was exceptionally free from fogs, and those which occurred were, I believe, chiefly on Sundays. This led to the receipts for current per lamp installed for that year being below what may be expected over an average number of years. In considering the foregoing table, it should be remembered that the capital repaid is in respect of the cost of a site, the cost of mains, permanent charges, etc., for the supply of a far greater number of lights than those which were supplied during the year, so that, in future years, the cost of production will diminish, inasmuch as the fixed charges and repayment of capital will be spread over a much larger output.

The question of the terms of repayment of the capital for electric lighting by municipal authorities is now receiving serious consideration, as affecting the price at which the public can be supplied with current. The matter has been dealt with by Mr. Gibb, and I refer to the views that he has lately brought before the London County Council, as I am of opinion they have an important bearing on the municipalisation of electric lighting. It has been sought to make the period for repayment of the loans dependent on the life of the machine or apparatus to which it applies, instead of for 42 years. A limit of 42 years was adopted by Parliament, instead of 21 years fixed upon in 1882, as it was found that the shorter period did not enable companies to recoup themselves for their outlay on the monopoly granted them. As it now stands, the ratepayers can only acquire the electric lighting undertakings of companies at the end of 42 years by purchase at their then value; whereas, if an authority extinguishes its capital in 42 years, the future ratepayers succeed to the undertaking without any payment whatever. The view the St. Pancras Vestry take is that the repayment of capital should be spread over a period of 42 years, and that renewals should be met out of profits, supplemented, if need be, by a rate or loan, when the extent of the expenditure justifies it being spread over several rates, by which the present generation of ratepayers would be able to have the benefit of cheap electricity, which it could not otherwise have.

It is often stated that the cost of public lighting by electricity is greater than by gas. If the same standard of illumination had to be obtained by gas as by electricity the statement would not hold good. It is entirely a question of whether or no the standard of lighting does not require to be raised. I think it does. The present lighting of the thoroughfares in the Metropolis is a

Digitized by Google

reproach, and St. Pancras has led the way in reforming this. I am confident that at no distant date the present inefficient lighting of the streets will be looked back upon as comparable with the old oil lamps for which gas was substituted at a great increase in the cost of public lighting. Electricity economically produced by an authority will be available for the "masses," and not only for the "classes," as is often thought. Those who live in small rooms will be benefited, as well as those who live in large, as purity of air and freedom from dirt will result in better health, less work in cleaning, and no injury to decorations. The convenience arising from the employment of electrical energy for working motors is being more and more appreciated, and its uses are gradually extending. A leading London paper is now advertised as being printed by electricity. Where economical power is available, it opens out a wide field for encouraging the establishment of industries where small motors are required to be worked intermittently.

From a social as well as from an economic point of view a municipal authority may regard this part of the electric lighting business as another justification for their undertaking it, especially where large populations are concentrated on a limited area. Simple labour-saving appliances which involve no difficulties in working, and which do not lead to the vitiation of the air, are certain to be more and more relied on as a means of enabling some industries to be carried on in the houses of the workers instead of at factories where the motive power is concentrated. The destruction of town refuse is now recognised as about the best way of getting rid of it, both from a sanitary and financial point of view. The heat produced by the combustion of the refuse can be advantageously utilised for various purposes, amongst others for generating steam. This has led to the combination of a refuse destructor and electric lighting station where the heat produced during the time of working the destructors can be applied to do the work of light loads or in aid of steam boilers. I am now, in conjunction with Mr. William N. Blair, the engineer of the St. Pancras Vestry, carrying out a combined destructor and electric lighting station at King's-road to serve other parts of the district, the outlay on which will be about £40,000 without distributing mains, which will connect it with the existing network, and will enable the heat produced during the daytime to be utilised to do the work of charging the batteries and the light load over the whole district.

Having described the satisfactory results that have already been accomplished, I am confident that it only requires ordinary good administration for a still further degree of success to be attained, which will enable the Vestry either to lower its rate of charge below 6d. per unit, or to have a handsome amount each year to devote to the benefit of the ratepayers. I desire to record my thanks to the members of my staff, and especially to my chief assistant, Mr. Thrupp, for their aid in carrying out these works. In conclusion, I think the St. Pancras Vestry may be congratulated on the success that has attended their enterprise, which has fairly realised the anticipations and calculations upon which it was promoted.

THE RECENT ACCIDENT AT BOURNEMOUTH.

BOARD OF TRADE REPORT.

The following report has been presented to the Board of Trade by Major P. Cardew:

I have the honour to report, for the information of the Board of Trade, that in compliance with the instructions contained in your minute of the 8th inst., I have investigated the circumstances connected with the sudden death of a horse at Bournemouth, under conditions which suggested that the cause of death was an electric shock, due to some defect in the mains of the electric lighting company. The following account of what took place I have collected from the narratives of eye-witnesses:

Between 2.30 and 3 p.m., on the afternoon of the 8th inst., a station omnibus drew up in the roadway opposite to the entrance to the Imperial Hotel in Meyrick-road, Bournemouth. As the horses drew up both suddenly fell down. The driver, William Dean, states that he is certain that the horses did not slip, although there was some melting ice and snow on the road at the time. The driver got down to attend to the horses, and he was assisted by the following men: John King, flydriver; W. Brown, flydriver; T. Binden, carpenter. All these men as well as the driver state positively that when they touched the horses they experienced tingling sensations in their arms and legs, which they attributed to slight electric shock. None of them, however, appear to have been injured by the shock, but the driver's foot was hurt by one of the horses treading on it. One horse was extricated and set on his legs, which appeared to be partially paralysed at the time; the other could not rise and died in a few minutes.

On arrival at the spot about noon on the following day, accompanied by the borough engineer and the superintending engineer of the Bournemouth and District Electric Supply Company, Limited, I had the ground opened at the place where the horses fell, and the iron cover of a street box, measuring 2ft. 6in. by 1ft. 6in., was disclosed about 9in. beneath the surface of the road. On lifting this cover it was found to rest on a brick chamber about 1ft. deep, to one end of which was connected a 3in. iron pipe and to one side a 1½in. iron pipe. The larger iron pipe contained two insulated cables, technically described as 7/20 tinned copper wires insulated with high-quality vulcanised rubber to $\frac{1}{16}$in. thickness and protected by braided hemp. The ends of these cables projected to about the centre of the box, and were sealed up with indiarubber tape and composition. Near these ends two smaller cables of 7/21 tinned copper wires, insulated with similar material, but only to barely $\frac{1}{20}$in. in thickness, and with braided hemp outside, were joined to the larger ones and passed into the smaller pipe. The larger cables had been connected to the supply mains through fuses, contained in a large subterranean chamber at the crossing of main roads, known as the "Lansdowne," about 70 yards away. This connection had, however, before my visit, been severed by cutting the cables in the chamber. The smaller cables merely completed the connection to the transformers placed in the area of the hotel, and were 34ft. in length, and the enclosing pipe was laid at a depth of about 18in. below the surface throughout. All the cables mentioned were used for the high-pressure supply of 2,000 volts. There were no signs of any arcing or injury to the cables or to the lid of the street box, the under surface of which was 5½in. above the cables, but I noticed that one of the "dead ends" beyond the joint to the small cable was covered on the outside with a slimy moisture, and I had this end cut off for further test. On testing it subsequently in water with 2,000 volts alternating pressure, however, no fault was developed.

In order to thoroughly examine the cables and the street box, it was necessary to move the former slightly, but they were disturbed as little as possible, and a test was then made of the insulation of both larger and smaller cables together, up to the point where the connection to the mains had been severed at the large chamber. This test, made with about 100 volts from a small hand-machine, gave an insulation resistance of between four and five megohms from the small pipe—a result which did not indicate any serious leak, considering that the cut ends of the cables had not been sealed up, and some leakage from them was to be expected. On consideration of the matter, however, it occurred to me that possibly the slight movement to which the cables had been subjected had sufficed to move a small defect in the insulation away from contact with the pipe, or that the fault might be such as to give high insulation with 100 volts, but to break down when the pressure was increased to 2,000 volts, so that the fault would not be discovered by the electric test I had made. I therefore requested the electric light company to send for my examination the whole of the cables mentioned so soon as they had withdrawn them from the pipes. This was done, and a distinct defect of insulation was discovered in one of the smaller cables, with evident signs of sparking and some burning of the insulating material having taken place. I do not think, however, from the appearances, that the whole leakage current could have much exceeded one ampere.

Judging from the results of my investigation, and from the attached copy of the report of the borough veterinary surgeon of the post-mortem examination made on the horse, I have no doubt that the latter did receive an electric shock, and that probably this shock was the determining cause of death, but that, nevertheless, the shock could not have been a very severe one, and I am inclined to attach much weight to the veterinary surgeon's expression of opinion that the dilatation of the heart may have been a predisposing cause of death. In order to further elucidate the above, I attach a rough tracing of the locality in which I have marked the street box *a*, the small pipe *b*, and the larger pipe *c*.

My explanation of the occurrence is as follows: In the first place, the soil at Bournemouth is of such a nature that it is very difficult to get what is technically known as "good earth." There are alternate layers of sand and clay, and either of these may, under certain conditions, oppose great resistance to the passage of electricity. The soil in which the street box, *a*, and the pipe, *b*, were placed was a peaty sand, but probably a layer of clay exists at no great distance below. Secondly, the accident happened during the progress of a thaw after a very severe frost. Now, water in the solid form is not nearly so good a conductor as it is when liquid, and the juxtaposition of masses of thawed and masses of frozen ground may have greatly influenced the direction and amount of current flow. It is just possible that the small amount of heat produced by the current in the wires contained in the pipe may have determined a more complete thawing of the ground directly above the pipe than in other parts. Thirdly, the pipe which appears to have been directly charged from the cable was only 34ft. long and 1½in. in external diameter, and was not metallically connected to the larger pipe, but terminated at the brickwork of the street box. Even in soil of a highly-conducting nature it would, I consider, be possible to appreciably charge such a short length of pipe by contact with a high-pressure electric wire. Owing to the special conditions above referred to, the potential of the surface of the ground immediately above the pipe appears to have been appreciably affected, and the horse seems to have placed its hind feet upon this charged surface. At the same time one fore foot would be 4ft. or 5ft. distant, and very probably in contact with more freely conducting soil. A current from the charged to the uncharged, or at any rate less highly-charged ground, therefore, passed through the body of the horse.

That any such result as the death of a horse should have followed from so indirect and limited an application of electricity is indeed an extraordinary occurrence, but while the field of enquiry it opens to view must be carefully studied, and any additional precautions which may after due consideration be thought necessary firmly insisted upon by the Board of Trade, I do not think there was any appreciable danger to human life in this case. Experience in many countries has shown that horses are peculiarly susceptible to electric shock, and a horse neces-

Digitized by Google

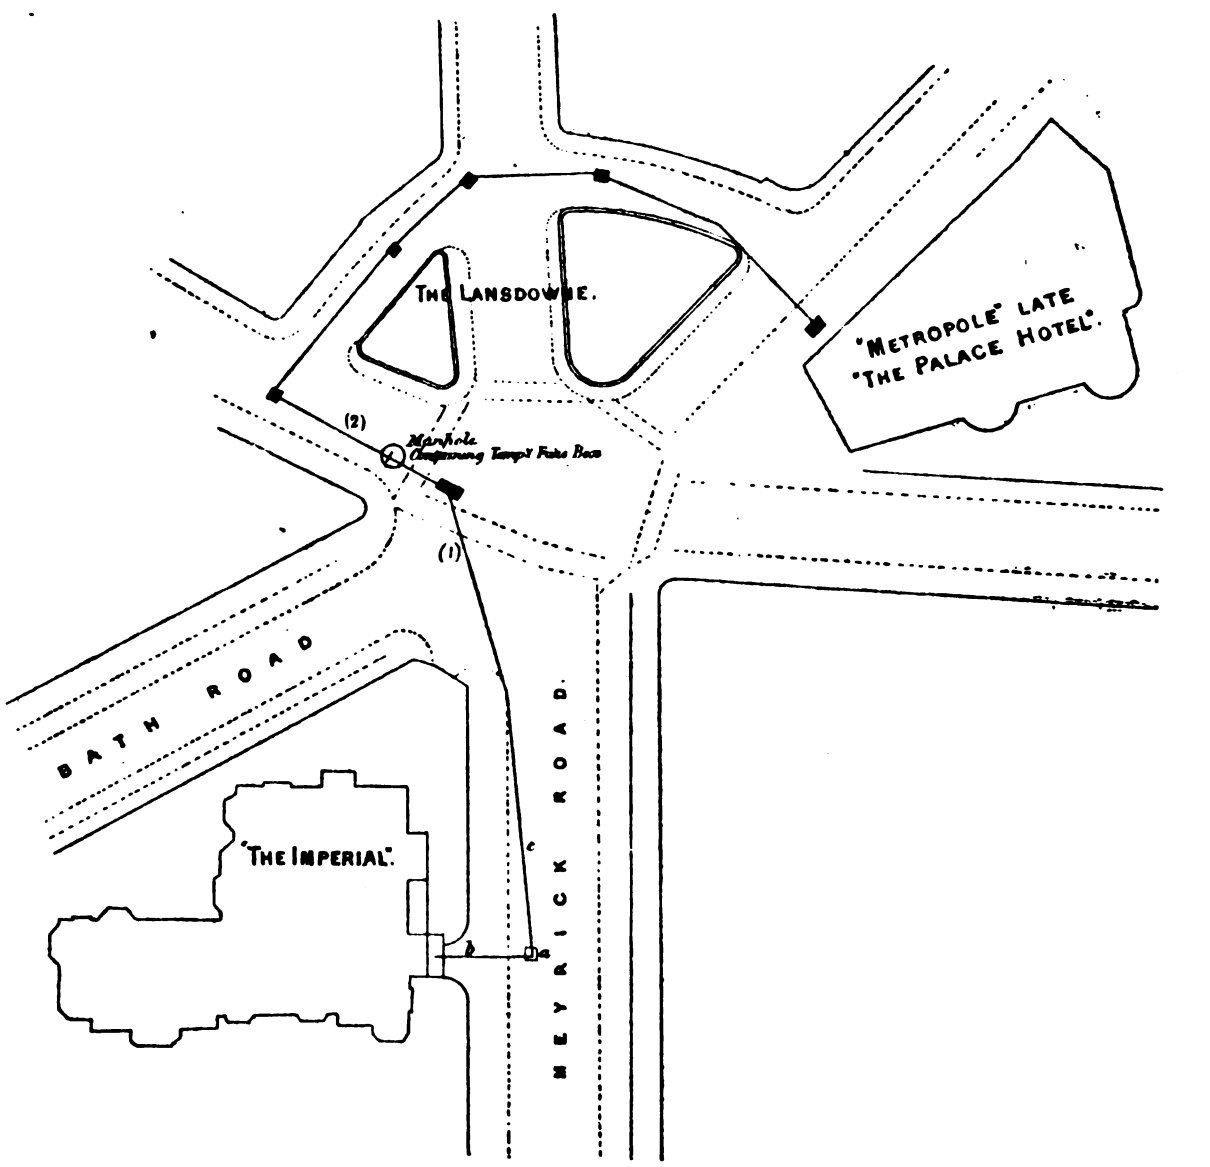
sarily, even when at rest, is in contact with the earth at points much further apart than are simultaneously touched by men, while the iron shoes of the former and its greater weight ensure a more perfect contact where it does touch. These differences are well brought out by the testimony of the men who extricated the horses. When they touched the bridles they felt a shock, because their feet were resting on the ground about 7ft. away from the hind feet of the horses; but no one of them appears to have been conscious of any shock at all except from contact with the horses. The suggestion that people inside the omnibus might have been injured by an electric shock is quite untenable. It is, of course, needless to point out, however, that many people's lives may be jeopardised from the result of an electric shock given to a horse, and that on this account alone it is essential that all danger of such an occurrence should be avoided.

I cannot acquit the electric lighting company of blame in the matter. They had warning by their own tests that a defect of insulation existed on this circuit, but they had taken no steps to localise and remove it, although the insulation of the circuit was considerably below one megohm. Also on the very day of the accident, as will be seen from the attached copy of a report from one of the foremen in the employ of the Corporation, they had received a warning of the state of things, which they should at once have attended to. I must also point out that in my opinion the use of such small and thinly-insulated wires carrying high-pressure currents for electric lighting is most injudicious. The cable which failed on this occasion is apparently exactly similar to that which caused the death of a lineman on the House-to-House Company's system rather over a year ago, and other companies have, I am informed, experienced trouble with cables of this size and description.

In order to prevent any recurrence of similar accidents the company should, in my opinion, take the following steps: (1) Immediately replace all cables used for high pressure similar to that which caused the accident by larger cables, having a thickness of insulation of not less than $\frac{1}{16}$in. of best quality indiarubber or some equally efficient material. (2) Connect together all the pipes in which high-pressure cables are contained, and wrap the cables where they pass through street boxes with a sufficient covering of sheet lead, or encase them in iron cases also connected with the pipes, so that the cables should be enclosed throughout in metal casing in connection with earth over the full extent of the system. (3) Submit to the Board of Trade for approval, as required by Regulation 10, some efficient pattern of leakage indicator. 4. Take immediate steps to localise and remove any defect of insulation which may occur on their circuits.

Mr. J. T. King, M.R.C.V.S., reported as follows to the Town Council of Bournemouth:

I beg to report that, acting on your instructions, I have, in conjunction with Mr. Goodall, F.R.C.V.S., of Christchurch, and Mr. Blake, M.R.C.V.S., of Bournemouth, made a post-mortem examination of a grey mare, the property of Mr. Melton, which was reported as having died suddenly, January 8. We found a bruise extending along the right side of the body from about the seventh to the twelfth rib. There was an ecchymosed spot on the corresponding side of the pleura. There was marked hyperaemia of the muscles of the anterior part of the body; the muscles of the posterior part were analmic. The abdominal organs were healthy. The spleen was slightly enlarged; the substance was examined by the microscope and was found to be healthy. The lungs were congested. There was dilatation of the right ventricle of the heart; the valves were normal. The blood was fluid and black in colour. The brain was healthy. Rigor mortis was present. I am of opinion that the post-mortem appearances were consistent with death being caused by an electric shock. I am further of opinion that the dilatation of the heart may have been a predisposing cause of the death of the mare.



The Bournemouth Accident.—Rough Plan Showing Service to Imperial Hotel, Lansdowne Crescent, and Metropole.

The following is the report of Mr. W. Elcock, the foreman:

Carter J. Hooper reports that he went to the Imperial to collect ashes about 7.30 a.m. this morning; when he arrived there his horse became startled, as if by shock, and he says that he himself felt the shock of electricity in his legs, also in his arms. J. Scott, assistant ash-carter that was with him, reported as above mentioned to me. I at once sent him to the offices of the electric light company in the Albert-road to report the same, which he done—viz., to some young person that was in charge of the offices at the time.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XI. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

THE DANGERS OF A WEAK HEART.

Some of the daily newspapers have lately created a languid kind of interest in a scare as to the possible dangers of electricity to human life from defective wires or bad workmanship, and if the result should be that the latter become wholly eliminated, the complaints now made—though perhaps exaggerated—will have served a useful purpose.

We imagine, however, that even a "big gooseberry" season would hardly cause a non-technical paper to comment in this fashion upon the somewhat extraordinary incident which lately occurred at Bournemouth, when an omnibus horse lost its life on the street apparently as a result of direct electric shock. One cannot altogether envy Major Cardew his task of endeavouring to find, on behalf of the Board of Trade, a reasonable solution of this occurrence; it is, of course, quite easy to imagine certain conditions under which the incident (the details of which are doubtless fresh in our readers' minds) might justly be ascribed to electric action, but whether such necessary conditions were actually present in the Bournemouth case was the precise point which had to be examined into and reported on by the Board of Trade technical adviser. On another page we publish the conclusions to which he was led after careful investigation on the spot; and from this may be gauged the measure of success he has achieved in finding out the why and wherefore of the matter.

Now that the much-lamented Sherlock Holmes is no longer with us to unravel intricate problems, Major Cardew is, perhaps, to be congratulated upon his analysis of cause and effect in the Bournemouth "mystery," more particularly as he had not the advantage of previously carrying out the synthetical process. There seems to be no doubt—as a result of his investigation—that a slight defect existed in an underground electric light cable carried in an iron pipe near the spot where the unfortunate horse fell down; and it is conceivable in such a case that the iron pipe (which was *not* metallically connected to the large pipes of similar type containing the street mains, but terminated in one side of a brick junction chamber) might become part of the branch circuit in proportion to the resistance of the leak. But one would suppose that an "earth" of this kind, especially on the positive conductor, would at once have made it self-evident in the central station. Major Cardew's explanation of the way in which the leak was, as it were, confined within a narrow area is so ingenious as to be hardly credible.

Not only was the current prevented from passing back to the station through the "electrical cesspool," as it is sometimes facetiously called, or the lower main body of earth lying between the two points, but it was even restrained from traversing the ground surface. In the former case, Major Cardew lays the blame upon the Bournemouth subsoil, truly excellent from a sanitary point of view, but almost useless as an earth return. The second cause of localising the charged area was, he thinks, the frozen condition of the surrounding ground. Apparently, the current was hemmed in without

Digitized by Google

possibility of dodging the hard spots where the surface moisture (to a depth of a foot or so) had frozen.

Although such an explanation may quite conceivably hold good, yet we cannot help thinking that Major Cardew showed wisdom, at least, if not a disposition to "hedge," in emphasising the fact that the horse—as shown by the post-mortem examination—could not be considered healthy, or a fit subject for the mildest of electric shocks. If the unfortunate animal's life were insured, we might anticipate a lively discussion as to whether its cardiac dilatation were the immediate or proximate cause of death.

We do not hold a brief on behalf of the electric light company, and would certainly refuse to consider satisfactory their choice of insulation for the branch mains from junction-chamber to transformer-house in the adjacent hotel; but Major Cardew's report is, we think, unduly severe upon them in several respects. It seems that notice had been given, prior to the fatal "horse" incident, of slight shocks being felt at the same spot, and immediate examination was made without result, though the cables themselves were not specifically made. The amount of leakage was so slight that it did not manifest itself in any way at the supply station; otherwise, of course, the whole circuit would have been cut out for a complete test.

The idea of there being practically an insulating wall of frozen ground which encircled the iron pipe and area affected, has such an air of ingenious novelty that one grasps it with interest and a feeling of indebtedness to Major Cardew. As for the poor horse, we have not the least doubt that it was a willing victim in view of what electricity has done and will do for the equine race in tramway work. A would-be humourist has even suggested that, in order to show the gratitude of altruism, the animal fell down so that its Harness might assist in passing a current through its body of sufficient strength to complete the happy despatch.

The question of danger to human life proved, fortunately, outside the mark altogether; and, of course, it would under such circumstances hardly be feared in any way. The leakage of a current at high pressure sufficient to effect bodily injury could not well occur in a manner that would introduce into the circuit any ordinary individual passing along the street, or engaged in duties unconnected with the electrical work. Major Cardew's inquest has therefore been held upon a horse only, and it need not be supposed that at any other time a human being might take the animal's place.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTRIC LIGHTING AT DOVER—A CORRECTION.

SIR,—In one of the "Business Notes" in this week's issue of the *Electrical Engineer* you call attention to a report by Mr. Slingo upon the Board of Trade by-laws for the supply of electricity in the borough of Dover, stating that "several small alterations were recommended, but the report generally was a strong objection to the proposed sanction of overhead wires." As the paragraph and report have given rise to a wrong impression that overhead wires were intended to be used, permit me to state that had Mr. Slingo made himself acquainted with the tenor of the description of the system to be employed which the Board of Trade requires from electricity supply companies before issuing their permit to undertake the work, he would have ascertained that it was never contemplated to use overhead wires at Dover, and saved himself the trouble of writing a lengthy criticism on a system of distribution so entirely "in the air."—Yours, etc.,

A. J. LAWSON.

London, February 10, 1894.

A PERSONAL EXPLANATION BY MR. KAPP.

SIR,—Your contemporary the *Electrician* contains a note about me which calls for correction, and I would ask you to allow me a little space for this purpose. Perhaps I cannot do better than send you for publication the copy of a letter which I have addressed to your contemporary. It runs as follows:

"Sir,—I saw with much surprise an announcement in your current issue that I am about to leave England. I wonder it has not occurred to you that before publishing a statement which, if erroneous, may injure my professional relations in this country, it would be proper for you to make quite sure your information is correct, and this you might have easily done by enquiry at my office.

"I cordially dislike the importation of personal matters into a scientific paper, but as your statement is calculated to alienate my present and possible future clients, I would ask you to allow me to make the following corrections: (*a*) my leaving England shortly is not even in contemplation; (*b*) my leaving it at a future date (which will give me ample time to finish all the work I have in hand) is in contemplation, but is by no means certain; (*c*) I have been offered an important appointment in Germany, and am in negotiation about it, but the matter is still pending, and will not be settled either way for about a month. Whether I shall leave England or not I do not even know myself at present, so that your statement was certainly premature, and may perhaps also turn out to have been incorrect.—Yours, etc."

It will be clear from the above that the *Electrician* has published as an established fact what is as yet merely a possibility, and I trust you will find space for this letter so that I may set myself right with my professional friends and clients, who might otherwise think it strange that I have up till now kept silent on this point.—Yours, etc.,

GISBERT KAPP.

31, Parliament-street, Westminster, February 10, 1894.

BLACKPOOL CENTRAL STATION.*

BY JOHN HESKETH.

Introduction.—I wish to disclaim from the very first any desire to draw attention to any one system or station, excepting with a view to provoking discussion upon the very broad question of central-station design. If the laying before this society the details of the plant and system at Blackpool conduces to a discussion on this important question, then, as one instance only out of the many of similar design, it may be allowed to retire or merge itself into that particular class of station.

Historical.—So far back as 1879 Blackpool first tried electric lighting by means of Siemens arc lamps each run from a separate dynamo. When it is remembered that the original dynamos and lamps were burning until August last, the character of the work carried out is evident. But the demand for a more general application of electricity to both public and private purposes called for an extension of the scheme, and the Blackpool Electric Lighting Order, 1890, granted powers to the Corporation to lay down works for the supply of electricity from a central station. The town is, as most of the members are aware, long and narrow; the promenade (north to south) being some three miles in length, and the width (west to east) about one mile. The system chosen, therefore, was high tension, and the works were proceeded with on that scheme.

Site.—The building in which the plant is erected is situated in what was the central storeyard, a site in every way suited for the purpose. It is near the centre of the promenade, and

* Paper read before the Northern Society of Electrical Engineers. An illustrated description of the buildings and plant was given in our issue of October 20, 1893.

Digitized by Google

a railway siding passes the coal-bunkers. Ample room is available for extensions when necessary. The soil all round Blackpool is mainly peat, in some places being varied by silt and marl. But fortunately there is a mound of clay rising just under the site of these works which enabled us to find solid foundations easily. Clay was met at 3ft. below the ground-level and continued as far as we cared to test, 24ft. being the lowest point tried.

Buildings.—The buildings are erected in two spans—one forming the boiler-house, and the other the engine-room. The boiler-house is 68ft. by 125ft. 6in., and the engine-room 55ft. by 125ft. 6in. As these two buildings run approximately parallel and divide the land, it will be seen that to make extensions is a comparatively easy matter: a false end can be readily run up until any extensions are finished. The chimney is placed in the position indicated on the plan, with a view to facilitating any cleaning of main flues, etc., and of having an equal division of boilers on each side in case of extension southward.

The System.—As before mentioned, the systems adopted are high-tension continuous current for the public arc lighting and high-tension alternating (2,000 volts) for private lighting. Transformers to feed separate installations, or groups, are put down as circumstances demand. The station contains the following plant: (1) 100-kilowatt alternator; (2) 50-kilowatt alternators; (3) Brush arc dynamos, 55 lamps each. The general arrangement of this plant is shown on the accompanying plan.

Details of Plant: Three Double-Flued Lancashire Boilers (manufactured by Messrs. Galloways, Limited, Manchester). Shell, 28ft. long by 7ft. diameter; heating surface, 852 square feet; grate area, 36 square feet; plates 11-16 thick. Butt jointed with inside and outside cover strips. Flues, two in number, 2ft. 9½in. diameter × 15-32in. thick; five "Galloway" cone tubes 10½in. diameter at top, and 5½in. at bottom, placed in each flue. End plates, 11-16in. thick. Fittings, all Hopkinson's own make. Two out of the three boilers are fitted with a combination of Meldrum's forced draught and Proctor's mechanical stoker. The third is fitted with Proctor's stoker only. Feed-water apparatus: Two tanks, each 10ft. high × 7ft. 4in. diameter (capacity 2,640 gallons) are fixed between the boilers. From these the water is fed by two duplex ram pumps, manufactured by Pearn and Co., and capable of delivering 1,500 gallons per hour each. Two feed-water heaters by Fowler and Co., Limited, Leeds, each capable of heating 1,500 gallons of water per hour to 78deg. C.

Engines.—One compound coupled horizontal non-condensing engine, by Fowler and Co., Limited. Cylinders, 15in. and 24in. by 30in. stroke. Horse-power, 200 i.h.p. at 90 revolutions, with steam pressure of 125lb. per square inch. The valves are the ordinary slide valves, the expansion-valves of both cylinders being controlled by Hartnell's patent governors. Flywheel, 14ft. diameter, driving, by eight 1½in. cotton ropes, a 100-kilowatt alternator. Two compound coupled horizontal non-condensing engines, by Fowler and Co. Cylinders, 11in. and 18in. by 20in. stroke. Horse-power, 100 i.h.p. at 120 revolutions, with steam pressure of 125lb. per square inch. Valves as in other engines. Flywheel, 10ft. diameter, driving, by six 1¼in. cotton ropes, a 50-kilowatt alternator. Three compound coupled horizontal non-condensing engines by Fowler and Co. Cylinders 9in. and 14in. by 16in. stroke. Horse-power, 60 i.h.p. at 150 revolutions, with steam pressure of 125lb. per square inch. Valves, as in other engines. Flywheel, 6ft. diameter, driving, by six 1¼in. ropes, a Brush arc dynamo for 55 arc lamps.

Dynamos.—One 100-kilowatt alternator by the Electric Construction Company, 2,000 volts and 50 amperes. Speed, 375 revolutions per minute, at which speed the alternations are 5,000 ⌒ per minute. Current density in armature and field, 2,000 *a* per square inch. Lubrication by special lubricating pumps. Excitation is by a series dynamo, and at full load is 122 volts and 24 amperes, or an excitation of 2·9 per cent. Rope tighteners are provided. One 50-kilowatt alternator by the Electric Construction Company, 2,000 volts and 25 amperes, similar in general design to the 100-kilowatt machine. One 50-kilowatt alternator by the Leeds and London Electrical Company. This alternator is made under the Hall-Hammond patents. It has the advantage of a sectional armature, so that a coil may easily be removed if required. All these alternators run regularly and perfectly in parallel, the synchronising current being small. Three arc dynamos by the Brush Electrical Engineering Company, each capable of maintaining 55 10-ampere arc lamps when running at a speed of 800 revolutions per minute. The special feature of these three machines is that they have been fitted with a new type of brush-holder, which is working most satisfactorily. It is well known that the original type was not all that could be desired, but the present arrangement gives promise of being quite satisfactory.

Switchboard.—The switchboard is of the Lowrie-Hall type, employing plug switches. It has proved eminently satisfactory.

Testing Frame.—For purposes of testing, resistance frames to take 100 kilowatts at 2,000 volts are provided.

Travelling Crane.—One overhead travelling crane for a load of 10 tons spans the engine-room.

Distribution.—The distribution is by means of cables insulated by vulcanised indiarubber. These are drawn into 3in. cast-iron pipes, as many as six cables being drawn into one pipe. Over 20 miles have so far been laid—the furthest point at which a supply is given being two miles distant from the station. The street boxes are of iron or brick, with cast-iron covers, and as the high tides are so frequently over the promenade to a depth of some 2ft. to 3ft., it is useless to try to keep the conduit dry. We find no difficulty, however, in working with the cables under water. The public arc lamps are the Brockie-Pell double-carbon lamps, erected on pillars of a design which is a modification of that in use in the main thoroughfares of Paris. The lamps are burning steadily and well. Transformers are placed wherever possible to feed three or four consumers, but in many instances this is not possible, and a separate transformer for each consumer is fixed. We use at present transformers made by the Electric Construction Company, the Leeds and London Electrical Engineering Company, and Johnson and Phillips.

Meters.—We use the "Shallenberger" and the Thomson wattmeter.

Extensions.—The demand has been so great as to justify our undertaking an extension of plant for private lighting. This will comprise one 100-kilowatt and a 200-kilowatt plant, each with boiler feeding direct, or into the main ring. One feature of the extension is the omission of any special plant for series arc lighting. It is a well-known fact that Mr. Ferranti's latest transformer for commuting alternating into vibratory currents and transforming constant-pressure currents into constant currents at varying potential, is being successfully developed; and it is in the hope that it will prove the success it promises to be, that we are deferring laying down any new arc plant.

Notes on the Working of the Plant.

It is not my intention to go closely into the question of the cost of working the plant at Blackpool. The time has not been long enough for a reliable deduction to be made on this head, but if any value can be attached to them I append the figures taken for four weeks in December, 1893:

	Week ending December, 1893.			
	9	16	23	30
Units output	2,980	2,870	2,830	3,119
Coal	19 t. 5 c.	16 t. 16 c.	16 t. 13 c.	17 t. 12 c.
Pounds per unit	13	13	12·7	12·6
Water, gallons	48,625	31,450	34,530	38,673
Pounds per unit	163	109	122	124

Cost.	£ s. d.	£ s. d.	£ s. d.	£ s. d.
Coal	16 15 9	15 7 6	12 5 0	13 11 6
Water	2 9 0	1 12 0	1 15 0	2 0 0
Oil, etc.	1 5 0	0 17 6	0 17 6	0 15 0
Wages	11 1 3	12 6 7	13 12 8	15 0 3
Management and accountants, etc.	7 12 9	8 15 0	7 3 1	7 19 0
Total	39 3 9	38 18 7	35 13 3	39 5 9
Cost per unit	3·15 pence.	3·25 pence.	3·0 pence.	3·0 pence.

Necessarily, a few weeks' readings taken alone, as these are, cannot be taken as any criterion of a year's working, but the first portion of the analysis is interesting. The coal we used during these four weeks was a mixture of Wigan 4ft. and Scotch duff—in the main, not a very good coal, as the majority of the duff was carried over the bridge by the forced draught. Then, again, the banking of the fires is an item for great consideration, as we do not yet run the 24 hours. The water recorded includes that used for every purpose, so that a deduction must be made for cleaning out boilers, etc., if a measure of the evaporative efficiency is to be obtained. If, however, I may be so permitted, I will reserve the question of costs of working this plant for a future communication.

To pass on now to the main point of discussion I desire to raise by this paper. Given an area of supply such as Blackpool, with two classes of lighting, what general design of station is best calculated to give satisfaction? The boilers and steam-raising plant employed are of a well-known and tried type, the engines and dynamos equally reliable; and the only question that is likely to be raised is that of general efficiency and reliability. I strongly incline to the opinion that reliability is worth the sacrifice of a percentage of efficiency ranging from 5 per cent. upwards. With such a plant as this—boilers whose steam-raising capacity is known to a nicety, engines that will run for months without a stoppage, and dynamos on which a coil scarcely ever goes—an engineer can regard almost complacently a plant efficiency of 65 to 70 per cent. Then, too, the question of parallel running is one which must bias the design of a station. If it is necessary with some dynamos to put a marine type of ammeter on the circuits to prevent the synchronising current from being too apparent, while with others the lightest of pointers scarce moves over five scale divisions, then the difference in the result on the dynamos

Digitized by Google

themselves after 12 months continued parallel running must be evident.

The question of distribution is one having many aspects. The advocates of the simple two-wire system have now many opponents, but with a high-tension network designed to feed each transformer from two directions, and with banked transformers feeding into a similar low-tension network, the variation in voltage (which, after all, is the public's criterion of successful lighting) is reduced to a minimum. The question of mains, and their insulation, too, is viewed differently by different engineers. My own opinion is that it is useless endeavouring to lay watertight conduits, and that the endeavour should be to have cables to run as well in water as out of it. High-insulation resistance is an admirable thing, but it can be obtained in too many ways to be satisfactory in itself. It is with a view to provoking discussion on these general questions of design that I venture to mention in detail a few of the alternatives offered to the plan adopted by us at Blackpool. To begin with the

Boilers.—The advocates of multitubular boilers are numerous. They claim a higher all-round efficiency and economy in space. But I question whether all their contentions are maintained in practice. There are stations where, after having used multitubular boilers, it is found advisable to lay down Lancashire boilers to take the real duty of the station and leave the multitubulars for rapid steam raising. With efficient feed-water heaters, or good exhaust-steam injectors, and a well-tried mechanical stoker, I question whether the old type of Lancashire boilers can well be beaten.

Mechanical Stokers.—The type of stoker used by us is that manufactured by Mr. J. Proctor, of Burnley. The alternatives brought before us were Bennis and Vickers's stokers.

Steam Ring.—The steam-pipe is erected, as will be seen from the plan, on the ring principle, each boiler feeding into the ring. By this means each engine can be fed from two directions, and risk of breakdown is reduced to a minimum. The alternatives suggested are many. One is to feed direct into each engine from its own boiler with by-passes in the event of a boiler or engine being laid off. This system has its advantages, but I incline to the opinion that the ring is preferable.

Engines.—In approaching the question of engines, I am aware that the field for discussion is very wide indeed. Slow-speed horizontal, moderate-speed verticals, central-valve verticals—all have their advocates. But it must be remembered that Lancashire is, above all places, the home of slow-speed horizontal engines. It is only natural that where space is available, the tendency should be to adopt that class of engine which for regularity and reliability has so long proved its fitness in this and other districts. I am led to believe that central-valve engines require somewhat skilled labour and careful supervision, whereas any Lancashire mechanic is sure to have had years of experience with slow-speed horizontals. Moderate-speed verticals are beginning to gain ground fast, and they, if any, are the rivals of the slow horizontals, especially where space is a consideration and direct coupling is desired.

Rope Driving.—Here again is a fruitful source of controversy. The question resolves itself into (1) three-strand, as against four-strand ropes; (2) separate ropes for each groove, as against an endless rope with a jockey pulley. The advocates of each of these systems naturally say their own is best, but it is for practice to have the last word. We find three-strand ropes to run very well indeed. Some turn round in the grooves, while others do not. Direct coupling is, however, coming much to the front. Its advocates claim, and with some amount of truth, a considerable increase in efficiency as against rope driving. Reliable data on this point will be much welcomed.

Alternators.—I have previously stated my opinion that I consider reliability to be worth from 5 per cent. efficiency, and that good parallel running is another important factor. The alternators of the type we have here run most perfectly in parallel. I have never seen machines take less synchronising current. Of course, with all alternators running in parallel a great deal depends upon the engine. It is not so important to regulate by the excitation as by the engine stop-valve; and experiments in parallel running fail frequently because the dynamo speeds are not similar before paralleled, and therefore, after paralleling, one engine is constantly trying to pull itself out of step. It is a mistake electricians are prone to make—this regulating from the dynamo end simply—but it is not a successful way. The points one would most wish to have a clear and settled opinion upon as to alternators are: What efficiency should we reasonably expect an alternator to give? How long should it be able to run (at that efficiency) before a coil goes, or a breakdown occurs; and what synchronising current should be aimed at as good practice? It is not good enough for dynamo-builders to say, "This efficiency is indispensable; never mind coils going, they can be easily replaced." We who run central stations want dynamos that will run the year in and out without the crane once being near it, and if we can incidentally obtain 91 or 92 per cent. efficiency so much the better. But if we buy this efficiency at a cost of a stoppage once a month, or even once a quarter, it is dearly bought. Credit before efficiency; but both if possible.

Switchboard Arrangements.—Under this head, of course, are included all instruments for measuring the output. This important feature is often dealt with by simply taking quarter-hour readings, averaging out, and finding the apparent watts. But although this may be an approximately correct method on circuits with small magnetising currents, it is not satisfactory even with them, and on circuits where both alternator and transformer have a sensible induction it is far from accurate. We employ a Thomson wattmeter on each circuit to check the readings taken every quarter of an hour. The error in apparent watts over the watts recorded by the meter vary from 5 to 15, or 20 at lowest loads. The Mangarini wattmeter is another form which I believe very good for this purpose. Our voltmeters and ammeters are all Nalder's make. These we check periodically by the standard dynamometer and multicellular voltmeter.

Mains.—The draw-in and draw-out system has many advantages over the buried conductor. But there are now many cables competing with those insulated by vulcanised indiarubber, so that even with a draw-in and draw-out system there are many alternative cables to decide between. Single and concentric each have their advocates—indiarubber, guttapercha, and paper, as insulation, each having advantages of their own. The only serious rival of indiarubber-covered cables, to my mind, is the paper insulation of Mr. Ferranti's. Made up in concentric form and lead covered or steel taped, this cable seems to stand any working pressure. But vulcanised indiarubber will do this if the best rubber be used, and it is only on the point of lasting qualities that one can make the crucial comparison. As I before said, our cables are and have been running under water for some time, and we have had no trouble with them. The same thing can be said, I believe, of paper insulation; and were it not for the established repute of vulcanised indiarubber, I can easily conceive that paper would be an even more serious rival to it.

It has been with the hope of eliciting the experiences of the members on these various questions that I have ventured to place this effort before them.

Discussion.

Mr. Fawcus, after complimenting the author on his paper, said that some short time ago the question between high and low tension seemed to be rather going in favour of the low-tension system. One successful station had influenced many others, and it seemed to be tending in that direction, but now better counsels had prevailed, and the high tension was fast gaining ground. On the particular system discussed that night he would like to ask Mr. Hesketh how the double service to each consumer was laid? If it meant laying special mains to get a double service, he did not consider it worth the extra cost. The question of parallel running, too, had never yet been settled, and he, like Mr. Hesketh, would like some basis on which they might work. On the question of boilers he considered that Lancashire boilers were far preferable to multitubular boilers, except for rapid steam raising. For general work and efficiency he considered that nothing could beat the Lancashire boilers. He did not quite agree that direct coupling was the advantage that it was claimed. It immediately necessitated high speeds in the engine and lower speeds in the dynamos, and therefore lighter working parts in the engine, and heavier and more expensive make of dynamo. But in cases where space was the great consideration, moderate slow-speed vertical engines might be found of advantage.

Mr. Rider said he would like to ask one or two questions, although he was scarcely prepared for extensive criticism. He presumed that the points raised by Mr. Fawcus as to the double service to each consumer or bank of transformers was gained incidentally, and that no special mains had to be laid. Next as to excitation. If the field magnets are excited by constant current, why should any false watts be present? He rather gathered that at present no low-tension network was laid. Was this so? He would also like to know how the pressure was maintained constant and an indication given from the far end of the mains. He noted that each dynamo had its own exciter, and asked if it were necessary when running in parallel to regulate by each exciter, and if it would not be advisable to have the field magnets excited in parallel, so that one regulation would serve for all the machines? Commenting upon the Hall-Hammond type of alternators, he asked if the fact that the armature coils were wound on projecting laminated pieces caused any fluctuation in the exciting current?

Mr. Browett said that the question of horizontal or vertical engines was often decided by the makers by the consideration of space. The same could also be said as regards ropes as against direct driving. He considered that a moderate-speed vertical engine having the few working parts of the horizontal slow-speed engine, was in some instances preferable.

Mr. Corlett considered that there was a great deal to be said in favour of direct coupling. One incidental advantage for a place like Manchester was the ease with which the plant could be started. He disagreed to some extent with the advocates of high-tension systems. He considered that the low-tension system was far more simple, and that the maintenance of the insulation of the mains was easier. Again, both motors and arc lamps could be more successfully run off low-tension direct-current mains. He did not think that any alternating-current motors of a periodicity

Digitized by Google

above 40 were to be got. Then, again, the necessity for the constant day load made the use of a battery a great convenience in a low-tension station.

Mr. Cowan spoke as to the efficiency of condensing as against non-condensing engines, recapitulating the figures given by Mr. Willans as to the saving at full load of 18 per cent. and at low loads of 40 per cent. On the question of boilers he considered that we should not lose sight of the fact that Lancashire boilers required more time to get up steam. He would like to know what pressure of forced draught was used at Blackpool.

Mr. Fawcus mentioned that he had that day received particulars of the Gothenburg station, where the average amount received from the consumers was 2¾d. per unit, and even at this revenue the company was paying 5 per cent., and that with coal dearer than it is in Lancashire.

Mr. Hirst would like to know how the meters in use at Blackpool worked, and further details of them. Speaking on the question of motors, he had just returned from Switzerland, where 1,200 h.p. was being distributed on the alternating system of mains by motors varying from $\frac{1}{10}$ h.p. to 10 h.p. He mentioned the system used by the Oerlikon Company, who employed the condenser in starting their motors, and switching over after attaining synchronism.

A Member spoke on the saving of labour by using direct coupling. With direct coupling one man could generally manage three sets of plant, whereas with rope driving it generally required one man to each set. He understood that with direct-driven plant there was considerable difficulty in running in parallel, and that at Bristol and Derby coils had given out on attempting to so run. He would like to have an expression of opinion as to the points to be observed in parallel running.

Mr. Lindley said that he would like to make a remark or two as to the running at Bristol and Derby. There were two ways open for them to obtain varying motions on the cranks. One was to have the cranks directly opposite, or at right angles; the other was to throttle the steam to some extent. But he was more than ever struck with the uncertainty still existing on the subject of parallel running. They had tried heavy flywheels and light flywheels at Derby, and although they had run in parallel it was only after some difficulty. He would like to know whether the difficulty was with the dynamos or with the engines.

Mr. Hesketh, in reply, said that many of the points were of extreme importance and interest. Some of them called for specialists' attention rather than for his, but he would endeavour to reply to the majority of the questions asked. Replying to Mr. Fawcus's query as to the double service to each transformer substation, it was gained incidentally. Most blocks of buildings are built in squares, and when all shops require a service it is very easy to feed each transformer both ways. He thought that two of Mr. Rider's questions bore upon each other. Mr. Rider asked how it was that a constant current should not give true watts when the current and the voltage were multiplied, but later asked, did not the armature react on the field magnets in the Hall-Hammond type? It was observing this reaction which led to the investigation of the false watts in excitation. Mr. Hesketh agreed with Mr. Rider that in parallel running it was better to regulate the field magnets in parallel. He could not quite agree with Mr. Corlett's contention as to the superior simplicity and flexibility of the low-tension system. Neither was he quite sure that the insulation of low-tension mains was more easily maintained. He believed that there were representatives of low-tension systems present who could speak better on this point than he could, but for the simplicity of the high-tension system he could speak. Mr. Corlett had said that there were no alternating-current motors to be got, whereas he had received almost weekly offers of alternating-current motors from $\frac{1}{10}$ h.p. to 8 h p or 10 h.p. for alternating currents of a periodicity from 40 to 120 On the question of the use of batteries and shutting down the station for the load to be taken by the batteries, he thought he was quoting the words of Mr. Siemens, who some two years ago said, "that batteries would only be used in toy stations to feed restricted areas," and that for their extended use he had not much faith. On the question of parallel running, referred to by Mr. Browett and Mr. Lindley, some electricians said it was purely a mechanical failing when alternators would not run in parallel. Some mechanical engineers said it was purely an electrical fault. He considered it was both. Alternators were to be seen running in parallel driven direct by central-valve engines, by vertical engines, and by slow-speed horizontal engines The alternators, too, varied in type, and might have a revolving field with an armature, in which there was no iron, as in the Mordey alternator; others with iron in the field, such as that of the Hall-Hammond type. He believed that the experiments made in the four city stations recently proved that half-a-dozen different types of alternators driven by an equally varied number of engines would run well in parallel. One point was worth noting in this question of parallel running Given a slow-speed horizontal engine with perfect valve gear, and with a card approximating to a theoretical figure where the cut off was sharply defined, the compression slight, and the admission line perfectly sharp, if it only had a light flywheel, and was driving an alternator without iron in the armature, he doubted whether parallel running could be attained; but if a vertical engine with a very imperfect diagram in which the cut off was ill-defined, where compression was great, so that the admission line was scarcely more than a pound or two, then if they were driving an alternator similar to the previous one it would run in parallel if proper precautions were taken. But the first engine would drive alternators of a certain type in parallel. It was a question both of the mechanical power and of the electrical capacities of the dynamo. He believed he was right when, with reference to the Bristol and Derby difficulties, he attributed some of the difficulty at least to insufficient care in arriving at perfect synchronism before paralleling the alternators. The two alternators might be running exactly at the same speed, but one might be a fraction of a phase behind the other. The synchronising current when paralleling would be sufficient to blow the fuses, and it was only when they had the maximum points of the peaks exactly coincident, and the speeds absolutely equal, that it was possible to parallel successfully. Some alternators would pull themselves together in paralleling with a large synchronising current; others would not. The fact that coils had given out at Bristol and Derby accentuated the importance of having some fixed data on which to work as to mechanical strength *versus* high electrical efficiency.

A vote of thanks terminated the proceedings.

INSTITUTION OF ELECTRICAL ENGINEERS.

SOME NOTES ON THE ELECTRIC LIGHTING OF THE CITY OF LONDON.

BY MAJOR-GENERAL WEBBER, R.E., C.B.

(Continued from page 169.)

Capital Expenditure.

The question of raising capital for electricity supply companies has not differed much in its conditions from other sister industries. This paper would be less instructive if that part of the subject was overlooked, and it is noteworthy that, even with a field for the supply of electricity in which the gas company had a gross income of over £370,000.* Even in 1891 it was not thought prudent to do what is called "go to the public," in the first instance, with a plainly-stated prospectus. Such a statement most certainly would have shown that the supply of electricity to the City should be an undertaking affording as sound an investment as could be found anywhere, and also one which at an early date, under the operation of the sliding scale already alluded to, would allow of the cost of the current being reduced below the maximum of 8d. As we all know, a very old way of commencing to raise capital has been brought out under a new name—namely, by the starting of a "pioneer company," which is one way of getting an instalment of capital together to make a beginning. Of course, there is no engineering justification for it, but the financial physician has prescribed it, and hence this first capital must be spent with a primary object of showing that something can and will be done. The future of the undertaking from the structural point of view may become quite a secondary consideration, and, indeed, may be ignored if it interferes with the parade with which it is intended to "draw" the investing public. They (the public) have only themselves to thank if this sort of thing is necessary. Engineers and contractors have no real interest in its existence. The contracts with the Commissioners for the public lighting of the City were dated: for the eastern district, May 28, 1890; for the central district, May 19, 1890; for the western district, February 5, 1891. And they required that the main thoroughfares should be completed with arc lamps in the eastern and central districts by February 28 and 19, 1892, respectively, and in the western district by November 5, 1893. The "first sod was cut" on January 5 1891, when a junction-box was constructed on the west side of the Mansion House, with an inscription inserted in the wall. The first street was lighted in July, 1891. The arc lighting generating plant was permanently fixed in the pioneer buildings, but in other respects the installations were designed to be temporary. The two companies—namely, the Brush Electrical Engineering Company, and the Laing, Wharton, and Down Construction Syndicate—to whom, as has been stated, the provisional orders and contracts had been granted, had in February, 1891, transferred their interests, through an exploration company and an electric and general investment company, conditionally, to the City of London Pioneer Company, of which company I was appointed the engineer after the contracts had been made. These interests included the obligation to complete the purchase of sites for generating stations—one at the Wool Quay, in Lower Thames-street, the other at Meredith's Wharf, in Bankside.

Part of the consideration for the transfer of the responsibilities and liabilities of the *concessionaire* companies was in each case a provisional contract for the supply and erection of the entire plant and equipment of one temporary (or pioneer) and one permanent generating station for the supply of current to, and for the transforming of current in, each district. In similar cases the work of pioneer companies has been confined to the task of financing. Unfortunately, I think, in this case the City of London Pioneer Company had to undertake actual work, so far as the public lighting was concerned, because the time remaining—namely, about 12 months—in February, 1891, when the contracts for the central and eastern districts had to be completed, was even then very short. But these provisional contracts for temporary work

* The day and night populations of the City, respectively 261,061 and 50,652 in 1881, had altered in 1891 to 301,384 and 37,694 The day population, as compared with counties and towns in England and Wales, is larger than 26 counties, and all other towns except Liverpool, Manchester, Birmingham, Leeds, and Sheffield. Before 1891 there were 3,136 public gas lamps, costing £10,530 per annum.

Digitized by Google

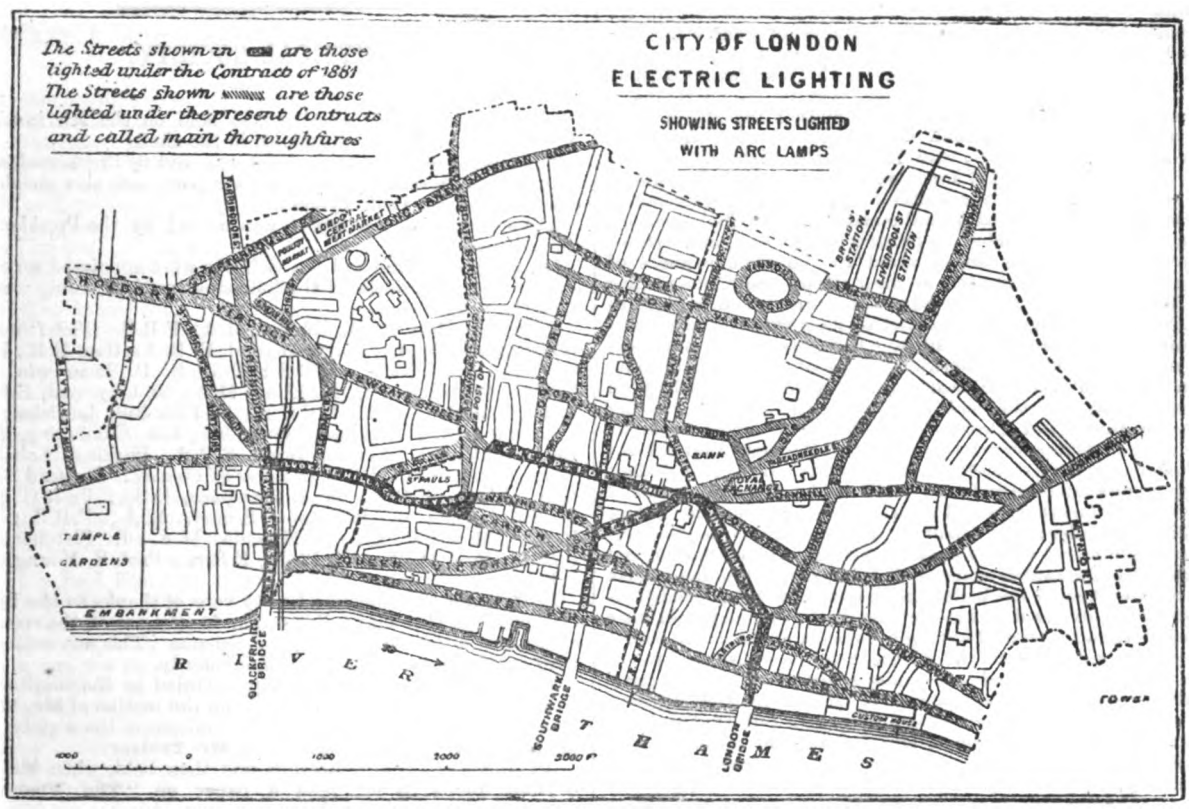
included some private lighting;* the object being the old-fashioned one, to create a display, in my opinion, at the expense of good work, and with the risk of a legacy of trouble, anxiety, and failure. Suffice it to say that in spite of every possible precaution to prevent it, no small part of this temporary work has had, or will have, to be moved or altered after having been put to work; and a large part of the money spent on these temporary installations—amounting, together with other expenses, to a very considerable sum—must be more or less wasted.†

On July 13, 1891, while the pioneer contracts were still uncompleted, all the interests acquired by the pioneer company were taken over by the City of London Electric Light Company for a further consideration, by which means the lighting of the City was, with the consent of the Board of Trade and of the City authorities, amalgamated into one undertaking instead of three, and it was at last possible to begin work in earnest, with a hope that the words "temporary" and "provisional" were past. The estimates for works upon which the capital of the new company was raised amounted to: buildings, £53,000; equipment of the three stations, £493,250; distribution, £342,850—total, £889,100. This was exclusive of the cost of the sites. The contracts for public lighting with the *concessionaire* companies which had been taken over from the pioneer company besides providing for the supply and installation of the plant and equipment for one station for each district of the City, provided also the arc and incandescent lamps for the public lighting, with their fittings, exclusive of posts and lanterns, in every respect sufficient to enable the new City company to fulfil the terms of the contracts with the Commissioners of Sewers, as follows:

Eastern district. (Laing, Wharton, and Down Company.)		Central district. (Brush Electrical Engineering Company.)		Western district. (Brush Electrical Engineering Company.)	
Arc.	Incandescent.	Arc.	Incandescent.	Arc.	Incandescent.
233	307	138	302	144	297
Total arc, 515.		Total incandescent, 906.			

Besides this, the contracts between the same parties required the work to be done for equipping the stations and providing the plant for the supply and conversion of current for private lighting to be in accordance with detailed specifications and schedules of prices. It was agreed that these details and prices were to be laid down afterwards and settled between the engineer of the company and the contractors; differences (if any) to be referred to Mr. Preece. The contracts required that the output of the Brush stations for the supply of the central and western districts, and of the Laing, Wharton, and Down Company's station for the eastern district, should, including the pioneer plant, be as follows:

	Public and other arc lighting. Kilowatts.	Private lighting. Kilowatts.
Eastern district	450	4,800
Central ,,	330	3,900
Western ,,	220	3,400
	1,000	12,100
		1,000
Total kilowatts		13,100



The Streets shown in are those lighted under the Contract of 1881
The Streets shown are those lighted under the present Contracts and called main thoroughfares

R I V E R
T H A M E S

FIG. 1.—Map of all City, with thoroughfares marked.

Adding together the cost of the contracts and estimates, and dividing by the total of 13,100, we obtain the following total cost per kilowatt:

Preliminary expenses	£8,000
Work done by the pioneer company, including some work of distribution	46,000
Extras on ditto	10,000
Contracts for the stations	493,250
Estimate of cost of completing distribution	342,850
	900,100
Add 8 per cent. for the cost of the sites of the generating stations	72,008
Total	£972,108

Namely, total per kilowatt, nearly £75.

Anyone present will realise that the preparation of detailed specifications for the equipment of an electric light supply station, both for generating and transforming requires the fullest technical description. Besides that of the boilers, engines,* and dynamos,

*The first current for private lighting was commenced on December 11, 1891, to the Mansion House, but it was more than six months after before the plant could be run during daylight hours.

† I had been through such troubles in connection with electrical and other engineering too often not to throw all my weight into the scale against temporary work of any kind. It is only before an assembly of engineers that an engineer can hope to find any appreciation of such a situation. Neither financiers nor contractors sympathise with his efforts to prevent unnecessary expenditure, except so far as it affects their own interests. The financier does not mind so long as the total expenditure is within his estimates of what the investor will stand; and the contractor need only care if he is going to accept any payment in shares, and not always then. Besides this, there is the long series of harassing engineering consequences arising out of crude, hasty, and ill-considered work preliminary to a great undertaking. Many of us have been through it, and learnt to take it as part of the day's work; but, all the same, it is always regrettable.

* Prof. S. P. Thompson's opinion, in November, 1891, on the types of engines which the contractors, under the restrictions and definitions contained in the specification, proposed to adopt, was that, while expressing his own opinion on the advantages of triple expansion, and of engines of the closed type, he confirmed entirely the conditions that the choice should be of the vertical and direct-coupled type; he postponed his final opinion until six months' running of the first group of 400 kilowatt units had been completed. It is to be hoped that he will be able now, more than two years having passed, to give electrical engineers his further experience in the subject.

Digitized by Google

there are the questions of the arrangements for transport and conveyance of coal and refuse, economising, condensing, and stoking; there are also the details of foundations, drains, subways, travellers, lifts, cranes, and the lighting of the station, as well as telephonic communication with, and equipment of, transforming sub-stations. I need not say that the preparation and agreement as to the details of specifications, after a contract is made and the total price to be paid is fixed, is a somewhat novel task for the engineer of the spending company. In this case the putting of the cart (as it were) before the horse fortunately did not end in miscarriage. The engineers on both sides* were anxious, while doing justice to their employers, to arrive at a fair and reasonable solution, and Mr. Preece could tell you that it ended in only about half-a-dozen points of difference between them and me having to be referred to him, in specifications containing nearly 120 pages of closely-printed matter. In these specifications, although the specialities of the two contracting firms were well known, nothing was laid down to confine them to their own particular make of engines, boilers, dynamos, transformers, and lamps. The contractors described to me the sizes of the units they desired to employ. They are not limited to any particular form of driving, and, as far as possible, to produce uniformity, the speeds and electrical conditions which they desire to use are allowed. Economising, automatic stoking, and condensing, and all possible accessories—including testing and switch-room apparatus and fittings—are required of capacity equal to the full output of the plant.

All the conditions of the different stages of generating are rigorously prescribed so far as the results under test are concerned. For instance, it is laid down in the specifications that, after providing for all extraneous steam consumption and waste, the standard of consumption of coal, including the steam used in the condensing pumps, shall not exceed 5lb. for the high-tension alternating currents, and 7lb. for the high-tension continuous currents, per Board of Trade unit delivered at the terminals of the primary mains in the stations. Amongst the extraneous uses of steam to be excluded from the above basis are included that used for the power expended in moving water, coal, and refuse. The tests to prove this are adapted to the circumstances of running the station†—a matter, as most of us know, not always easy. Therefore their nature and number are to be subject to the approval of the engineer, so as not to clash with the conditions of statutory supply from the station. The tests of each unit estimated to have an output of 400 kilowatts, or of each group of units with an output of 1,200 kilowatts, are necessarily dependent on the circumstances of the load on the station. The alternating plant—both Brush and Thomson-Houston—was experimental at the time the contracts were made, therefore the first examples had to be under trial for six months. These trials had to be coincident with the supply, and dependent on the load on the station, and the contractors for that period were to be responsible for failure of all kinds. Under strict penalties, the contractors are answerable for the dimensions of foundations, flues, and chimneys, and are required to guarantee absence of vibration, noise, and smoke nuisance. As regards the boiler tests, under the usual conditions of temperature, external and at the base of the chimney, and state of barometer, and with coal having a calorific value of 13,500, it is obligatory that 77 per cent. of the heat is transferred to the water by the boilers and economisers together. As regards the consumption per horse-power of steam in the engines, the Brush Company have agreed to a limit with full load of 22lb. of steam exhausting to the atmosphere, and 18lb. when condensing. The Laing, Wharton, and Down Company have agreed to a limit of 20 and 17 respectively. For the commercial efficiency of the electrical 400-kilowatt generators, 80 per cent. when working at full load is prescribed, 2 per cent. of that only being allowed to be absorbed in the excitation. Besides, there was given a description of every test which each portion of the plant would be required to sustain. At the same time the widest latitude as regards design throughout the whole of the station plant and accessories is allowed.‡

I do not know if the meeting considers if any better way could be adopted for protecting the expenditure of capital and stimulating the energies of contractors, after it had been decided by others how much should be spent, how much should be the maximum output of the plant, and who were to be the contractors. What was probably one of the most difficult parts of the task was the description of the details of the adaptation of portions of the plant to sites and buildings still under design, so that no extras on the contracts should arise, and thus the equipment of the stations and sub-stations should be of the most complete and up-to-date description, and fully equal to the requirement of the capacity which the contractors had undertaken to provide. Both sites presented exceptional features, and the designing of the building structures for each differed entirely. That for the Wool Quay (since abandoned)§ required a building in which the floor of the basement would have been 20ft. below high-water mark, and the station plant should be placed on floors one above the other; the generators to be in the basement, the boilers over (on a Hobson's steel-girder floor), and the coal above.

The site at Meredith's Wharf, although the essential features of the first design have been retained, has been so enlarged that any description of it that might be attempted in this paper would not be sufficient.*

The estimate of the load factors of the public lighting of the City may be here made with some interest. Adopting Mr. Crompton's figure, which allows 25 per cent. for extra or reserve machinery, in the case of the public lighting the capacity of the plant is 890 - 222 = 668 kilowatts, or 5,851,680 kilowatts per annum. The 515 arc lamps represent 257,500 watt-hours, and the 906 incandescent lamps—half being 100 watts, and half 50—represent 67,950 watts more, or a total hourly consumption of 325·45 kilowatt-hours, which, with 4,030 running hours in the year, gives a load of 1,311,562 units per annum. But, in fact, the amount of the above plant that is spare or available for arc lighting in public buildings and elsewhere is very large, and it is better to regard the actual capacity of the plant exclusively devoted to public lighting, including reserve, as represented by 16 50 (500-watt) light machines, with an annual total capacity of 3,504,000 kilowatts. This will give a load factor of 37·4.

(To be continued.)

* Mr. Raworth and Prof. Kennedy, assisted by Mr. Wharton, represented the two contracting companies, while I represented the City of London Electric Lighting Company.

† The contractors could not provide means of running their large dynamos at their works. All real tests had to be made after delivery. This was an inherent difficulty for the engineer.

‡ The essence of these specifications was that, except in respect to a few points not within the scope of the contractors' work as electrical engineers, all details of design were left to them, subject to the final approval of the engineer.

§ This site had to be taken over by the City Company under the *concessionaire* contracts.

* The Institution will be better served if I leave it to the gentlemen who were selected by me as my assistants for that part of the work, and who have actually since carried it out—namely, Colonel Seddon (late R E.) and Mr. C. Thompson. The meeting will, I hope, understand that in refraining to give any detailed description of the equipment of the stations I am influenced by the wish that such should be undertaken either by the engineers of the respective contractors who designed and erected them, or by Mr. J. H. Jackson (one of my assistants), who is still superintending the same. As regards the building structures, I may, however, add that of three chimneys designed, and specified and contracted for under me, one—*i.e.*, that now to be seen close to Bankside—has been erected. There are features of its construction, especially with reference to the bond, that I should like to have time to describe. Its cost was £2,075, its height 150ft., and its internal diameter 12ft.

PHYSICAL SOCIETY.

The annual general meeting was held on the 9th inst., Prof. A. W. Rücker, F.R.S., president, in the chair.

The annual report of the council was read by the President.

Dr. Atkinson read the treasurer's report, and also an obituary notice of the late Prof. Tyndall.

The adoption of the report was moved by the President, and carried *nem. con.*

Dr. Chichester Bell and Mr. Griffiths were appointed scrutators, and subsequently declared the following gentlemen duly elected to form the new council.

President: Prof. A. W. Rücker, M.A., F.R.S. *Vice-Presidents*: Walter Baily, M.A.; Major-General E. R. Festing, R.E., F.R.S.; Prof. J. Perry, D.Sc., F.R.S.; Prof. S. P. Thompson, D.Sc., F.R.S. *Secretaries*: H. M. Elder, M.A., 50, City-road, E.C., and T. H. Blakesley, M.A., M.I.C.E., 3, Eliot-hill, Lewisham, S.E. *Treasurer*: Dr. E. Atkinson, Portesberg-hill, Camberley, Surrey. *Demonstrator*: C. Vernon Boys, F.R.S., Physical Laboratory, South Kensington. *Other Members of Council*: Shelford Bidwell, M.A., LL.B., F.R.S.; W. E. Sumpner, D.Sc.; Prof. G. Fuller; J. Swinburne; G. Johnstone Storey, M.A., F.R.S.; R. E. Baynes, M.A.: Prof. G. M. Minchin, M.A.; L. Fletcher, M.A., F.R.S.; Prof. O. Henrici, Ph.D., F.R.S.; Prof. S. Young, D.Sc., F.R.S.

Prof. Reinold proposed a hearty vote of thanks to the Lords of Committee of Council on Edueation for the use of the rooms and apparatus in the Royal College of Science. This was seconded by **Prof. J. V. Jones** and carried unanimously.

Votes of thanks were similarly accorded to the auditors, Mr. A. P. Trotter and Mr. R. Inwards, on the motion of **Mr. Watson**, seconded by **Prof. Fuller**, and to the officers of the society, on the motion of **Dr. Burton**, seconded by **Mr. Trotter**.

An ordinary science meeting was then held, when **Mr. Owen Glynne Jones, B.Sc.**, read a paper on "**The Viscosity of Liquids**," and exhibited the apparatus used in his experiments.

COMPANIES' MEETINGS.

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING COMPANY, LIMITED.

The seventh ordinary general meeting of the shareholders of this Company was held at 1, Great George-street, Westminster, yesterday (Thursday) afternoon, Mr. Granville R. Ryder occupying the chair.

The **Chairman**, in moving the adoption of the report, stated that it was very satisfactory, as it gave 1 per cent. extra dividend and offered good prospects. It was very pleasing to find that there had been an increase of one-third in the amount of

Digitized by Google

electricity supplied at an increase of only one-sixteenth in expense. With regard to the gross and net earnings, the latter showed a very favourable comparison with the former. So far only the fringe of the business in the districts had been touched, and there would be no fear of the limits having been reached. There were many private houses in the district which had not yet adopted electric lighting, and which would be sure to so later on, and residential flats were being erected which would prove safe customers. The time might come when they would have to reduce their prices for electricity, but he had no fear of that deleteriously affecting the Company, because a reduction in price would be followed by an increase of business. The capital account had been increased by nearly £20,000, which had been spent on the freehold of Kensington Court station, on machinery, mains, and meters, and on purchasing an area of supply from the Chelsea Company. The directors have written off as much as possible in justice to present shareholders.

Sir Frederick Bramwell seconded the adoption of the report.

Mr. J. F. Albright, who mentioned that the report stated that no provision had been made in the accounts for directors' remuneration, moved that they receive £500. This was seconded by **Mr. Killingworth Hedges** and carried.

Messrs. R. W. Wallace and Mr. A. S. Bolton were re-elected directors. Messrs. Lovelock, H. W. Whiffin, and Dickinson were reappointed auditors, their remuneration being increased from thirty to fifty guineas.

NEWCASTLE AND DISTRICT ELECTRIC LIGHTING COMPANY, LIMITED.

The seventh ordinary general meeting of this Company was held on Monday in Newcastle, Mr. J. D. Milburn (chairman) presiding.

The **Chairman**, in moving the adoption of the report and accounts (which were given in our last issue), said they had had a very great increase in the amount of work they were doing. They had had an increase of nearly 100,000 units of electrical energy during the year. That came partially from the North-Eastern Railway Company, at the station and other works, but also to a large extent from individual consumers. That must be looked upon as very satisfactory, because the more work they got to do, the more it consumed of their standing charges, and the more profit, up to a certain degree, it allowed them to make. They had been able to effect considerable economy in coal consumption. The drift to the river, and the condensing plant, introduced by Mr. Parsons, had been a very great success, notwithstanding that the cost had been greater than they anticipated. The difficulties of sinking and tunnelling down to the river were, of course, unknown quantities to begin with, and did not come out quite as they expected, and they had to spend a little more time and money in getting at it. They had got at it now, and it was answering their highest hopes in the direction of economy. They had considered the question of utilising town refuse as fuel. Some remarks were made about it at their last annual meeting, and it was found possible not only to do a good deal with the fuel, but also to set up a paper factory alongside the works. But Mr. Parsons, who had gone into the matter thoroughly, pointed out that, with duff coal at 3s. or 3s. 2d. per ton, very little economy could be got with anything of the kind. The fuel was all very well—it would burn, but it took a lot of labour to shovel it on to the fires; and if they could get their boilers singing away at full pressure with coal as low as 3s. 2d. per ton, they could hardly go into a question such as that. There was another matter which went into the question of cost. They would see in the gas company's report that the directors said that the policy of reducing the price to 1s 10d. per 1,000 cubic feet had not fulfilled the expectations they formed of it, and that they were going to put the price back again. It was calculated in electric lighting that 6d. per unit was equal to 5s. per 1,000ft. of gas. But the more they had opportunity and experience of knowing how the light was used, the more they were convinced that a great deal of waste took place in electric lighting. Now that the new lamps had come in, this had to a certain extent disappeared. He felt that they were approaching the day when the cost of the electric light would assimilate itself with that of gas. There was the question of the reduction of their own price. They did not feel quite yet that they could recommend it; they had had no complaints. Gradually their customers were waking up to the better use and idea of the economy of the electric light, and they hoped that that would popularise the idea of the light. They had said so much about the beauties of the one light as compared with the gross impurities of the other, that he did not think he need go into it again that day. But they wished their customers to know that less lamp power would give them a good enough light. They had recommended the same dividend as last year. Probably they might have done a little more, but they felt that they might some year have drawbacks, and they might have some bad luck; and it was only right that they should be prepared for that. The feeling of the directors was that they should not go backwards. If they got 6 per cent. this year, it would not be pleasant for the shareholders to go back to 5½ or 5 per cent. another year. They had applied to the local stock exchange for a quotation, and he would ask them to adopt certain alterations in the Company's rules, as required, with the result that very shortly the shares would be quoted in the local list, and anybody who wished to buy or sell shares would have every facility for doing so.

Sir B. C. Browne seconded the adoption of the report.

A **Shareholder** directed attention to the recent statement that the Corporation were thinking of obtaining the electric supply into their own hands. Would not that, he asked, mean serious competition with that Company?

The **Chairman** said they had heard nothing officially about that matter. The Corporation would have to agree with the Company as to a price for their undertaking, to buy them out. The Company, when seeking their provisional order, made a bargain with the Corporation as to limiting their dividend, and the Corporation would have very great difficulty in going to the Government to get an order themselves. Both the electric lighting companies would oppose them. The Corporation could not compel them to sell before the expiration of 30 years.

Councillor A. Fox, referring to the question of utilising the town refuse, said he believed the Corporation would be willing to pay 1s. per ton to have it removed.

The **Chairman** said the use of the refuse depended upon the amount of steam it evaporated. Mr. Parsons would no doubt be glad to consider any suggestion in the matter.

Mr. Parsons said it had been tried, and it was found that only a ton of water was evaporated per ton of refuse in most cases.

The report was adopted, and the alterations in the rules, rendered necessary to allow the shares to be quoted, were carried.

LIVERPOOL OVERHEAD RAILWAY COMPANY, LIMITED.

The eleventh ordinary half-yearly meeting of the shareholders of this Company was held in Liverpool on Tuesday, Sir W. B. Forwood presiding.

The **Chairman**, in proposing the adoption of the report, which was published in our issue of the 2nd inst., said that the report was of the first complete half-year of the Company down to December 31 last. The gross earnings for the six months amounted to £18,518. 4s. 7d., to which must be added £3,293 balance brought forward, making the total available sum £21,811. 11s. 2d. Deducting from this working expenses for the half-year £13,732. 11s. 2d., interest on debentures, and also interest on calls paid in advance, they had left over the sum of £5,452 available for dividend. Out of this the directors proposed to pay a dividend at the rate of 5 per cent. on the preference shares, and at the rate of 1 per cent. on the ordinary shares, which would leave a balance of £2,598. 7s. 1d. to be carried forward to the next half-year. The directors were well satisfied under all the circumstances with the result, for during the greater part of the half-year the trade of the port was most depressed, and the dock omnibuses obtained a considerable measure of support. The total number of passengers carried reached 2,475,639, or, roundly, at the rate of five millions per annum. The dock omnibuses are probably carrying at the rate of 2,500,000 per annum, so that they have a total traffic of about 7,500,000 against 2,300,000, the number carried by the dock 'buses before the railway was opened. Thus, during the first year of the railway's existence the dock traffic had increased threefold, which in itself was a most encouraging feature. Every day the regularity and convenience of this railway forced itself more and more upon the public attention and public support. The cost of working came out at over 72 per cent of the receipts, which looked large as compared with the experience on ordinary English railways, but this test was a fallacious one. If their fares were equal to those charged on ordinary English railways, their income would be very much larger, and the ratio of expenses greatly reduced. A better test is to compare their cost of working with the South London Electrical Railway. Their cost worked out 1s. 0½d. per mile, and the South London 1s. 0⅜d. per mile. They hoped still to make further economies. The extension to Seaforth would be opened in March. He had never wavered in his opinion that they had a good property. Mechanically it had been a great success, and financially it would also be a success.

Mr. R. Hobson, in seconding, expressed his sanguine feelings in regard to the future of the railway.

The report was then adopted.

The **Chairman** next proposed the payment of dividends at the rate of 5 per cent. per annum on preference shares, and 1 per cent. per annum on ordinary shares, less income tax, and that the balance on the net revenue account be carried forward. He hoped that this resolution was the forerunner of many of a still more gratifying character.

Mr. G. H. Robertson seconded the motion, which was carried. The re-election of directors and auditors closed the proceedings.

CENTRAL LONDON RAILWAY COMPANY.

A special general meeting of the Central London Railway Company was held last week at 30, St. Swithin's-lane, for the purpose of submitting to the proprietors a proposed Bill in Parliament, entitled "A Bill to extend the time for the purchase of lands for and for the completion of the Central London Railway and for other purposes."

Mr. F. A. Lucas, who presided, moved a formal resolution approving the Bill, this being seconded by **Mr. H. Smith**.

Mr. W. Morris (the solicitor) said the object of the Bill was to extend the time for the purchase of lands and the completion of works under the two Acts of the Central London Railway Company. The Bill now under consideration provided that the time for purchasing land in respect of the whole undertaking should be extended until 1897, and for completing the whole of the works until 1900. It had been suggested that, in consequence of a paragraph that by inadvertence appeared in a newspaper some time ago, he should state that there was nothing whatever in the Bill to alter the mode of traction intended to be adopted on the railway. The only traction authorised was electricity, and it was intended to adhere to that.

The Bill was approved.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS, LIMITED.

The thirtieth ordinary general meeting of the shareholders of this Company was held at Cannon-street Hotel yesterday (Thursday) to receive the report of the directors, which we printed in our last issue.

Mr. S. Wm. Silver (the chairman), in moving the adoption of the report and accounts, stated that at the last meeting he had held out favourable prospects. The colliery difficulties had, however, exercised some effect upon the working expenses; but their steamer which had been laying a cable on the West Coast of South America had brought back with her several hundred tons of coal which had been utilised at the works. For coal to be brought to England from South America, and thus employed, was rather a remarkable occurrence. The coal strike had also had the effect of stopping mills, and thereby reducing the quantity of material required for engineering purposes. They did not look upon general sales as a sheet anchor, for these had been a main means of support, as little had been done in cable work. They had, however, supplied the city of Brussels with the electric light. All this meant that more capital was required, the money being invested in work, stock, etc. The directors therefore recommended that a sum of £50,000 be added to the reserve fund. The stagnation of trade had enhanced competition and increased the difficulty of doing good business. There was plenty of business to be done, but it was difficult to find that which would be profitable. However, great care and caution had been exercised in this matter. The Chairman concluded by moving the adoption of the report.

Mr. Abraham Scott seconded this motion.

Mr. Lamont requested information respecting the reserve fund of £450,000, asking whether it could be dipped into in a bad year to pay debenture interest and something extra for ordinary shareholders, and whether it was invested in safe tangible securities at once realisable. Another **Shareholder**, referring to the item of £207,000 of debentures and shares held in other companies, did not think it advisable that one company should hold shares in another.

The **Chairman** explained that the reserve fund was capital employed, without interest, in lands, buildings, and machinery, and without this reserve there would be little to fall back upon as an industrial concern, and the result would be that instead of a dividend of 12½ per cent. there might only be 1½ per cent. The value of the reserve fund could be realised, and the item of £207,000 represented present value which could also be realised.

The **Chairman** moved the re-election, as directors, of Mr. Abraham Scott and Mr. Robert Henderson.

This was seconded by the **Hon. Henry Marsham** and adopted unanimously.

Mr. J. F. Clarke was reappointed auditor at a fee of 30 guineas.

Mr. Matthew Gray, the managing director, mentioned that he had visited Brussels and found that their work on the electric lighting of that city was very well done. He had also gone to their French works at Persan, which were in first-class order, and were fully employed. The Silvertown works were also fully employed.

CUBA SUBMARINE TELEGRAPH COMPANY.

The forty-fifth ordinary meeting of the Cuba Submarine Telegraph Company, Limited, was held on Wednesday at 58, Old Broad-street, under the presidency of Mr. Thomas Greenwood.

In moving the adoption of the report, the **Chairman** said the directors were pleased to be able to present so satisfactory a report. The depression in trade, which had so materially affected such a large number of industrial undertakings, had had some influence upon the receipts of the Company. Comparing the traffic receipts of the past half-year with those of the corresponding period of 1892, there appeared to be a reduction of £1,122. This was not due in any sense to the reduction of rates, which had not yet been made, but to the exigencies of trade. The net receipts for the half-year were only £787 less than in the corresponding period.

Mr. Charles W. Parish seconded the motion, which was carried unanimously. Dividends at the rate of 10 per cent. per annum on the preference shares and 8 per cent. on the ordinary were declared.

COMPANIES' REPORTS.

CITY OF LONDON ELECTRIC LIGHTING COMPANY, LIMITED.

Directors: Sir David L. Salomons, Bart., chairman; the Earl of Suffolk and Berkshire; the Hon. Alan Charteris; Joseph Bevan Braithwaite, jun.; Edward Lucas; Colonel B. H. Martindale, C.B.; Frederick W. Reynolds. David Cooke, engineer and manager. J. Cecil Bull, secretary.

Report of the directors to be presented to the shareholders at the ordinary general meeting of the Company to be held at Winchester House, Old Broad-street, E.C., on Thursday, February 22, 1894, at 2.30 p.m.

Capital.—The expenditure on capital account during the year ended December 31, 1893, amounted to £260,757. 18s. 1d. Details of this further outlay are given in the capital account, the whole of which is rapidly becoming revenue-earning. During the year the remainder of the preference shares have been issued, and all are now fully paid-up. An official quotation for the second issue of £200,000 has been applied for, and will no doubt be shortly granted. In order to provide for the additional expenditure which will be necessary to complete the undertaking, the directors propose to issue debenture stock from time to time as required. A first issue to the extent of £100,000 will be made immediately, and applications received from the holders of the ordinary and preference shares of the Company will be preferentially considered.

Revenue.

The gross revenue for the year was					£38,556	10 3
From which must be deducted the following items charged against revenue:						
Expenses of generation and distribution	£18,374	14	8			
Repairs and maintenance of plant, machinery, mains, lamp-posts, etc.	2,285	18	4			
	20,660	13	0			
Rents, rates, taxes, and general charges were	2,431	0	8			
					23,091	13 8
Leaving a net revenue of					15,464	16 7
To which must be added, other receipts					1,475	18 3
,, ,, ,, balance brought forward from 1892					434	6 7
Making a total of					£17,375	1 5

Of this sum £5,333. 6s. 8d. was distributed in July last in payment of an interim dividend on the first issue of £200,000 preference shares at the rate of 6 per cent. per annum for the half-year ended June 30, 1893, and the directors recommend a further dividend of 6s. per share on the first issue of £200,000 and of 3s. per share on the second issue of £200,000 preference shares, both payments being at the rate of 6 per cent. per annum for the half-year ended December 31, 1893. This will absorb £9,000, leaving a balance of £3,041. 14s. 9d., which the directors propose to carry forward to next account. After careful consideration, the directors have decided to establish two depreciation reserve funds, the first (Nos. 1 and 1A in the accounts) for the plant and running machinery, engines, boilers, dynamos, etc., and the second (No. 2 in the accounts) for the mains, meters, transformers, and other items from Nos. 2 to 10 in the capital account. For this purpose, out of the premium of £40,000 received from the second issue of preference shares, £30,000 has been set aside for the first fund and £9,152. 19s. 3d. for the second. Owing to the delay on the part of the local authority in giving its consent, as required by the Telegraph Act, 1892, to the use of certain tubes for telephonic purposes, the further steps necessary could not be proceeded with, and therefore it has not been possible to include in the accounts the sums payable by the New Telephone Company, Limited, under the agreement. Negotiations are, however, still proceeding, and it is hoped that the consent of the local authority will shortly be given. The working expenses for the year, including repairs and renewals, were 54·2 per cent. of the earnings. In view of the exceptionally fine and bright weather, which adversely affected the receipts, and the prolonged coal strike, which seriously increased the expenses, the directors consider this result satisfactory. The revenue shows a steady increase, the estimated rate at which it is now being earned being £64,000 per annum gross. This it is hoped will be largely increased as soon as the remaining transformer stations are at work. The directors were successful in obtaining an Act of Parliament amalgamating the three City districts into one for the purposes of the accounts and for defining in a clearer manner certain other matters in connection with the Company's provisional orders.

Lands and Buildings.—The greater portion of the main buildings is now practically finished and the remainder is expected to be completed in March next. The pumping station, switch-rooms, and engineer's offices are also in a forward state. Twenty-two transformer stations have been constructed, of which eight are in operation, and every effort is being made to have all the others ready for work during the current half-year. These 22 stations, when fully equipped, will be equal to supplying at least 400,000 8-c.p. lamps installed.

Generating Plant.—The plant already in position is of a capacity of 100,000 8-c.p. lamps, and further machinery is in course of construction by the contractors. The arc lighting plant has worked satisfactorily throughout the year. The total number of units sold was 1,741,099.

Street Work.—This work is now approaching completion. On the 1st February, 1894, 580 miles of "ways" had been laid in the City in 55½ miles of streets, into which 105 miles of cables have been drawn. Sufficient "ways" have been laid down to supply a demand of 400,000 8-c.p lamps installed. Conduits have been laid in all the compulsory streets in the Southwark district.

Private Lighting.—Nearly 1,300 private consumers, representing a total of 72,000 8-c.p. lamps, are being supplied with current from eight transformer stations, and during the current half-year it is expected that the whole 22 stations required for the entire City will be at work. Applications continue to come in satisfactorily, the total received to date being equal to the supply of current for 100,000 8 c.p. lamps.

Public Lighting.—The lighting of the main thoroughfares of the City with arc lamps was virtually completed early last year, only a few lamps for which positions have not been assigned remaining to be fixed, but the Commissioners of Sewers have not yet given

Digitized by Google

the order for the lighting of the lesser streets with incandescent lamps. The Company is prepared to carry out the lighting of these streets immediately upon receipt of the order to proceed, the necessary plant for this purpose being already in position.

Directors.—In accordance with the articles of association, two of the directors, Sir David L. Salomons, Baronet, and the Hon. Alan Charteris, retire. Sir David L. Salomons, being eligible, offers himself for re-election, but Mr. Charteris, owing to continued ill-health, resigns his seat. The directors do not recommend that any steps be taken at present to fill the vacancy thus created.

Auditors—Messrs. W. H. Pannell and Co. retire, and, being eligible, offer themselves for re-election.

Dr. CAPITAL ACCOUNT AT DEC. 31, 1893.

Expenditure.	Public lighting. £ s. d.	Private lighting. £ s. d.
Machinery and plant: boilers, pumping, feed-heating appliances, engines, arc dynamos, alternators, and exciters	32,196 13 4	145,452 10 0

WESTMINSTER ELECTRIC SUPPLY CORPORATION, LIMITED.

Directors: The Right Hon. Lord Suffield, K.C.B.; Edmund Boulnois, Esq., M.P.; W. Hayes Fisher, Esq., M.P.; Sir Douglas Galton, K.C.B., F.R.S.; J. Browne Martin, Esq.; James Heslop Powell, Esq.; R. W. Wallace, Esq. General manager: Captain Edmund I. Bax. Engineer-in-chief: Prof. Alex. B. W. Kennedy, F.R.S., M.I.C.E. Secretary: Frank Iago, Esq.

Report of the directors to be presented to the shareholders at the ordinary general meeting to be held at the offices of the Corporation, Eccleston-place, S.W., on Wednesday, February 21, 1894, at 11 a.m.

The Board of Directors, in presenting their report and accounts for the year 1893, are pleased to state that the business of the Corporation continues to make steady and satisfactory progress. The directors have again thought it desirable to reduce the price of current from 7d. to 6d. per unit, and this change came into effect on April 1 last. The supply of current which on December 31, 1892, was being provided for an equivalent of 98,686 lamps of 8 c.p., had increased by December 31, 1893, to the equivalent of 131,565, and at the present time there are on circuit the equivalent of 134,268 lamps of 8 c.p., and applications have been received for a further 9,451. The length of roadway along which mains have been laid now exceeds 35 miles, making about 140 miles of ways, into which upwards of 106 miles of copper (strip and cable) have been drawn. The plant and machinery have been working satisfactorily throughout the year, and have been fully maintained from revenue. In the manufacture and distribution of electricity and in the general expenses a considerable reduction has been effected in the cost per unit. Since the last meeting, owing to the rapid increase in the Corporation's business, the directors found it necessary to issue the balance of £30,000 4½ per cent. mortgage debentures. The issue having been largely over subscribed by the shareholders, the directors regretted they were unable to allot in full. The net revenue of the year amounts to £12,830, out of which £4,370 in payment of an interim dividend at the rate of 3 per cent. per annum for the half-year ending June 30, 1893, has already been distributed. The accounts now show a balance of £8,460 to the credit of net revenue, from which the Board recommend the payment of a dividend at the rate of 5 per cent. per annum for the half-year ending December 31 last, carrying forward a sum of £1,190. In accordance with the articles of association, two of the directors, Lord Suffield and Mr. Hayes Fisher, retire, but being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Bros., also retire.

Revenue Account, Year ending Dec. 31, 1893.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—The receipts for the week ended February 9 were £3,007.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 11th inst. amounted to £691.

Aluminium Company.—An extraordinary general meeting of the Aluminium Company, Limited, was held on Wednesday at the Cannon street Hotel, E.C., to alter article of association 92.

Margam.—The Lighting Committee of the Local Board have recommended that the district should be lit by electricity, and that a report be obtained from Messrs. Drake and Gorham on the matter.

Babcock and Wilcox Company.—An interim dividend has been declared for the six months ending December 31, 1893, at the rates per annum of 6 per cent. on preference shares and 10 per cent. on ordinary shares.

Tender Accepted.—The tender of Messrs. S. J. Waring and Sons, at £320, has been accepted for electric wiring and ventilation at the Hamilton Café, Chapel-street, Liverpool, for the Clerks' Café Company, Limited.

Digitized by Google

Abergavenny.—The Improvement Committee have resolved that the Gas Committee be empowered to call in the services of an expert in the matter of lighting Abergavenny by electricity.

Mosley and Co., Limited.—This Company has been registered with a capital of £11,000 in £1 shares to acquire patents relating to the deposition by electricity of zinc upon steel, iron, or other metals, and to develop the same.

Bradford.—On the electricity works the Corporation have made a profit of £1,179 during the past half-year, as against £1,089 for the previous half-year, despite the fact that they had had to pay £600 extra on account of the coal strike.

Brush Electrical Engineering Company.—The transfer books of the Brush Electrical Engineering Company, Limited, will be closed, both for debenture stock and preference and ordinary shares, from February 20 to March 5 inclusive.

Horsell (Surrey).—The tender of Mr. H. Ingram has been accepted for the erection of a bungalow in the parish of Horsell, for Mr. J. B. S. Lancaster, to be heated entirely with gas, and lighted by electricity. Mr. R. Clamp, A.R.I.B.A., Woking, is the architect.

Liverpool.—The Watch Committee of the Liverpool Corporation have received a letter from Mr. Davies calling attention to his system for the utilisation of tidal power for electric lighting purposes. The letter was referred to the electric lighting company.

Appointments Vacant.—As mentioned in our last issue, the Blackpool Corporation require a resident working electrical engineer for the tramways. The Corporation of Edinburgh invite applications for the post of resident engineer for central electric lighting station.

Leamington.—Through the kindness of a member of the congregation in advancing the amount of the initial cost, the electric light is now installed at the parish church. Nearly 300 lamps have been fixed. From the central dome depends a large and ornamental electrolier.

Newcastle.—A special committee of the Town Council relative to the Corporation undertaking the provision of electricity, has been held. It was decided to communicate with other towns where the corporations have sole charge of the electric lighting, and obtain particulars regarding the same.

Sutton.—It was reported at a meeting last week of the Local Board that the proposed deed of transfer regarding the electric light had been revised by the clerk, so as to include the latest suggestions of the Board of Trade. The draft was referred back to the committee for further consideration.

City and South London Railway.—The receipts of the Company for the week ending February 11 were £937, against £952 for the same period last year, or a decrease of £15. The total receipts for the first half-year of 1894 show a decrease of £135 compared with those for the corresponding period of 1893.

Oswestry.—Mr. Lloyd mentioned at a meeting of the Town Council last week that he would be glad if they could come to some terms with the electric lighting company. The company had informed them that they were ready to commence operations, and it was their duty to see that the town was well lighted.

Limehouse.—At a meeting of the District Board of Works last week, Mr. Beverley enquired if the special committee appointed to consider the proposed lighting of the district by electricity intended to report to the Board. In reply, Mr. Mills explained that the report had been drafted, but that its presentation was delayed.

Appointment.—Mr. Le Gros Horne, of the Electric Light Department, General Post Office, has been appointed to the post of Superintendent of Telegraphs and Electric Light to the Great North of Scotland Railway Company. The electric light is a new post added to that of the telegraph work, and extensive additions of plant will be made.

Burton.—At a meeting of the Town Council last week, Alderman Lowe announced that supply of the electric light would be ready during the present month. He stated that if the Corporation did not receive a great many more applications for its use—they had only had 20—they would lose considerably over the introduction of the new illuminant.

Portsmouth.—The Electric Light Committee of the Town Council last week submitted certificates from Messrs. Waller and Manville for payment to the contractor for buildings of £225, to the contractors for boilers, engines, and electrical plant £1,609, and to the contractors for conduits, etc., £1,840, and recommended that such amounts be paid. The report was adopted.

Paisley.—The Cartvale Chemical Company at the beginning of the winter decided to adopt the electric light, and entrusted to Messrs. Robertson and Co., electrical engineers, 9, Old Sneddon, the work of installation. This is now completed, and the works are lighted with seven arc lamps of 2,000 c.p. A 12-h.p. steam-engine drives a Woodside dynamo, which supplies the lamps.

Bridgend (Glamorganshire).—The Local Board are prepared to receive tenders for the transfer of the provisional order for electric lighting obtained by the Board in June, 1893, on the basis of the payment to the Board of the costs of and incidental to the obtaining of the order, and which amount to about £250. Further particulars may be had of Mr. T. J. Hughes, solicitor, clerk to the Board.

Swansea.—The Executive Committee of the Harbour Trust have had under consideration a report by the general superintendent upon the subject of the electric light wires, and they recommended that certain bare wires should be replaced by insulated wires, and accordingly that they be authorised to invite tenders for and arrange to carry out the work. The recommendation has been adopted.

Ballymena (Ireland).—As stated in our last issue, tenders are invited by the 3rd proximo for lighting the town either by gas or electricity, from August 16, 1894, until May 16, 1895, for the Town Commissioners. Plans, time-table, and specification to be seen at the office of Mr. Henry O'Hara, town clerk, Town Hall-chambers, Ballymena. Sealed tenders to be lodged with the town clerk by the date mentioned.

Radcliffe.—Mr. Bennett and Mr. Preece have met the Electric Lighting Committee to confer with them as to the preparation of the report of the proposed electric lighting of the district. Each has been instructed to prepare a report upon the most advisable method of producing and distributing electricity within the limits of the district, giving estimates of the cost of production and maintenance by both Dowson gas and steam.

Belfast.—The report of the Harbour Commissioners for 1893 contains the following: "A contract for the execution of certain works in connection with the lighting by electricity of the Queen's Quay and Abercorn Basin was entrusted to Messrs. Siemens Bros. and Co., Limited, who supplied the engine and boiler (which were manufactured by Messrs. Combe, Barbour, and Combe, Limited), and the electrical plant, comprising two dynamos and 30 arc lamps, with all requisite pillars and cables. The foregoing works were carried out under the supervision of Mr. George Combe, electrical engineer, of this city."

Electric Lighting in Stirling.—The Board of Trade have sustained an objection to the decision of the Stirling Town Council refusing to consent to the application of the Caledonian Electric Supply Company for a provisional order for Stirling, in respect that the statutory 30 days' notice was not given of the Council's intention to apply for a provisional order themselves. The effect of this ruling is to render it necessary to begin the proceedings again, and notices are to be issued of a special meeting of the Town Council in March for the purpose of determining whether the Corporation shall apply for a provisional order.

Accrington.—The Watch and Cemetery Committee of the Town Council have considered tenders for putting in an installation of electric bells to each fireman's house from the fire brigade station. The tenders varied in amount from £48. 6s. to £85. It was resolved that the chairman and town clerk make enquiries as to the character of similar work done by the firm submitting the lowest tender, and report to the next meeting. The Legal and Parliamentary Committee have considered the question of pushing forward with the electric light installation, and have instructed the Mayor, Alderman Moorby, and Councillor Eli Higham, with the surveyor, to visit the electric lighting works at Morecambe and report thereon.

Blackpool.—At a meeting of the Town Council last week, Mr. Councillor Bickerstaffe asked for an explanation of certain transactions with Messrs. John Fowler and Co., in regard to the tramways. Mr. Councillor Pearson said that at the outset it was decided to procure two new engines to drive the electric tramways, and arrangements were made with Messrs. John Fowler and Co. whereby they should take over the two old ones and erect new engines for the sum of £120. They had since received reports from their advisers that with very few alterations the engines would do the work, and they were now endeavouring to get Messrs. Fowler and Co. to release them from their reliability in regard to these engines.

Darwen.—The Corporation of Darwen have accepted the tender of Mr. Thomas Barton, the Electrical Works, Blackburn, for a complete generating and distributing electrical plant, to be utilised at present for the new technical schools, but which is intended to form a nucleus for the lighting of the town. The plant consists of dynamos and switch and distributing boards, made by Mr. Barton; installation cables, manufactured by Messrs. Siemens Bros. and Co.; storage cells, made by the Electrical Power Storage Company; and gas-engine, by Messrs. J. E. H. Andrew and Co. The plant has been erected upon the same lines as that in the Blackburn technical schools and other public institutions carried out by Mr. Barton.

Lighting of Chelmsford.—A meeting of the Town Council was held last week to consider Messrs. Crompton and Co.'s application to the Board of Trade for a provisional order to supply electric energy for the public and private lighting of Chelmsford. The Mayor urged that they should settle the whole question that evening. Councillor Britton moved that the minute passed by the Council on December 27 be rescinded as far as it related to Clause 80 of the provisional order, and that they should accept the terms of the provisional order as modified by the solicitors for the company. Councillor Maskell seconded the motion, which, after some discussion, was carried. A further resolution, that the consent of the Council be given to the amended provisional order, was also adopted.

Lighting of Halifax.—The following tenders for the supply of electric lighting plant have been accepted by the Halifax Corporation: Messrs. Pollitt and Wigzell, Sowerby Bridge, three non-condensing steam-engines, £1,860; Messrs. Yates and Thorn, Blackburn, three steel Lancashire boilers, £1,688, also fuel economiser, with brickwork, £489; Electric Construction Company, Limited, Wolverhampton, alternators, £1,785, and exciters, £270; Messrs. John Fowler and Co., Leeds, switchboard, £460; Messrs. C. A. Parsons and Co., Newcastle, transformers, £844. 6s.; Messrs. Siemens Bros. and Co, Limited, Westminster, supplying and laying underground cables, etc., £7,450; Mr. Thomas Mitchell, of Warley, for masons' work, £5,200. 6s. 8d.; and Mr. James

Digitized by Google

Mackrell, of Elland, wrought-iron work, £841, work required in the erection of the central electric lighting station.

Dover.—The minutes of the Electric Light Sub-Committee, read at a meeting of the Town Council last week, stated that the installation of the Town Hall had been under consideration, and that plans and estimates had been received from the Dover Electricity Company, and Mr. Chappel consulted as to the lights. The estimates were—for the new Town Hall, wires £308, fittings £264. 12s., total £572. 12s ; Maison Dieu Hall, wires £180, fittings £150, total £330. The committee recommended that the tender for the Connaught Hall only should be approved. Alderman Pepper, in moving the adoption of the report, said that the estimates were higher than expected. He moved that the committee's recommendations be accepted, and Councillor Barnes seconded the motion, which, after some discussion, was adopted.

York.—The question of electric light expenses at the Courts of Justice was referred to last week by Mr. Walker, who said that there was an item of £19. 10s. 7d. for lamps for electric light for one quarter at the Courts of Justice. Was that for repairs, breakages, or what? He also noticed that the gas used for the gas-engine to produce electricity for the September quarter was £27. 4s. 8d., whilst the wages for working the gas-engine amounted to £33. 4s. for one quarter, the items amounting altogether to about £75. They had, therefore, a right to assume that the gas accounts for the quarters of March and December, when the days were longest, would be about double. He estimated that the electric light for the Courts of Justice would cost them for gas, engine, and man, exclusive of other charges, something like £270 or £280 per year. Alderman Milward said that he had better have notice of the question.

Lighting of the Victoria-embankment.—The Highways Committee of the London County Council on Tuesday reported that the drawings for the installation works for the lighting of the Victoria-embankment and gardens, and Westminster and Waterloo Bridges, are in course of preparation, and will shortly be so far completed that the specification and estimates may be prepared. In the meantime it appeared to them that the work of laying the necessary conduits and forming the refuges round the lamp columns could be proceeded with at once. The chief engineer's estimate of the cost of this preliminary work is £2,100, and the committee recommended that, subject to an estimate being submitted to the Council by the Finance Committee, as required by the statute, the work of laying the necessary conduits and the forming of the refuges round the lamp columns in connection with the electric light installation for the Victoria-embankment, etc., be carried out by the Council without the intervention of a contractor; and that the plans, specification, and estimate be referred to the Works Committee for that purpose. This matter was referred back to the committee.

Lighting at Colchester.—The Lighting Committee of the Town Council reported last week that they had considered the steps to be taken for carrying out the provisions of the Colchester electric lighting order, which was confirmed by Parliament on June 9, 1893. The committee concluded that it would be better, in the first instance, to have a preliminary interview with an electrical engineer, and decided to invite Mr. W. H. Massey to meet them. Mr. Massey attended a meeting of the committee on January 29, when the whole question was fully discussed, and his opinion invited on various points. Mr. Massey stated, having in view the fact that the electric lighting works would probably be carried on in conjunction with other undertakings of the Corporation, and the low rate of interest at which the authority could borrow, the Council would be able to undertake the supply of electricity, and make the undertaking pay its way. Several sites which the committee considered might be suitable for the purposes of a lighting station were inspected. The committee had instructed Mr. Massey to report fully upon the points above mentioned. The report was adopted.

Tenders Required for Islington.—As will be seen from our advertisement columns, the Vestry of the Parish of St. Mary, Islington, invite tenders for supplying and erecting plant and machinery for the supply of electricity, and for supplying the conduits and mains, which will be laid by the Vestry. The specification is divided into the following sections: (1) boilers (Lancashire), steam and exhaust pipes, pumps and injectors, feed-water heaters; (2) boilers (water-tube); (3) horizontal engines for driving alternators; (4) engines for driving arc lighting dynamos; (5) alternators and exciters; (6) main switchboards and instruments; (7) continuous-current series dynamo, with instruments, arc lamps, and lamp-posts; (8) testing and other instruments; (9) conduits, street boxes, etc.; (10) single and concentric mains. Contractors may tender for the whole or any one or more sections. Application may be made for the specification, general conditions, and form of tender to Mr. Albert Gay, electrical engineer, Vestry Hall, Upper-street, Islington, on and after the 19th inst. A charge of £1. 1s. per section will be made for plans and specifications, but this sum will be returned on receipt of a bona fide tender. Sealed tenders to be addressed to Mr. Wm. F. Dewey, vestry clerk, at the Vestry Hall, Upper-street, and delivered not later than March 21.

The Northern Society of Electrical Engineers.—The following candidates were recommended on the 9th inst. by the council to be balloted for as members: Francis G. Bailey, M.A., University College, Liverpool; William Banks, 32, Corporation-street, Bolton; Alfred Bellamy, J. E. H. Andrew and Co., Reddish; John C. Chambers, P.O. Telegraphs, Leeds; F. Morris Chapman, General Electric Company, Salford; H. J. Coates, General Electric Company, Salford; James Connolly, Connolly Bros., Blackley; John T. Connolly, Connolly Bros., Blackley; R. C. Douglas, Manningham, Bradford; Chris. Elliott, National Telephone Company, Bolton; A. E. Garbutt, Fowler-Waring Cables Company, Newcastle; Robert Hammond, 117, Bishopsgate-street, London; H. W. Heywood, 12, Brazenose-street, Manchester; H. Hirst, General Electric Company, London; Herbert Lindley, Browett and Lindley, Patricroft; Alfred Magnall, National Telephone Company, Warrington; Robert Matthews, Parr's House, Heaton Mersey; E. Alexander Paris, West Norwood, London; John B. Parkinson, York-street, Manchester; Ernest Prestwich, F. H. Royce and Co., Manchester; Percy A. Ramage, Mather and Platt, Manchester; Jos. F. Simpson, 3, Hammerton-street, Burnley; Robt. Taylor, W. T. Glover and Co., Salford; A. Lester Taylor, 36, Dale-street, Liverpool; Arthur P. Wood, Mather and Platt, Manchester; E. H. Nisbett, British Insulated Wire Company, Prescot.

Oriental Telephone and Electric Company.—The directors have issued a circular to the shareholders in which they state that ever since the present Board took office it has been its desire to effect an amalgamation of the two classes of shares, so that there might be one class of shares only, and that dividend-bearing and free from all liability. The litigation in which the Company has been involved was brought about during the endeavours to come to an arrangement with the holders of vendors' shares on the above lines, and arose through a question raised as to the legal interpretation of the agreements between the vendors and the Company in connection with the payment of dividends. Since the decision in the House of Lords, adverse to the interests of the holders of vendors' shares, negotiations have again been opened with the Board by some of the largest holders of these shares, resulting in a committee of the Board meeting the above shareholders. After protracted sittings a provisional agreement has been come to, proposing that there shall be one class of shares of £1 each fully paid-up; that the ordinary shareholders shall receive one such share for every two shares of 11s. paid; that the holder of fully-paid shares shall receive the above shares at the rate of 18 for every 20 now held by him, and the holders of vendors' shares shall receive such shares in the proportion of 15½ for every 20 shares now held by them. The paid-up capital will thus be reduced to £171,497, in place of £199,746; the ordinary shareholders will be relieved from all liability as to calls, and the holders of vendors' shares will come in for immediate dividend. All arrears due to the ordinary shares to be cancelled, and the Company to pay the cost of the recent litigation. The holder of fully paid up shares, and the holders of nearly all of the vendors' shares have agreed to the scheme. A special meeting has been convened for 21st inst., at which resolutions for placing the Company into voluntary liquidation will be proposed. It is hoped that the reconstruction will be carried through before the approaching annual meeting, when a dividend for the past year will be declared.

Claim Over a Contract.—At the Worcestershire Assizes last week, before Lord Chief Justice Coleridge, the New British Electric Light Installation Company, Worcester, brought an action against Mr. E. Bremner Smith, electrical engineer, Oswestry, and Mr. Charles Fitzroy Somerset, Trederwen, Montgomeryshire, to recover £153, balance of amount due for work done. Mr. Vachell appeared for the plaintiff company, Mr. Spearman for Smith, and Mr. Lawrence for Somerset. It appeared from the opening statement of Mr. Vachell that there was practically no dispute as to the amount of the claim. The question was as to who was to pay the costs. The plaintiff company had been compelled to join the two defendants in the action, as each claimed that the other was liable, and the company did not want to have to pay the costs. The defendant Smith applied in April, 1882, for an approximate estimate and suggestions for electrical work for a client of his, and after the specifications had been sent by the plaintiffs, it was revealed that the client was the defendant Somerset, who had a mansion in Montgomeryshire. After the work had proceeded some time, Smith sent to Somerset a certificate for £100 on account, and Somerset drew a cheque for the amount and sent it to Smith, who forwarded it to the plaintiffs. A final instalment became due, and again Smith made out a certificate for £153, the amount now sued for. When payment was applied for Somerset repudiated any contract with the company, and said his contract was with Smith. Smith declined to pay, as he was only the agent of Somerset. After the dispute arose, Smith amended his certificate for £153. 6s. to £137. 15s. 4d., and that amount the plaintiffs were willing to accept. Mr. Lawrence said that Somerset contracted with Smith, and had paid to him the whole amount due in respect of that work. He had paid £230. 10s. and £16. 10s. to other persons and discharged the whole liability. Somerset had nothing to do with the plaintiff company. Therefore, having paid to Smith all he owed, it was not fair to ask him to pay the costs. Mr. Spearman contended that Smith was the agent of Somerset in that and various other works. Somerset did not pay the £130. 10s. 2d. on the second certificate until after action had been taken and Smith had made every effort to get the money. The learned Judge gave judgment for plaintiffs for the £137. 18s. 4d. agreed upon, and ordered Smith to pay the costs of the plaintiffs and of the defendant Somerset. His Lordship said it was quite clear to him that plaintiffs were the sub-contractors of Smith, and that Somerset had nothing to do with the plaintiffs, and was brought into the action by the defendant Smith.

The Lighting Question at Harrogate.—A public meeting, convened by the Mayor (Alderman Fortune), in compliance with a requisition, was held last week "for the purpose of taking into consideration the electric lighting question, and determining as to the expediency of the Corporation undertaking the installation or supply of the electric light at this crisis, now that the public burdens are likely to be much increased." The Mayor presided,

Digitized by Google

Mr. Samson Fox moved the following resolution: "That this meeting of ratepayers of the borough of Harrogate does not agree with the Corporation entering into any scheme of electric lighting at the town's expense. and hereby desires them to reconsider the question with the view of transmitting their rights to an independent and private company." The meeting, he said, had been convened by a number of gentlemen who were of opinion that the movement which had taken place in the Council had not been one that was conducive to the best interests of the town from a financial point of view. They were met to ask the Council to reconsider their decision. It was his greatest desire that the town should be lighted by electricity. They did not oppose the introduction of the electric light, but the manner in which the Corporation proposed to go about it. The electric light should be brought within the reach of the poorest cottager. It would be a dangerous thing for the Corporation to take upon itself what so few other corporations had done. Out of a list of 25 towns whose affairs he had investigated, no fewer than 19 had let the electric light undertaking to private companies. This was an example Harrogate would do well to imitate. Alluding to the various other purchases made by the Corporation, which had raised the total of their indebtedness from £110,000, at which it stood two years ags, without the proposed electric scheme, to £220,000, Mr. Fox, while quite admitting that this expenditure had been perfectly justifiable and necessary, urged the Corporation to hesitate before plunging into further debt. The better plan was to let a private company, with its own money and experience, accept the risk of the venture. Mr. M. Harrold seconded the resolution. Councillor Chippendale supported the action of the local authorities. Electricity, he said, unlike gas, fulfilled all the conditions required by health. It would be a very expensive matter to have a company introducing the light into Harrogate. As to the 25 towns mentioned by Mr. Fox, he could mention 25 others, only four of which let out their lighting to private companies. He would candidly admit that the scheme might not pay at first, but it was his belief that it very soon would do so. Councillor D. S. Ward also spoke in favour of the action of the Corporation. Mr. G. Whitehead moved an amendment that the progress made in electric lighting in a number of other towns and cities in England and abroad justifies the action of the Harrogate Town Council in taking and developing electric lighting in the borough, in addition to keeping and protecting all the public rights obtained in the provisions secured to them by Parliament. He mentioned various important towns which had controlled their own lighting, and made good profits thereby. If the profits made by the local gas and waterworks companies had accrued to the Corporation, they would have reduced the rates one-half. Mr. Johnson seconded the amendment. Eventually the resolution was carried by a majority. At the quarterly meeting of the Town Council on Monday, Mr. Meyer moved, in view of the recent town's meeting, to rescind the resolution "That the Council will itself carry out the electric lighting order." Alderman Milner seconded the motion, which was rejected. After discussion the original minute to accept the tender of the British Wire Company for cables, subject to the consent of the Local Government Board, was confirmed by 13 votes to 8.

Lighting of Stafford. — The clerk to the Town Council mentioned last week that the Local Government Board would be prepared to sanction the proposed loan of £20,000 for the purpose of electric lighting, and to give their consent under Article 7 of the Stafford Electric Lighting Order, 1890, to the appropriation of certain land at the gasworks to such purposes on being furnished with a tracing showing by different colours the land proposed to be so appropriated, and also the portion proposed to be purchased for the same purpose at a cost of £500. The Board wished at the same to be informed whether a provisional agreement had now been entered into for the acquisition of the land which was to be purchased. The Electric Lighting Committee reported at the same meeting that the engineer, Mr. Bell, had had several interviews with Dr. Hopkinson, and that the necessary plans, drawings, and specifications were ready for obtaining tenders for buildings, engines, boilers, dynamos, etc. The committee recommended that the portion of land shown on the plan submitted, containing 1,224 square yards, now forming part of the gasworks site and not required for gasworks purposes, should be acquired by the Council for electric lighting purposes at a cost of £125. The committee further recommended that the town clerk should be instructed to prepare the necessary documents and also an agreement with Messrs. Bostock as to easement for laying pipes and cables along their private road. Mr. Bell had been instructed to engage a quantity surveyor at a remuneration not to exceed 1¼ per cent., exclusive of cost of lithographing. The report also contained a recommendation that tenders be obtained for electric lighting machinery and other necessary works. Alderman W. H. Peach proposed the adoption of the report. He observed that very considerable progress had been made since the last report towards carrying out the powers of the Council by the provisional order of 1890, inasmuch as the sanction of the Local Government Board had been obtained and drawings of the proposed new central electric supply station were now submitted. The committee confirmed their previous recommendation that the best and most suitable site for the new works which could possibly be obtained was the land adjoining the gasworks, and, in order to allow ample room for future extensions, it was necessary for the Corporation to purchase land and make arrangements as mentioned in the report. The object in obtaining this land was to facilitate the extension of works when required. The new works had been so designed that the whole building could be duplicated without alteration or demolition. The buildings would consist of a large engine and dynamo house 40ft. wide and 82ft. long, sufficient room being allowed for the reception of three 100-h.p. engines and two 200-h.p. engines, with dynamos, when necessary. The boiler-house would be 41ft. wide and 56ft. long, with chimney measuring 7ft. at the base and 120ft. high. Three steam-boilers of the Lancashire type, to work at a pressure of 125lb., would be put in, and these would supply the gasworks with steam in addition to the electricity works. Room would be allowed for a fourth boiler to be added at any future time. Facing Messrs. Bostock's factory would be erected a two-storey building, 73ft. long and 17ft. wide, which would contain accumulator-room, workshops, offices, etc., on the ground floor, the upper floor being reserved for stores, showroom, and for testing purposes. The buildings would be constructed of red pressed bricks, with blue and stone mouldings, and the dynamo-room would be lined with glazed bricks. Dr. Hopkinson had recommended that three horizontal compound high-pressure steam-engines should be put down, each capable of giving at least 100 h.p., and everything would be arranged so that two additional engines could be added, each of 200 h.p. He also recommended that three dynamos should be put down, each to be driven by belting from engine flywheels. These dynamos would be continuous-current machines, each capable of giving 300 amperes at 220 volts when the dynamos were running at about 600 revolutions per minute. A battery of accumulators would also be put down, containing 112 cells, which would supply the light day loads and the supply after midnight, so that at first only one, or at most two, gangs of men need be employed during the day and evening. The capacity of the station would be such that 5,000 16-c.p. lamps could be wired before extensions were required, and if a revenue of only 12s. per lamp wired per annum were obtained, this would mean an income of £3,000, which would pay for the working expenses, interest on a capital of £15,000, redemption of the same in 30 years, and leave a margin of profit in reduction of rates. The capital required could be borrowed at 3½ per cent. interest and repaid in equal annual instalments of principal and interest during 30 years, which meant an annual payment of £790. The estimated working expenses, including repairs and maintenance, came to £1,250, making a total of £2,140. The committee had very great hopes of making the scheme pay, and had every reason to believe that they would make a profit out of the concern in a couple of years. Alderman Silvester seconded the adoption of the report, which was carried.

Lighting of Monmouth.—A letter was read last week at a meeting of the Town Council in reference to the application of the Town Council for sanction to borrow £18,000 for works of sewerage and sewage disposal and for purposes of electric lighting. The Local Government Board pointed out that as the Town Council have not yet obtained a license or provisional order in respect of their scheme of electric lighting, the Board will be unable to consider this part of the application until such license or order has been obtained. Continuing, the letter stated: "The Board are of opinion, however, that the question of the sewerage and disposal of the sewage of the borough should not be delayed on this account, but should be dealt with at once. Further, they are advised that the pumping of the sewage by turbines as proposed in the original scheme is not likely to be attended with any advantage, and that when looked at apart from electric lighting this scheme cannot be regarded as a good one; and that the Board therefore considers that the Town Council should either modify the present scheme, or select one of the schemes submitted in answer to their advertisement, and apply for the Board's approval thereof as soon as possible." The Mayor remarked that this letter did not mention the amended scheme which Mr. Lailey submitted on December 16, and on the receipt of the letter, therefore, he wrote to the Local Government Board, drawing attention to the amended scheme. The reply received was to the effect that the Local Government Board's letter of January 17 was written after full consideration of the modified scheme sent by Mr. Lailey. The Mayor remarked that these letters opened up a very serious matter. The letters were not of the satisfactory nature he could have wished. At the same time he saw nothing to induce him to alter the opinions he had held up to the present time, and he was of opinion still, that it was only to the ultimately combined schemes that they could reasonably look for relief in the heavy expenses they were to undertake in respect to the drainage. And if they could not get this project accepted as a combined scheme—which after these letters he saw no chance of doing—the next best thing was to try and get it through in two halves, and he should himself suggest that they should postpone, for the time being, the electrical portion of it until such time as they were in possession of the order. They could reintroduce the matter and confine their attention to the sewerage portion of the work, but upon lines that would ultimately dovetail in with the electrical portion. With this object in view, the proposal made by Alderman Vizard at their last meeting would come in as the very thing they wanted. The Local Government Board did not condemn their scheme, but, looked at apart from the electric lighting, they said they did not consider it would be a good one. And the same opinion had been expressed all along. If they had to do their purification by steam, they would be landed into an expense of £100 or £200 per year, and if they could not utilise water for the electric lighting, the expenses would be quite £300 a year over and above the amount of the water estimate. It was undoubtedly to the water scheme that the Local Government Board objected, and they had based their objection upon the report made by the inspector. The same remark would apply to the site for the pumping works. That was the only site in which they could employ water, and in view of the ultimate joining of the two halves of the scheme they must cling to this site. To remove this uncertainty as to whether the water would act or not, Mr.

Digitized by Google

Vizard's motion came in. The town clerk, in accordance with instructions given at the last meeting of the Council, had communicated with the Institute of Civil Engineers, asking for the names of one or two gentlemen qualified to act for them as hydraulic inspectors, and the names submitted in reply were those of Mr. Unwin, and Messrs. Bramwell and Harris. They had these gentlemen's terms, and he had written himself to a maker of turbines, a Mr. Gilkes. He strongly advised now that these gentlemen should be engaged, either to convince the Board that water was suitable as a motive power or to prove that the ideas held on the subject in that Council were incorrect. If the reports were favourable they could send them to the Local Government Board with a request that the drainage portion of the scheme be allowed to go through on the lines indicated by Mr. Lailey on December 16. so that it would ultimately dovetail in with the electrical lighting portion when that came on. Mr. Lailey proposed at his own expense to submit his portion of the scheme to a member of the institute also, and the report from that quarter could also accompany the one from Messrs. Bramwell and Harris. Mr. Unwin was unable to take the inspection in hand. Messrs. Bramwell and Harris's charge was 30 guineas, and out-of-pocket expenses for travelling. There was another point. No doubt Messrs. Bramwell and Harris based their calculations upon what they knew makers of hydraulic machinery could do, but he thought at the same time that a guarantee from a maker of machinery himself would carry a great weight. He had therefore written to Mr. Gilkes, who happened to be the man who quoted the Brush people for turbines, and he had learned that he was prepared to come for £5. 5s. per day, in addition to travelling expenses. Although it might appear, at first sight, injudicious to have a man who might be regarded as almost interested in the matter, they would see that an engineer who might be called upon to manufacture must be careful about the advice he gave. He formally proposed that these men be engaged to come down, to meet upon the ground, and to examine into and report upon the scheme the Council hoped to carry out. This motion was ultimately adopted.

PROVISIONAL PATENTS, 1894.

FEBRUARY 5.

2451. **Improvements in and connected with electrical concentric conductors.** Carrington Riddell Gordon Smythe, 5, Doune-quadrant, Kelvinside, Glasgow.

2452. **Improvements in thermo-dynamic motors.** Francis William Crossley and James Atkinson, Openshaw, Manchester.

2453. **Improvements in thermo-dynamic motors.** Francis William Crossley and James Atkinson, Openshaw, Manchester.

2487. **Improvements in or relating to secondary batteries.** Charles James Hall, 433, Strand, London.

2493. **Improvements in holders for electric incandescence lamps.** Richard Francis Randell, 55, Chancery-lane, London.

2514. **Improvements in or relating to electric bells.** Julius Henrik West, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

2524. **An electromotor for fans.** Blackman Ventilating Company, Limited, 28, Southampton-buildings, Chancery-lane, London. (Felix Stahl, Germany.)

FEBRUARY 6.

2548. **Improvements in firing keys or electrical contact makers.** Herbert Vivian Keeson, 40, Loudoun-road, St. John's Wood, London.

2562. **Improvements in electrical tramways and railways.** Frank Merwin Ashley, 70, Market-street, Manchester. (Complete specification.)

2607. **An improved magnetic electric conduit system for electric tramways, railways, and the like.** Robert Flebbe, 22, Glasshouse-street, Regent-street, London.

2623. **Improvements in regulating and controlling dynamos.** William Morris Mordey, 46, Lincoln's-inn-fields, London.

FEBRUARY 7.

2677. **An improved printing telegraph and transmitter.** Charles Austin Beck and Leo Kamm, 1, Gresley-road, Hornsey Rise, London.

2693. **Improvements in or connected with phonographs.** Ernest Otto Kumberg and Bernard Eleazar Clarke, 33, Chancery-lane, London.

2721. **Improvements in and connected with insulators for supporting electric telegraph, telephone, and similar conducting wires.** Tyson Sewell and Hans Bodtker, 163, Queen Victoria-street, London.

FEBRUARY 8.

2730. **A new and improved protector for electric cables laid underground.** Thomas Barnet Grant, 15, George-street, Mansion House, London.

2733. **Improvements in or relating to the regulating mechanism of electric arc lamps.** William Charles Mountain and George Theodore O'Brien Carew, 3, St. Nicholas-buildings, Newcastle-on-Tyne.

2734. **An improved electrical contact screw.** James Howard Kerr, 9, Westland-row, Dublin.

2749. **A new or improved register and holder therefor for recording telephonic messages.** Dyson Denison, 2, Market-street, Bradford.

2790. **An improved electric registering apparatus for recording the speed and occupation of vehicles.** Fritz Klaege, 18, Buckingham-street, Strand, London.

2800. **Improvements in incandescent lamp fittings.** Eugéne François Alexandre Soleau, 53, Chancery-lane, London.

2806. **Improvements in electrolytical decomposing apparatus.** Carl Kellner, 46, Lincoln's-inn-fields, London.

2812. **Improvements in methods of and apparatus for the generation of electric currents of defined period.** Nikola Tesla, 45, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Section 103, August 19, 1893, being date of application in United States.) (Complete specification.)

FEBRUARY 9.

2851. **Improved electric signal apparatus.** William Paul Theermann, 11, Great Ducie-street, Manchester.

2866. **Improvements in and having relation to dynamo-electric machines.** William Lloyd Wise, 46, Lincoln's-inn-fields, London. (Isaac Newton Lewis, United States.)

2897. **Improvements in the manufacture of coke or carbon for electrical or other purposes.** Charles Percy Shrewsbury, Frank Lawrence Marshall, John Cooper, and John Laskey Dobell, 57, Chancery-lane, London.

2900. **Improvements relating to the electro-deposition of metals.** Josef Rudholzner, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

FEBRUARY 10.

2936. **Improvements applicable in connection with telemotor apparatus for actuating mechanism at a distance for telegraphing, indicating, steering, and analogous purposes.** Andrew Betts Brown, 87, St. Vincent-street, Glasgow.

2965. **Improvements in holders for incandescent electric lamps.** Julius Herman Geisenheimer and Ernest Augustus Lessing, 4, South-street, Finsbury, London.

2968. **An improvement in electrolysing liquids and apparatus therefor.** Oliver Imray, 28, Southampton-buildings, Chancery-lane, London. (The Farbwerke vormals Meister, Lucius, and Brüning, Germany.)

2976. **Improvements in casings and fittings for electric wires and lights.** Henry Vaughan Lanchester, 13, Bedford-row, London.

SPECIFICATIONS PUBLISHED.

1883.

982. **Telemeter systems.** Brookes. (Dibble.)
983. **Telemeter systems.** Brookes. (Dibble.)
1697. **Electric clock.** Binswanger and Coates.
2203. **Arc lamps.** Gwynne.
2403. **Distributing electrical energy.** Kingdon.
5101. **Electrically interlocking signals and points.** Fletcher.
5778. **Bleaching solutions by electrolysis.** Boult. (Knoefler and another.)
7703. **Electric signalling for railways.** Johnson. (Lattig and another.)
10623. **Printing telegraphs.** Murray.
21430. **Electric lamps.** Robertson.
21734. **Dynamo-electric machines.** Wilson.
21850. **Voltameters.** Naber.
22131. **Electric switches.** Lowrie.
22594. **Electric lamps.** Davy.
23017. **Arc lamp.** Low and Brown.
23897. **Electric signalling.** Reed.
23913. **Dissociating soluble salts by electrolysis.** Haddan. (Blackmore.)

NOTES.

The "Faraday House Journal."—A copy of No. 2 of this journal has reached us.

Derby.—The new Midland Institute, which has just been opened, is lighted throughout by electricity.

The Electro-Harmonic Society.—As stated in our last issue, a ladies' night of this society will take place this (Friday) evening at St. James's Hall Restaurant, Regent-street, W.

The Madras Electric Tramway.—It appears that progress is being made with this tramway, and that the central station is approaching completion. The engineers hope soon to be laying over 200ft. of double line per day.

Enfield.—It appears that the Enfield Local Board, in reply to advertisements, have not received any tenders for the lighting of the locality by oil. The Local Board should consider the advisability of introducing the electric light.

Newport.—The chairman of the Newport Gas Company imagines that the supply of electricity by the Corporation will entail a loss, "as elsewhere." Why does Mr. E. G. Phillips not be sure of his statements before he makes them?

New Launch.—A new launch, the "Britannic," built by the Thames Electric and Steam Launch Company, was put in the water on Wednesday at Eel Pie Island, Twickenham. The launch is 75ft. long, and is the largest constructed on the upper reaches of the Thames.

Transformers and Alternators.—Messrs. Pyke, Harris, and Co., Limited, have issued new lists containing particulars of some of their specialities. These include small transformers, vacuum tube letters, and alternators for lighting and laboratory purposes.

Yorkshire House-to-House Electricity Company.—We have received a copy of the report and accounts of this Company, to be presented at a meeting to be held on Tuesday, March 6, at the offices of the Company, Whitehall-road, Leeds, at 2.30 p.m. The report and accounts will be published in our next issue.

Bournemouth.—The Sanitary Committee of the Town Council last week reported that they had deferred consideration of the surveyor's report with reference to flushing the sewers with fresh water, in order that Mr. Lacey might obtain information with reference to the Hermite system of electrolysing sea-water, by which it is converted into a disinfectant.

University College Chemical and Physical Society.—The annual public address will be delivered in the Chemical Theatre of University College, Gower-street, W.C., by Prof. J. Millar Thompson, F.R.S.E., on Wednesday next, the 28th inst. The subject is "Some Phenomena Connected with Solution and Crystallisation." Prof. W. Ramsay, F.R.S., will take the chair at 8 o'clock.

New Cables.—During the past year the Telegraph Construction and Maintenance Company have laid a cable between Bonny and Cameroons for the African Direct Telegraph Company. A second, connecting the Azores Islands with Lisbon, for the Europe and Azores Telegraph Company, and a third from Zanibar to the Seychelles and Mauritius for the Eastern and South African Telegraph Company have also been laid.

"Directory of Telegraphic Addresses."—Mr. H. Sell has now been successful in producing his "Directory of Telegraphic Addresses" in a complete form by the addition to the present (eighth) edition of telegraphic addresses, obtained from official lists supplied by the authority of the Postmaster-General. The telegraphic and other addresses of upwards of 40,000 firms are given, besides other useful information, including a gazetteer of the leading towns in the kingdom.

Lectures.—The Carpenters' Company has arranged for a short course of six lectures to be delivered at their hall in London-wall on Wednesday evenings on matters connected with building. Several of them are likely to be of considerable interest, not only to working-men engaged in the building trade, but to all students of electricity, engineering, and architecture. The first lecture, by Prof. Unwin, F.R.S., was delivered on Wednesday, the subject being "Niagara and the Works for its Utilisation."

Royal Meteorological Society.—The monthly meeting of this society was held on Wednesday evening at the Institution of Civil Engineers, Westminster, Mr. R. Inwards, F.R.A.S., president, in the chair. Papers were read on the following subjects: "Temperature, Rainfall, and Sunshine at Las Palmas, Grand Canary," by Dr. J. Cleasby Taylor; "Report on the Phenological Observations for 1893," by Mr. E. Mawley, F.R.Met.S.; and "Comparative Observations with two Thermometer Screens at Ilfracombe," by Mr. W. Marriott, F.R.Met.S.

"Electrical Literature."—This is the title of a monthly publication which is intended to supply a brief synopsis, in a classified form, of each important article and editorial that may have any bearing on any phase of electrical engineering appearing in any publication, either American or foreign. It is a continuation of the synoptical index formerly appearing in *Electrical Engineering*. Only one subject appears on a sheet, the reverse of the sheet being blank, and each subject sheet is indexed independently of the running page number of the volume.

Fountain-Lighting.—The Warminster Local Board have accepted from Mr. W. F. Morgan, the chairman, on behalf of the town, a drinking fountain of red granite erected in the Market-place. An electric arc lamp has been placed at the summit of the fountain. The arc lamp is of the Brockie-Pell type and of 2,000 c.p., and the current is obtained from the electric lighting plant of Mr. Mark Hill, of the Station Sawmills. Provision has been made for the erection of three additional lamps, by means of which the whole of the Market-place will be lighted by electricity.

Electrical Apparatus.—A new catalogue of electrical apparatus has been issued by Messrs. Dorman and Smith, of Ordsal Electrical Works, Salford, and 11, Grocers' Hall-court, Cheapside. Among the firm's manufactures, which are now well known, may be mentioned holders for base loop and base-capped lamps, suspension holders, the D. & S. porcelain switches of various types, carbon break switches, and main switches and switchboards. In addition to these, the firm make accumulator regulators, distributing fuse-boxes, wall sockets, and a large variety of electric light fittings.

Village-Lighting.—As stated in our last issue, the village of Great Missenden, on the Metropolitan Extension to Aylesbury, is now lighted by electricity. A 15-h.p. steam-engine drives a small dynamo which supplies 15 lights of 32 c.p. each. The conductors are carried on wooden posts, and the charge for keeping the lamps alight up to half-past ten on dark nights will be £15 per annum. The company (the British Volta Electric Glow Lamp Company) who has introduced the supply expect a considerable demand for the light for domestic purposes, and will also supply it for cooking.

Digitized by Google

Smoking Concert.—Last Friday evening the staff of the City of London Electric Lighting Company, Limited, assembled, together with several friends, at the London Tavern, Fenchurch-street, at a smoking concert organised by the City Electric Athletic Club. The chair was taken by Colonel H. C. Seddon, who was supported by Mr. Bull, secretary of the company; Mr. Cooke, the manager; and Mr. E. J. Frowein, Mr. R. Hunter, Mr. A. F. Harrison, and Mr. S. T. Jordan, the four last named forming the committee of the entertainment. A varied and good programme was provided.

The Government and Telephony.—Mr. A. Morley, replying to Captain Bagot in the House of Commons, on Tuesday, said that under the agreement now in course of negotiation, the Post Office will take over the entire trunk-wire system of the country, and pending the completion of the agreement the company have undertaken to abstain from laying down any new trunk wires. The Post Office is now itself gradually carrying out the scheme of providing trunk wires between the important towns of the United Kingdom, and the claims of Kendal will be duly considered along with those of other towns.

Lighting at Cardiff.—A deputation of members of the Lighting and Electrical Committee of Cardiff Corporation visited Bristol last Friday for the purpose of inspecting the system of public and private electric lighting now in operation there. The deputation, under the guidance of the local engineer (Mr. Proctor) examined the plant and apparatus at the generating station during the early part of the day, and in the evening they saw the lighting both in the public streets and in various business places and private houses. At a forthcoming meeting of the committee the deputation will make an informal report containing several interesting points on the matter.

Caustic Soda and Bleaching Powder.—The prospectus has been issued of the Electro-Chemical Company, Limited, the registration of which is announced in another column. The company is being formed with a capital of £200,000, divided into 40,000 shares of £5 each, for the purpose of working in the neighbourhood of the coal and salt fields in the North of England, the electrolytic process for the decomposition of salt, and the production thereby of caustic soda and bleaching powder, that has for the past two years been carried on at Snodland, Kent. The reports accompanying the prospectus are by Dr. J. Hopkinson, Mr. J. Swinburne, Mr. J. Leith, and others.

Tramway Traction and Lighting.—Mr. W. J. Carruthers-Wain mentioned on Monday, at a meeting of the London, Deptford, and Greenwich Tramways Company, that the Connolly oil-motor would soon be running again on the company's lines. He stated that one method of increasing the traffic was to make the cars as attractive as possible by fitting them up with the electric light. Hitherto the difficulty and the expense have been drawbacks, but the speaker understood that they were now within measurable distance of having electric light supplied to them which would be steady, effective, and cheap. If it combined those attributes, they would be only too glad to introduce it in the cars.

The Extraction of Zinc.—An electrolytic process for the extraction of zinc, says *Engineering*, is attracting much attention in Sweden, where some very telling and satisfactory tests have been undertaken. The zinc extracted in this manner is equal to the best zinc in the market. The most important point in connection with the new process lies in the fact that it can be applied to zinc ore of very poor quality (for instance, the sulphur ore found at Faln), such as the Vieille Montagne Company have not thought it worth their while to exploit. Pure metallic zinc has not been produced in Sweden for some 20 or 30 years, whilst the imports into Sweden of zinc are of some importance.

The Niagara Power Station.—The first practical test of the hydraulic tunnel which has been under construction at Niagara Falls during the past three years, was made on the 25th ult. The test afforded a practical demonstration of the new works, which have already cost nearly £800,000. The Niagara Falls paper mill, which is the first to get the benefit of the power, is the largest of its kind in the world. Its contract is for 6,600 h.p., one-half of which is being used now, and the cost, including the lease of the land occupied by the mill, is 32s. per horse-power per year, for 24 hours per day, the cheapest, it is said, ever obtained. The mill is now in full operation. The hydraulic tunnel has a capacity of 120,000 h.p. The formal opening of the general power-house, where 5,000-h.p. turbines will operate 5,000-h.p. electric generators for the transmission of power, is announced to take place on June 1.

Electric Light Fittings.—Judging from the large catalogue of electric light fittings which has reached us from Messrs. B. Verity and Sons, of Aston, Birmingham, practically every article or appliance included under this head is produced by the firm. Even this is distinct from the catalogue of high-class London fittings, an *edition de luxe* of which is now being issued by the London house of the firm in King-street, Covent Garden. The present catalogue, which is divided into 21 sections, deals with brass or brass and copper brackets, combination gas and electric brackets, electroliers, coronæ and billiard lights, sliding pendants, shade lamps and brass standards. Apart from these, there is a large and varied selection of similar fittings in wrought iron, or iron and copper, and a collection of ship and mine fittings, brackets, and lamps for external use, reflectors, glass and opal shades, and silk, paper, and cardboard shades.

The Pacific Cable Scheme.—Mr. Sandford Fleming, director of the Canadian Pacific Railway, published on the 15th inst. a reply to the strictures of Mr. John Kidd, the Postmaster-General of New South Wales, on the Pacific cable scheme. He said that Mr. Kidd, if he was properly reported, is the only public man in Australia who entertains views antagonistic to the scheme. Every objection to the project will be met, he adds, when the conference of colonial representatives assembles at Ottawa next June. The Hon. Robert Reid on Monday met the members of the Colonial party of the House of Commons, who had assembled in one of the committee-rooms to hear an address from that gentleman, who is Minister of Defence for the Colony of Victoria, on "Colonial and Imperial Defence." The hon. gentleman advocated the construction of a telegraphic cable across the Pacific in conjunction with the Governments of Canada and Australia, and improved postal communication.

Search-Lights on the Manchester Ship Canal.—Since the opening of the Ship Canal for traffic many ship-owners and master mariners have been rather afraid they would be unable to navigate the canal successfully during the night, and hitherto only one or two of the regular coasting vessels have attempted the task. A Manchester firm have brought forward a powerful electric search-light, by means of which the captain of a vessel can navigate the canal during the night with the same ease as during the day. The responsibility of the search-light rests upon Mr. W. J. Croft, who has had much experience with it in many parts of the world. The search-light consists of a 24in. projector, with the necessary mirrors and reflectors, and is

Digitized by Google

supported in a cradle, so that the light can be thrown in any direction. In addition to the search-light, which has a candle-power of between 40,000 and 50,000, a light of between 8,000 c.p. and 10,000 c.p. can be placed at the mast-head of a vessel when loading. The "Ohio" was the first vessel to try the light on the canal recently, but owing to her lightness and the heavy gale she was unable to leave her moorings. The search-light, however, was tried, and Captain Atkinson expressed great satisfaction with it. Mr. Croft has adhered to the canal regulations, and by certain arrangement of the lens it is said that no inconvenience will be caused to vessels coming in an opposite direction to that carrying the light.

Engineering Trade Section of the London Chamber of Commerce.—A meeting of this body was held on Monday, Mr. W. J. Fraser occupying the chair. The question of the Antwerp International Exhibition, 1894, was brought prominently before the meeting with a view to inducing the members of the section and the trade generally to exhibit. It was stated that the exhibition was a very promising one, as Antwerp was an important seaport visited by merchants and all classes from all parts of the Continent and within easy reach of England; that the duties in Belgium were low; that it was under Royal patronage; and that a joint committee representing the Mansion House and the London Chamber of Commerce was acting in London in the interests of the British section. After an expression of opinion it was proposed by Mr. Fortescue Flannery, J.P., seconded by Mr. A. Brebner, and carried unanimously: "That in view of the great progress recently made by engineering science on the Continent, and the prominent and accessible position of Antwerp as a site for exhibition, the engineering section of the London Chamber of Commerce cordially recommends the forthcoming Antwerp exhibition to the general support of the engineering and allied trades throughout the United Kingdom." It was then proposed by the chairman, seconded by Mr. Brebner, and carried unanimously: "That the chairman of this section, Sir Edward H. Carbutt, Bart., be requested to confer with the exhibition authorities as to the appointment of jurors for the engineering section."

Magnetisation by Very Small Forces.—A paper on this subject by Mr. P. Culmann was recently published in the *Elektrotechnische Zeitschrift*, and a *résumé* of it is given in the "Foreign Abstracts" of the Institution of Electrical Engineers. The author pointed out that in 1887 Lord Rayleigh published experiments which went to show that for forces from $4/10^5$ to $4/10^2$ C.G.S. units (unannealed Swedish iron wire) the magnetisation was directly proportional to the magnetising force. Herr Roessler in a recent series of articles has cast doubts on the accuracy of this conclusion, since he found deviations from proportionality amounting to 20 per cent., and he puts down Lord Rayleigh's failure to observe this to his method of observation, in which he only measured a presumably minute difference between quantities in themselves very small. The author does not agree with this objection, holding that Lord Rayleigh's method, in which differences alone are observed, must necessarily be more accurate than one in which the difference is between two larger deflections, of which it forms but a small proportion; and though the observed quantity is small, much more sensitive apparatus can be used (in Lord Rayleigh's experiments an $H = 0{\cdot}00004$ C.G.S. unit gives a deflection of 1·5mm., and this is about 50 times the sensitiveness of Herr Roessler's method). The author has calculated the amount in actual length of the deviation from proportionality observed, which is 0·25mm., and therefore concludes that we need not modify our views on the laws of very weak magnetisation as formed some time since on the basis of Lord Rayleigh's research.

Testing of House Installations by Supply Companies.—We are pleased to give space to the following circular which has been issued by Mr. David Cook, engineer and manager to the City of London Electric Lighting Company, Limited: "The attention of the company is frequently drawn to defective insulation of electric conductors and fittings on consumers' premises. This may arise in a great variety of ways, but chiefly through employing inferior material and workmanship in wiring the buildings or allowing good installations to get into disrepair. When considerable leakage occurs, the meters may register the lost current as if used by the consumer. Damage to buildings and fittings may also be occasioned. Unless careful tests are made by skilled men, leaks and incipient faults may long remain undetected, growing worse as time goes on. At present there is no public or other body charged with the duty of making tests on private premises, although an opening appears to exist for a testing authority of the kind. With the object of filling this want and placing within the consumer's reach a ready means of lessening any loss or risk, the City of London Electric Lighting Company, Limited, hereby gives notice that it is prepared to enter into agreements with consumers to examine their fittings, etc., at stated intervals on payment of an annual fee of 10s. The men who make the test will hand the consumer a signed report specifying the insulation resistance, with a note on the general condition of the wires and fittings at time of inspection."

The E.M.F. of Starlight.—Mr. George M. Minchin writes to *Nature* from Westmeath, whither he went with the object of trying whether or not it is possible to obtain measurable E.M.F.'s from the light of the planets and the fixed stars. After one night's work, Mr. Minchin was able to announce the remarkable discovery that, with the apparatus he employed for the purpose, the E.M.F. of starlight is easily measurable. The electrometer employed was Clifton's form of the quadrant electrometer of Lord Kelvin. The telescope was Mr. Wilson's 24in. reflector; and the photo-electric cell, attached to a cell-carrier was connected with the telescope in place of the eyepiece, and could be moved in and out of the image of the star at pleasure. The area of the sensitive plates in the cell was about three square millimetres. A force of one volt was represented by 460 divisions of the scale, and the light of Venus gave something like 40 divisions. Only about one-quarter of the disc of the planet was then illuminated, so that its whole light would be represented by 80 divisions. Thus the light of Venus when concentrated by this telescope is represented by about 0·17 volt. With Jupiter, about 14 divisions on the scale were obtained, but no conclusion can be drawn from this, because the image of Jupiter covered much more than the area of the sensitive plate. From the light of Sirius a force of 0·02 volt was obtained, being a little over nine divisions on the scale. An attempt on Aldebaran was not productive of any certain result. Mr. Minchin observes that the relative values of the lights of Venus and of Sirius as given in the "Encyclopædia Britannica," article "Photometry," are most probably erroneous, the brilliancy of Venus being greatly underrated.

The Hermite Process at Worthing.—In the course of a communication to the *Lancet*, a correspondent says: "It is expected that shortly the experimental plant and machinery which have been erected in West-street will be quite ready for demonstration by M. Hermite. The Town Council have consented, as a preliminary test experiment, to place a small row of houses at the disposal of M.

Digitized by Google

Hermite, in order that he may demonstrate the working conditions of the process. For this purpose the houses have been fitted with cisterns and pipes to supply the 'electrolysed fluid' for flushing purposes. At present the sewers are laid open to admit of inspection when the whole plant is in action. The treated sewage discharge is to fall into an intercepting syphon fitted with a screening arrangement, into which solid matters are temporarily deposited, but by the continued flow of 'electrolysed fluid' over this deposit the fæcal matter, so it is asserted by the inventor, is disintegrated and gradually destroyed. The plans and arrangements at this experimental station have been carried out under M. Hermite's instructions. The Town Council are moving no more in the matter for the nonce than to offer M. Hermite every facility for carrying out a fair experiment. Disappointment has been expressed in several quarters at the seeming delay of the trials which have been announced pretty freely in the press to take place shortly, but the electrical engineers appointed by M. Hermite have got to work, and they have for some time been steadily fixing the necessary plant and adjusting it to meet the especial requirements of the present case. The date of the trial is not definitely fixed, but the inaugural ceremony will be looked forward to with keen interest."

The Effect of Lightning upon Trees.—It is not for nothing that the "blasted oak" is a familiar adjunct of gruesome fiction. Oaks, according to a scholarly note on the subject by M. Dimitrie, stand a far greater risk than almost any other tree of being struck and injured by lightning. M. Dimitrie's experiments were conducted with a Holtz electrical machine, and samples of different woods. Under similar conditions the spark would penetrate oak in from one to two revolutions of the machine, poplar or willow in five revolutions, beech in from 12 to 20; showing at once a great difference in the electrical conductivity of various woods. The experiments were conducted with living and with dead specimens of wood, and showed that dead wood was more liable to be struck than living. The scientific explanation at the bottom of this difference was found to depend upon the richness or poverty, relatively, of starch and oil. Starch-giving trees, oak, poplar, willow, maple, elm, and ash, oppose much less resistance to lightning than fatty trees, such as beech, walnut, lime, and birch. The fir, which varies greatly with the seasons in regard to its oily contents, can be shown from actual statistics to be as susceptible to lightning stroke in summer as the oak, and as little susceptible in winter as the beech. Bark and foliage are naturally bad conductors, and so is the wood at the core of all trees. In support of his own experiments, M. Dimitrie quotes records from the forests in the principality of Lippe, taken during three different years. The trees struck were as follows: oaks 159, beech 21, pitch pine 20, firs 59, various other trees 20. The relative numbers of these trees in the forests were: oaks 11 per cent., beech 70 per cent., pitch pine 13 per cent., and fir 6 per cent. The risk to pitch pine is thus five times, to fir 33 times, and to oak 48 times greater than it is to beech. These results are curious and noteworthy.

The Aberdeen Electric Light Station.—The inaugural ceremony of setting the plant in operation at this station is announced to take place on Tuesday next, the 27th. The Town Council obtained a provisional order in 1890, and the system adopted is based upon a report by Prof. A. B. W. Kennedy. The initial stages of the work were begun before the appointment of an electrical engineer, but since September last the station has been in the hands of Mr. E. T. Ruthven-Murray, the electrical engineer. The generating station in Cotton-street will be capable of supplying 10,000 lamps of 8 c.p. The electric light undertaking is to be worked in conjunction with the gasworks, an arrangement which was adopted in view of its economy and efficiency. The station is in the grounds of the gasworks. The building comprises three main parts—namely, the boiler-room, the engine and dynamo room, and the battery and switchboard room. In the basement is situated the boiler-room, which contains four Babcock and Wilcox boilers. Three of these are of 90 h.p. each, with a working pressure of 150lb. The feed-water is heated by means of the exhaust steam. On the same floor as the boilers, but separated from them by a wall, is the engine and dynamo room, which has space for the erection of additional plant when necessary. At present it contains five engines, two of these being of 40 i.h.p., running at 520 revolutions per minute; and three engines of 80 h.p., running at 480 revolutions per minute. These engines are all coupled direct to corresponding dynamos of the Elwell-Parker type. The switchboard is arranged in the same room as the dynamos. Storage batteries will be used to meet the requirements when the demand for light is low. From the station the current is conveyed by means of copper conductors arranged in concrete culverts. The engine-room has accommodation for additional machinery to the extent of 1,500 h.p., so that extension of the buildings will not be necessary for a considerable time.

Alternate-Current "Rectifiers."—The advantages of alternating currents are many and important, but by no means exhaustive so far as the practical requirements of electric lighting and power applications are concerned. They have hitherto failed wholly to serve for charging accumulators on a reasonable scale, or in carrying out any of the more usual processes of electro-chemistry; besides which, their employment for actuating small motors—such as might be installed in a private house, factory, warehouse, shop, etc., with energy outputs up to 5 h.p., or, perhaps, 10 h.p.—appears to involve a terrible amount of trouble in the arrangement of suitable and even approximately efficient working conditions. It is therefore hardly to be wondered at that a considerable amount of inventive energy has been spent upon devising apparatus in which alternate currents may be converted cheaply and economically into continuous currents for such purposes as street-lighting and motor work. Amongst the foremost of experimenters in this direction has been Mr. Ferranti, the principle adopted in his apparatus being simply that of a rotary commutator driven by a small alternating motor supplied with current from the alternating mains, synchronously with the supply station generator. The alternate currents are passed through the commutator in such wise that the collecting brushes receive a continuous current, practically as in all continuous-current machines, where the current generated is of an alternating form commuted at the collector. Of course, modifications of this general principle have been devised and experimented upon; and at the present time we understand that important tests upon rectifiers after this kind are being made under the supervision of Mr. W. H. Massey. Mr. Massey is said to be desirous—if it be practically possible—of introducing some such arrangement into the town lighting scheme for Cardiff, which he has in hand. Obviously there are great advantages in direct-current working for the street lamps alone as compared with the use of alternate currents. No reflectors are required in the former case, but the expense of running special mains for the street lights (as in the City of London) and the employment of special machines prove somewhat considerable obstacles in the case of smaller cities and towns. If a small synchronous alternating motor of ½ h.p. at the outside

Digitized by Google

is all the mechanism required in a sub-station to convert the alternating into continuous currents by the aid of a rotating commutator, then such an appliance may obtain quite an extensive use under certain conditions. Of course, there are some practical difficulties in the way, and not the least of these appears to be the extreme care necessary for preserving a suitable ratio between the alternating period and the time of commutator rotation. This obstacle may doubtless be fully overcome as our knowledge increases of the working conditions.

A Mountain Electric Railway.—The Mount Lowe Railway, in Southern California, is a remarkable achievement in mountain railway construction. Its object is to connect Pasadena, a beautiful and famous residence city near Los Angeles, with the summit of the Sierra Madre Mountains, nine miles distant and 6,000ft. above sea-level. The mountain road starts from Altadena, a point 12 miles from Los Angeles and three miles from Pasadena, at the terminus of a local steam railway which ascends the foothill mesa of the mountains to an altitude of 1,500ft. The first 2½ miles of the Mount Lowe Railway is an electric trolley line, and climbs up the remainder of the mesa for a mile and a half, and then penetrates Rubio Canyon, a deep and romantic gorge, for another mile. The trolley terminates at Rubio Hotel and Pavilion, a unique structure built across the canyon at an altitude of 2,200ft. From Rubio Hotel, a double-track, three-rail, endless cable incline, 3,000ft. in length, lifts the passenger to the summit of Echo Mountain, 3,500ft. above the sea, overcoming in eight minutes an altitude of 1,300ft., and passing over a varying gradient which ranges from 48 to 62 per cent. Two cars of peculiar construction are provided with transverse seats arranged in three compartments, rising above each other like steps. These cars are permanently fastened to the cable, and one ascends as the other descends, passing each other at an ingenious automatic turnout in the centre of the incline, 1,500ft. from either end. Like the trolley line below, this road is operated by electricity, and is with one or two exceptions the only cable incline in the world operated by electric power. The winding machinery and motor are located in a power-house on Echo Mountain, the plant having been designed and constructed by A. S. Hallidie, of San Francisco. The 1½in. cable is driven by a 75-h.p. Keith electric motor, making 800 revolutions per minute, which, by three reductions, drives a horizontal clip pulley or grip sheave of the Hallidie type, making 17 revolutions per minute. This grip sheave is provided with movable automatic jaws and with a band brake. The conductor of the incline car can signal the engineer at the motor-house at any point on the incline, and stop the car or proceed at will. The dynamo which furnishes the current for the entire system is an Edison bipolar generator, is located in the company's power house at the Altadena station, and is driven by two 60-h.p. Otto gas-engines, the gas being economically manufactured on the premises. An 8in. pipe will shortly be conveying an ample stream of water with a 1,400 foot head to a power-house a mile below the hotel, and two large Pelton wheels will drive the dynamo at a nominal cost. While this great dynamo furnishes power for the trolley line and cable incline, another supplies the electric current for an elaborate system of arc and incandescent lights to illuminate the hotels, canyon, and adjacent grounds.

Economy in the Use of Transformers.—A paper on this subject was recently read by Mr. P. J. McFadden before the North-Western (U.S.) Electrical Association. The author pointed out that in selecting a transformer for a given customer, the central-station superintendent will too often instal one capable of supplying the total number of lights for which the house is wired. In some cases this cannot be avoided, but in houses wired, say, for 40 to 50 lights, he considers that it will seldom be necessary to put up a transformer any larger than a 30-lighter. The neighbourhood, the size of his family, and their habits relative to the probability of entertainments involving the burning of nearly all the lamps in the house, would all with a moment's consideration determine sufficiently closely what the maximum load would be. The author asks whether it is always necessary to instal a transformer for every individual customer? He states that even the bunching of, say, three moderately large transformers to serve four or five consumers where one or at most two are likely to have a large load at one time and where this comes so seldom as to make it expensive to put up for each of them a transformer capable of taking that load, while a step in the right direction, is seldom good practice; for if the primary fuse of one should blow them out not only does the secondary of that transformer (which is now dead, as far as its capacity to give out current is concerned) become a load upon the other two, but also the load of lamps it formerly carried must now be borne by the others. When this is the case, the fuses of the other two will be likely to blow and the whole arrangement disabled. More than one case has recently come to the notice of the author, showing how in practice the substitution of one large transformer for several smaller ones has worked to the saving in first cost to the station, and in the economy of operation as well. Apart from the advantages of regulation and efficiency, there are other and quite as palpable ones that especially recommend this system. Perhaps first of all comes the saving in the first cost. This plan not only preserves this advantage in first cost of large transformers, but also admits of the use of a very much lower capacity than the aggregate of the lamps wired up. There is a greater saving in the cost of installation and in the cost of repairs. Further than this, the danger from lighting in the primaries is reduced at least in proportion to the number of transformers replaced. These remarks concerned the use of large transformers with secondaries connected on the ordinary two-wire system, using, if desired and the distances are not great, 52-volt lamps; otherwise, 110 volts; but why stop here? The very reason the alternating system was adopted was on account of the saving in copper in the mains and feeders, and this was done by sending a small current to a great distance at a high voltage, knowing that it is only amperage that demands a large cross-section of copper. Now, he asks, why not apply this principle to the secondary wiring as well, using as high a voltage as is permissible in practice? Manifestly, this can be accomplished by running the secondary wiring on the three-wire system having a difference of potential of 220 volts between the outside wires, and using 110-volt lamps. Here, again, is introduced a feature that, added to those above enumerated as being present in the use of large transformers, makes the system of three-wire secondary wiring from transformers the most efficient that modern practice is capable of. The loss in the secondary wiring is here cut down to minimum, as the current is only one-fourth of what it would be with an equal number of lamps of 52 volts and for the same percentage of loss, the actual drop in volts can be doubled. As a consequence the wire for a 220-volt circuit would need to be but $\frac{5}{64}$ of that for a 50-volt circuit. Ordinary transformers can of course be connected in pairs with their 100-volt secondaries in series, and run out on three-wire, but he opines that a still greater saving is secured in using a transformer whose secondaries are so brought out that a three-wire service is obtained directly from the one transformer.

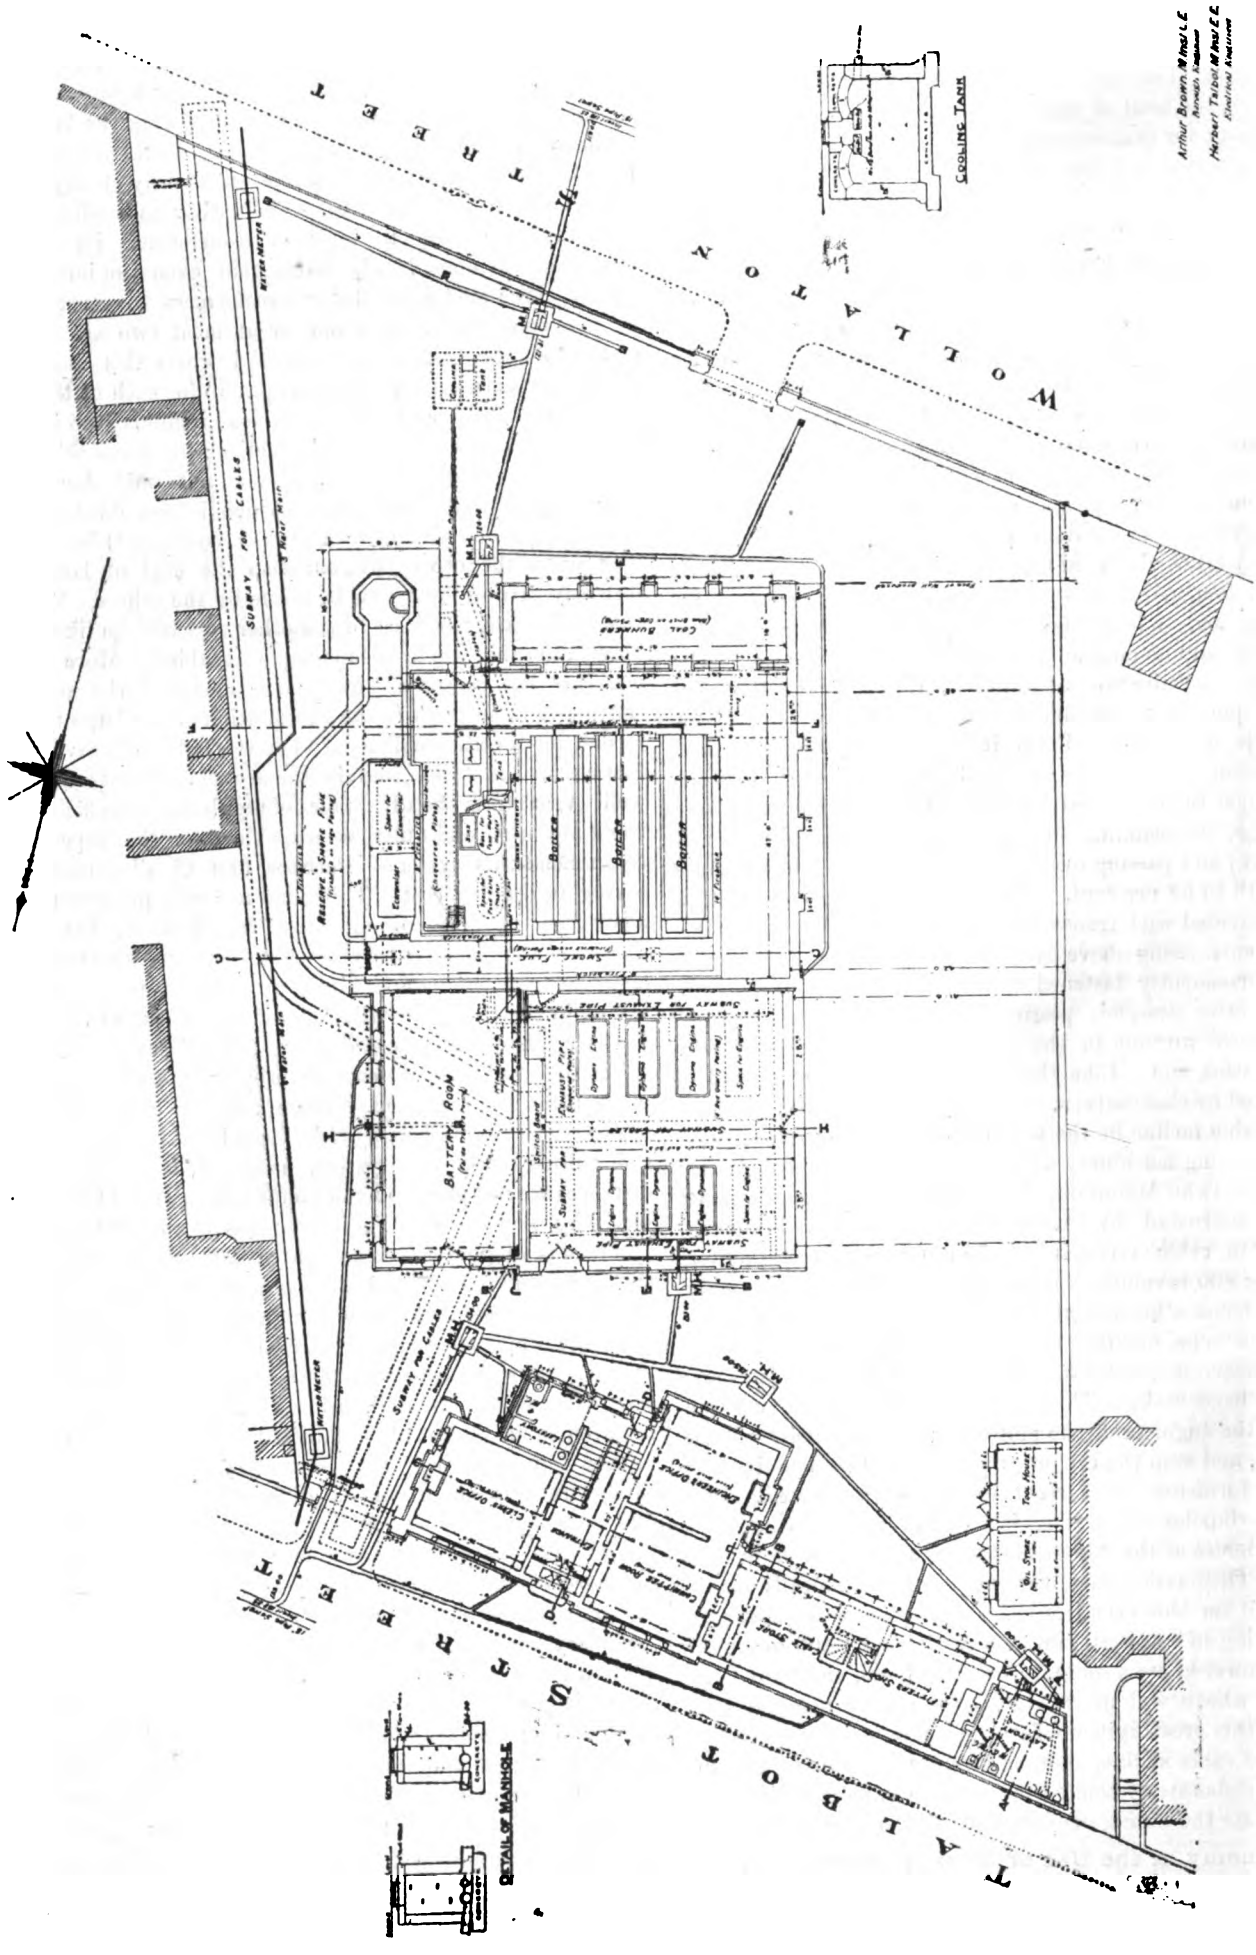
THE NOTTINGHAM MUNICIPAL ELECTRICITY WORKS.



Nottingham Municipal Electric Light Station—Ground Plan.

The history of the electric lighting question in Nottingham is somewhat similar to that in other large boroughs. The consideration of the question was relegated by the Town Council to a special committee, and one of the first

questions which they had to decide was whether they should allow the supply of electricity to be taken in hand by a private company or whether they should undertake the supply themselves.

these gentlemen strongly advocated that the Corporation should undertake the supply of electricity. The Corporation of Nottingham, as pointed out by Mr. Preece in his report, are already the purveyors of gas, and have an

of supply, and the Corporation were according to the order compelled to lay distributing mains in 18 of the principal streets in and near the Market-place, which is the business centre of the borough. After having received the reports of the two experts, the Electric Lighting Committee visited some of the most modern electricity supply stations, both in and out of London, and gained most valuable information.

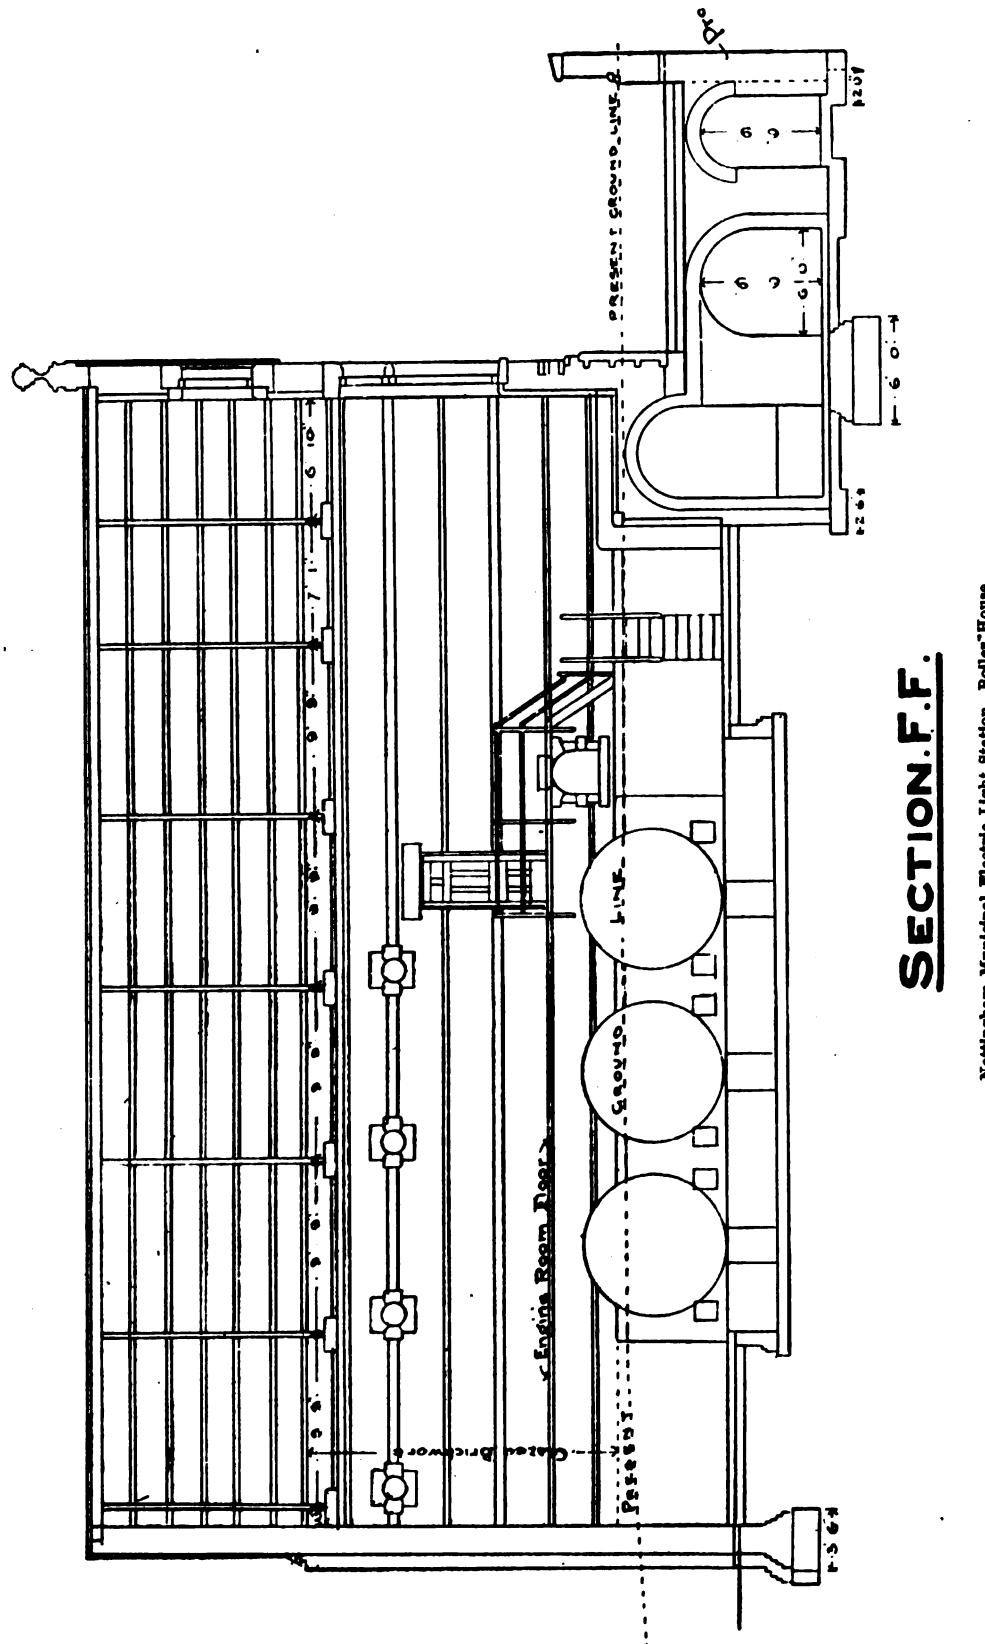
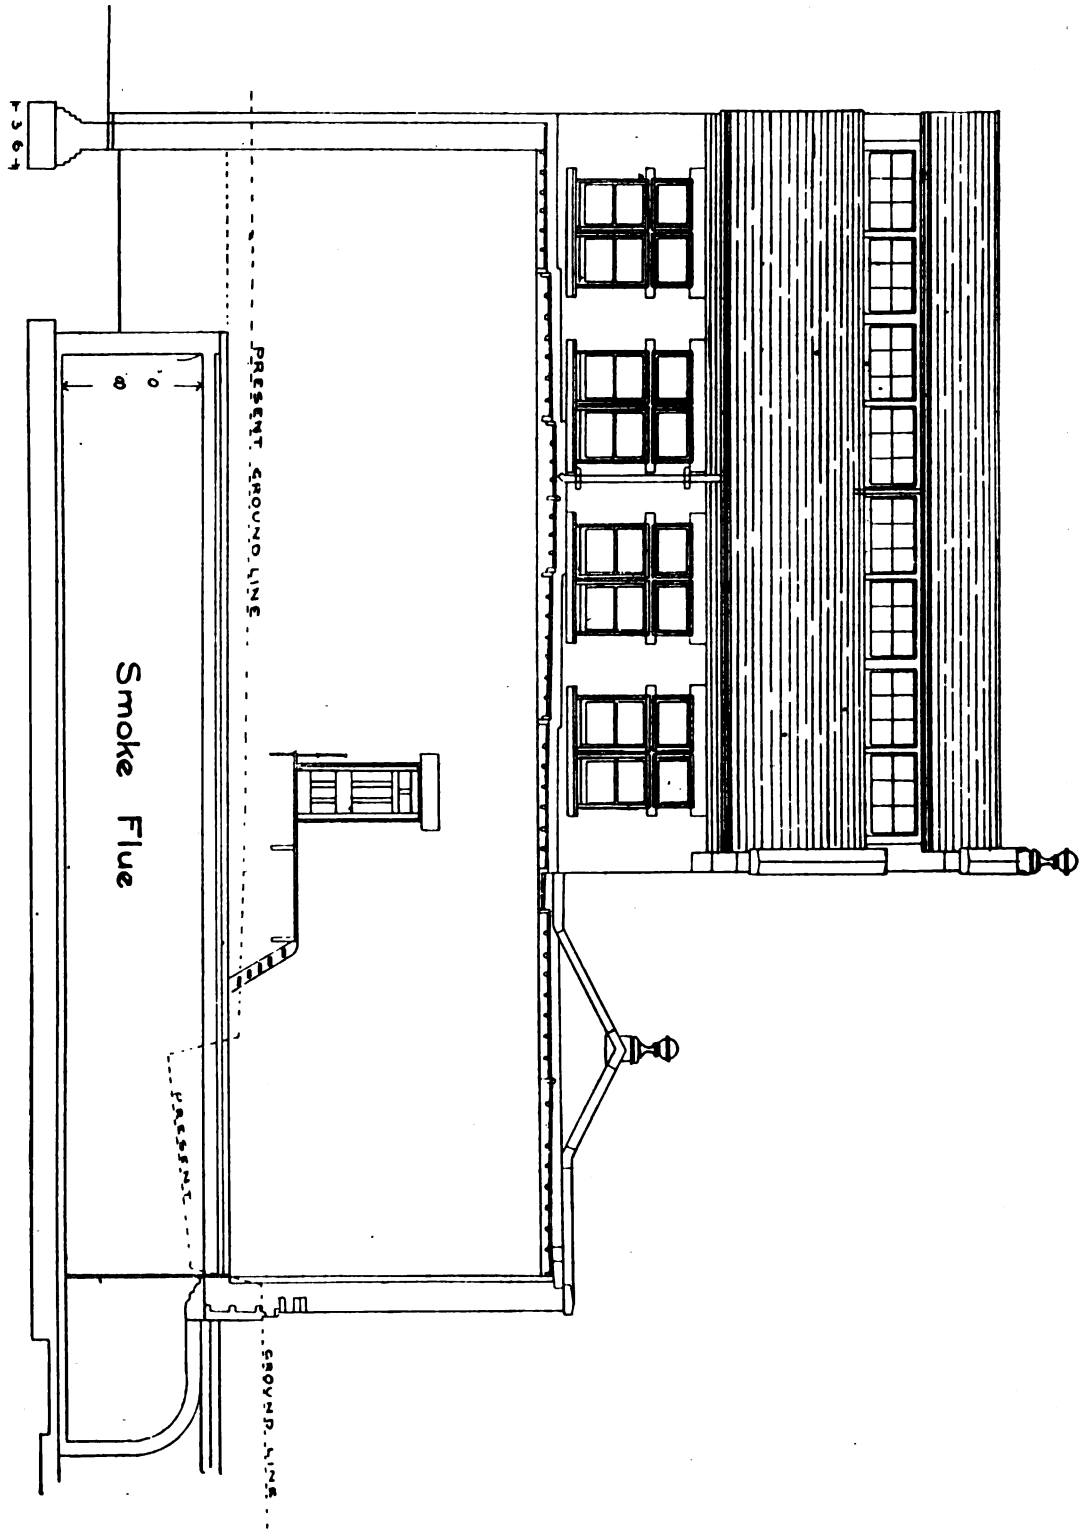
a demand for this in the district near and around the Market-place. As the demand for the light increases, and it is necessary to supply the light beyond the radius in which the low-pressure continuous-current system may be economically worked, there may be combined with this the high-pressure continuous-current system transformed to low pressure by motor generators to meet the requirements of the residential part of the town. Considerable difficulty was experienced in finding a suitable site for the generating station. It was of importance that it should be as near as possible to the centre of the area to be supplied, but the high price of land and property rendered the purchase of a site within the immediate vicinity of the Market-place impossible. However, a site eminently suitable was obtained only 300 yards distant from the Market-place; the area of the site is 2,800 square yards, and it has frontages to Wollaton-street and Talbot-street.

The accompanying illustrations show details of the station buildings. The generating station comprises, firstly, a block of buildings facing Talbot-street, with offices for the electrical engineer and his staff, committee-room, and a room in which electrical appliances can be exhibited; there are also a cable-store, fitters'-shop, jointers' shop, and carpenters' shop. The engine-house is situated at the back of the offices and workshops, and the boiler-house, which adjoins the same, has its entrance from Wollaton-street. The boiler-house is 63ft. 9in. by 47ft., and, in consequence of the rapid fall in the ground from



Digitized by Google

north to south, the floor of the boiler-house is 10ft. below the floor of the engine-house. There will be four boilers of the Lancashire type, 28ft. long by 7ft. diameter; three of these boilers are now on order from Mr. E. Danks, of the Oldbury Boiler Works, near Birmingham. In the main flue is fixed a Green's fuel economiser of



SECTION C.C.

128 tubes, and a Berryman feed-water heater is being supplied by Messrs. Jos. Wright and Co., of Tipton. The same firm is also supplying two of Pearn's automatic quadruple-acting vertical flywheel pumps for feeding the boilers. The feed-pipes will be arranged so that the feed-water can be passed either through the economiser or heater separately, or through the two in series. The whole of the steam-pipes are being supplied by Messrs. Lloyd and Lloyd, of the Albion Tube Works, Birmingham, and will be of mild steel throughout; the branches and flanges will be electrically welded on solid. The steam-main in engine-room is being constructed in the form of a ring, and will be fed at different points from the main in the boiler-room. Hopkinson's patent parallel slide valves are being used throughout, and one is placed in the main steam-pipe between each boiler and each engine. The main steam-pipes are 8in. bore, $\frac{5}{16}$in. steel, with flanges 15in. diameter and $1\frac{1}{4}$in. thick. The boiler pipes and valves are 6in. bore, $\frac{5}{16}$in. thick, and the flanges 12in. diameter and $1\frac{1}{4}$in. thick.

(To be continued.)

The John Scott Legacy Premium and Medal.—The John Scott legacy premium and medal, awarded by the city of Philadelphia upon recommendation of the Franklin Institute, has been granted to Mr. Nelson W Perry for his method of series electric traction.

THE BOARD OF TRADE ON ELECTRIC TRACTION.

On Wednesday last there was held at Richmond-terrace, Whitehall, a conference of those more especially interested in the development or the converse of electric traction, under the auspices of the Board of Trade, when the draft rules prepared by the Board for carrying out and operating electric lines were brought up for discussion and amendment where necessary in the general public interest. So important, however, are the matters involved, that the meeting had to be adjourned until this (Friday) morning in order to complete such full discussion of them as proved desirable, and we must therefore suspend final judgment as to the position and prospects of electric traction, now at last to be clearly defined, though we hope not excessively limited.

In thus bringing the whole question to a final focus—after months of evidence and argument before parliamentary committees, joint and separate; after careful consideration of probable effects upon their interests by the tramway, railway, telegraph, telephone, gas, and water companies (who have each and all claimed with justice to be heard on the subject); after energetic movement on the part of municipalities either now or in the future concerned in the ownership of such undertakings—the Board of Trade is, in the first place, deserving of hearty congratulation upon the exceedingly fair and open way in which criticisms have been invited and amendments (proved reasonable) readily adopted. Such a meed of praise becomes the more due when the true position of the Board is fully realised, and its action better understood. The contrast between the present prospects of electric traction and those of electric lighting when the Bill of 1882 was about to become law, cannot fail to be very striking to those who trace the history of the latter, and are able now to gauge the effect of the rules just compiled in their accepted form; not only can one still express entire confidence in the fairness and want of bias or prejudice in this department of State, but, what is much more to the point, a far greater degree of wisdom and foresight has been shown in this matter—proof positive that the experience already gained is now of service under new conditions.

When it is remembered that the Board of Trade, as a Government executive office, has been in the delicate position of enunciating rules for the conduct of one industry—viz., that of electric traction—which must inevitably affect in a more or less serious manner another industry—that of supplying telephonic communication—which may at an early date become a Government undertaking, the fairness, not of the draft rules themselves, but of the Board in accepting amendments, almost causes one to wonder whether it is because in the somewhat distant future the tramways themselves may be "nationalised," and become a department of State property on an equal footing with telegraphs and telephones. Nowadays, one never knows what political developments may not be in store for us with so great a spread of municipal feeling.

Returning, however, to the draft rules themselves, and the amendments proposed by one party

Digitized by Google

and another of those most interested, it is not so easy to acknowledge the presence of absolute fairness. On many points the Board of Trade proposals actually traverse in a most fundamental fashion the spirit of the conclusions reached by the Joint Parliamentary Committee last year—notably so in Rule 14, the last dealt with at Wednesday's conference. We are glad, however, to see that the position thus assumed by the Board in requiring the tramway company to "avoid injurious interference with any existing wires" has been so far modified that the undertakers of any electric traction scheme will not be called upon to do more than "take all reasonable precautions" against injuriously affecting wires now erected. Apparently the decision as to what is "reasonable" or not is left with the Board of Trade: this is to be regretted in some respects, for although Government inspection may be absolutely impartial, it cannot be always consistent, whilst it must be arbitrary.

Amongst those foremost in suggesting practical alterations and amendments of the rules from an electrical point of view have been the Institution of Electrical Engineers, the Electrical Trades Section of the London Chamber of Commerce, the Association of Municipal Corporations (based on a report of the whole question submitted by Dr. Fleming), and the Imperial Tramways Company, Limited (an interest which has powers and proposals for electric lines of considerable importance and magnitude); and it is pleasing to see that in most instances their suggestions have been adopted. The National Telephone Company has not in any way sought to go behind the Joint Committee's report, although some of its proposed amendments are of too severe a character for an industry struggling to establish itself. Possibly the anticipation of Government purchase may have caused the telephone interests to feel secure of a position at least equal to any that electric traction might attain. Strong criticism is, however, deserved by the proposals made on behalf of the associated railway companies, and although these are only set down for discussion at the meeting to-day, we cannot refrain from saying that they appear to us extremely ill-considered and badly drafted. The first one (additional No. 2) is no proposal at all, but a mere statement. The second is unnecessary, being provided for in an amendment due to the Institution of Electrical Engineers. The third is absolutely impossible—seeking, indeed, to make unlawful any leakage of current whatever to earth. The fourth concerns only the tramway companies themselves, and has no effect at all upon the railway systems; whilst the fifth is absolutely opposed to the Joint Committee's report. Admittedly, the question of electric tramway leakage currents affecting railroad signals is of enormous importance, but the matter may be summed up in Major-General Webber's words, "the protection of block signals lies wholly in the hands of the railway companies themselves." If they are affected in the same way and to the same extent as the telephone systems, they ought surely to be contented with the same latitude allowed to the latter.

Finally, the Gaslight and Coke Company assumes a similar position of "injured innocence," and because its mains are leaky, desires to make someone else suffer rather than put its own house in order. Accordingly, the right to obtain damages against tramway companies (also with leaky mains) is sought for, just as in the old fable the sieve howled at the needle for being so imperfect as to have a hole in it. We are glad to see that Sir Courtenay Boyle very properly threw the onus of such indemnity upon the shoulders of Parliament, where it rightly belongs, instead of the Board of Trade.

REVIEWS.

Electric Waves; being Researches on the Propagation of Electric Action with Finite Velocity through Space. By Dr. HEINRICH HERTZ. Authorised English translation by D. E. JONES, B.Sc., with a preface by LORD KELVIN, P.R.S. London: Macmillan, 1893.

The appearance of this volume, following so closely upon the untimely death of Prof. Hertz, only emphasises the irretrievable loss which science has thereby suffered. At the same time it serves to remind us that one part of Hertz's work was really finished, and that he regarded the identity of electrical and optical radiations as a completely established fact. This thought alone can console us when we reflect what Hertz might have accomplished had he lived.

In the history of a theory four consecutive stages can generally be traced, through the first three of which the ether theory has already passed. The first stage consists in the accumulation of experimental facts which have apparently no connection with each other, except that they are phenomena exhibited by the same body (as, for example, the electric conductivity of solids and their opacity to light), or that they refer to similar results produced by different causes, as in the case of electrical and gravitational attractions. The ether theory of electrical actions was in this stage when Faraday appeared; the theory of gravitation has not yet passed beyond it. As the facts increase in number and new relations between them are gradually discovered we are led to the formulation of a theory, tentatively at first to account for a few phenomena; afterwards, by the aid of mathematical generalisations, we ultimately arrive at a complete explanation of all the facts. The work of Faraday was the formulation of the ether theory; to Maxwell belongs the mathematical development of it.

The task of these two philosophers was, however, rendered much more difficult because a theory already existed, that of action at a distance, by which nearly all the observed facts could be accounted for. The history of this theory is well told by Lord Kelvin in the preface to the present volume. Faraday and Maxwell had not only to combat the notion of direct exertion of force across empty space, but were compelled to produce convincing evidence of the existence of a medium for its propagation before their theory could be considered complete. This necessitated either the proof that a finite time was required for the propagation of electric disturbances (direct action at a distance requiring no finite time), or else the properties of the medium must be identical with those of the luminiferous ether. To fill space with two distinct ethers was quite as repugnant to their minds as to leave it absolutely void. Faraday himself found that the plane of vibration of light was rotated by a magnetic field, but he died without making further progress. Maxwell showed Faraday's observations to be in strict accordance with the new theory; he also worked out the theory of electric waves, and proved that the reciprocal of the square of their velocity of propagation through any substance must be equal to the product of the magnetic permeability and the specific inductive capacity of that substance. Experiments showed that the inverse square root of the latter product was equal

Digitized by Google

to the velocity of light, and thus everything pointed to an identity in the mode of transmitting the two kinds of waves, although so far the evidence was entirely indirect. So ended the second chapter in the history of the theory.

The experimental treatment of electric disturbances, based upon the happy discovery of electric resonance and the interference of electric waves, has formed the life work of Hertz, and is recorded in historical order in the book before us. The author has enriched it by the insertion of an introductory article explaining how he was led to carry out the experiments described. It is impossible to select any one paper of the series as being of more importance than the rest; perhaps for general interest that on "Electric Radiation" (p. 172), will have pre-eminence, as it describes the reflection, refraction, polarisation, and interference of electric waves just according to the manner of light waves, and leaves no room for doubt that the two are absolutely identical except in wave lengrh.

The ether theory of electricity and light has thus passed through the three stages of isolated facts, growth into mathematical form, and proof by crucial experiment. It remains to be seen whether it can survive the fourth stage, that of proving itself consistent with other physical theories. Mr. Glazebrook has already pointed out (British Association Address to Section A, 1893) that the disturbance of the ether assumed in light vibrations is a purely mechanical one—in fact, the whole theory of light vibrations is purely mechanical; while for electric waves the disturbance consists of a displacement of electricity, and its electrostatic and electromagnetic effects are propagated with the velocity of light. Dr. Larmor has shown a way out of the difficulty by postulating that dielectric polarisation is a mechanical strain in the ether, the strain being of a rotational character, inasmuch as it always occurs in a closed curve. This seems a possible explanation, but it must be remembered that the ether has yet other functions to perform. We have still to discover what modifications it undergoes in the neighbourhood of gross matter, a vast subject of which the fringe only has been touched. Indeed, we have no evidence that matter itself is not a modification of the ether. Further, it is as yet quite impossible to answer the questions whether we can ascribe to the same medium the power of conveying gravitational stresses and the stresses exerted by mind on mind, and possibly on matter.

English readers will be glad that Mr. Jones has accomplished the task of translating Hertz's work from the original German, and that the English edition is enriched by a preface from the pen of Lord Kelvin. The translator has done his work well, and the simple straightforward descriptions of experiment and deduction which recall the style of Faraday's writings, have not suffered by being expressed in a foreign tongue. One or two new terms have been invented which we hope may become general. For instance, the combination distance-force is used to express a force directly exerted through space on a distant particle (*Fernkraft*). The Germans have been greatly ridiculed for coining compound words, but when these come to be translated one begins rather to admire the perfection of a language which can concentrate the meaning of a whole sentence into a few syllables. At the same time they prove very troublesome to a translator, and they sometimes cause the translated sentence to lose all the neatness and simplicity which it possessed in the original.

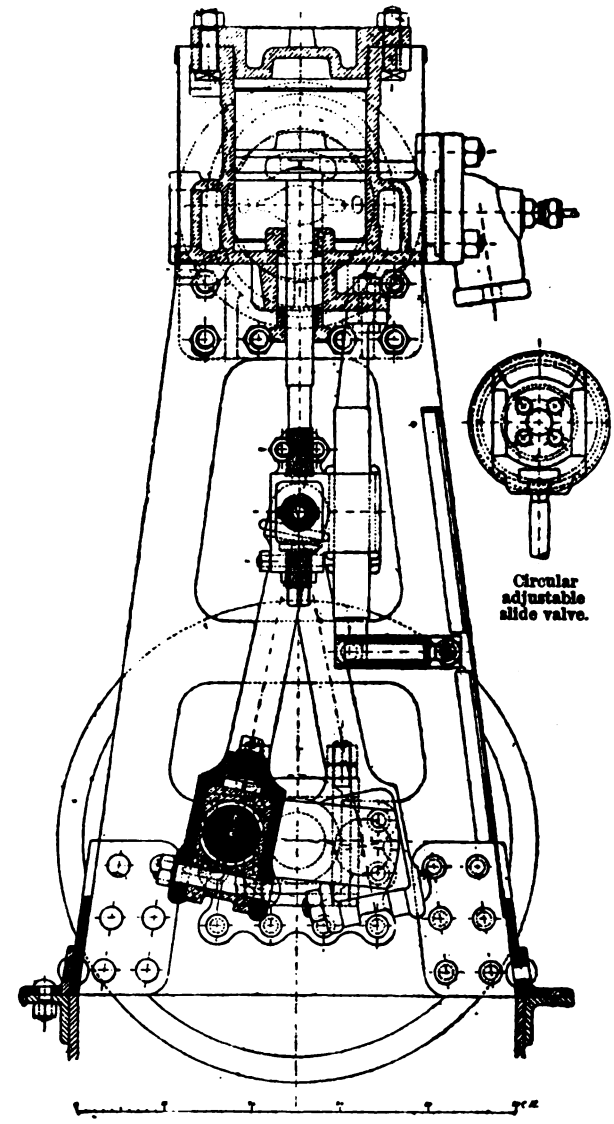
CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

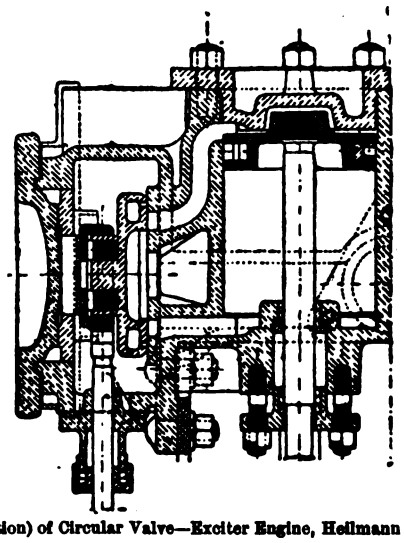
THE HEILMANN ELECTRIC LOCOMOTIVE.

SIR,—There are one or two misprints in the description of the above, published under my name in your issue of last Friday, which I would like to see corrected, if possible. In the first place, the illustration of one of the motors does not represent, as stated, a vertical section *along*, but *across*, the axle. This would be, perhaps, obvious to the reader, but was not altogether clear owing to the motor being shown partly in section and partly in elevation. Secondly, Messrs. Brown, Boveri, and Co. are established at *Baden*, in Switzerland, not at Basle, which is some distance away.



Sectional Elevation—High-speed Exciter Engine, Heilmann Locomotive

Finally, the gross weight of the locomotive, stated to be 42 tons, is nearer three times that amount. This, however, is not an error of primary importance, as the weight of any experimental engine—the first of its kind—is always nearly double what it may be worked down to with a little experience.



Side View (Section) of Circular Valve—Exciter Engine, Heilmann Locomotive.

Whilst writing you on the subject, it may be of interest to draw more special attention to the very neat form of high-speed vertical engine employed to drive the exciter

Digitized by Google

dynamo. The valve arrangement, as may be seen from the accompanying illustrations, is of peculiar pattern, having a circular shape, and being practically self-adjusting for surface wear.

This engine has two cylinders side by side, each 6in. diameter, with 6in. stroke; the cranks are set at 180deg. apart; the speed, as stated, is 300 revolutions per minute. For an open engine, with no special arrangements for lubrication, etc., the running at this speed appears to be all that one could wish. Of course the output is small—not more than about 16 kilowatts—and doubtless the steam consumption would be heavy even with the cut off at 50 per cent. A centrifugal governor on the flywheel serves otherwise to regulate the speed.—Yours, etc.,

FRANK B. LEA.

PRACTICAL INSTRUMENTS FOR THE MEASUREMENT OF ELECTRICITY.

BY J. T. NIBLETT AND J. T. EWEN, B.SC.

(Continued from page 71.)

RESISTANCE, *continued.*

Wheatstone's Bridge with Earth Return.—When it is desired to measure the resistance of any conductor, such as a telegraph wire or cable, for instance, where it would be impracticable to connect up both ends to an ordinary Wheatstone's bridge, advantage is taken of the earth as a conductor, and connection is established through it. Its great size renders the resistance of the earth practically nil, and therefore its potential at all places may be taken as the same. Potential, like temperature, being a merely relative term, its zero—as has been done in the case of temperature—may be selected arbitrarily; and it is found most convenient to take the potential of the earth as zero, so that potentials higher than that of the earth are termed positive, and those lower, negative. Thus if any point in a circuit be directly connected with the earth, the potential of that point is at once reduced to zero, provided the earth connection is made without any sensible resistance—an important consideration.

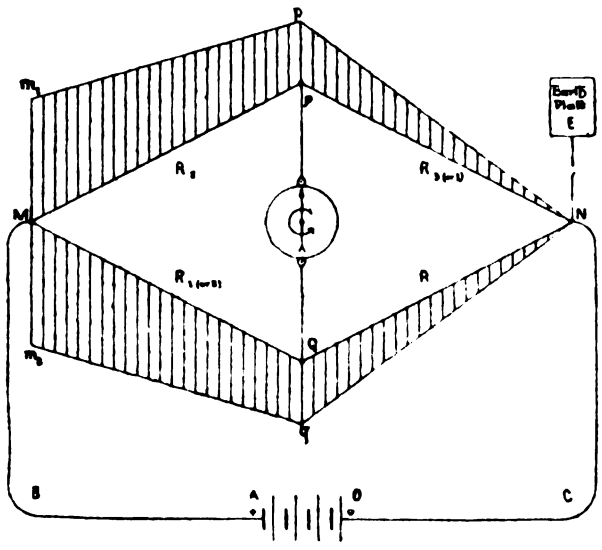

FIG. 42.—Wheatstone's Bridge Circuit (closed), with Earth Connection.

To illustrate the principle involved in the application of an earth return to a Wheatstone's bridge, let A B M $\frac{P}{Q}$ N C D, in Fig. 42, be the divided circuit, in which A and D are the positive and negative poles of the battery or other current generator, and M P N and M Q N are the two arms of the bridge, with a galvanometer interposed in the usual way between the two points P and Q. M P and P N respectively represent the ratios R_2 and R_3, M Q is the known variable resistance R_1, and Q N is the resistance being measured, R. Or, since R is $= \frac{R_1 R_3}{R_2}$, we may interchange the positions of R_1 and R_3 as indicated in the figure, so that M P and M Q represent the ratios, and P N the known variable resistance, Q N representing, as before, the unknown resistance. This is indeed the most usual arrangement in testing sets, one pole of the battery being generally connected between the two ratios R_2 and R_3.

Let now the point N be connected to earth by means of the earth-plate E, as shown. Then the potential at N and at the negative pole, D, of the battery at once become zero, and the diagrams of potential for the two arms of the bridge will be of the type shown by the two vertically-shaded figures. In these figures the potential at any point in M P or P N is represented by the vertical height of the diagram above that point, while potentials of points in M Q and Q N are measured vertically downwards. Thus the potential of M is represented by Mm_1 or Mm_2, which, of course, are equal; the potential at P is represented by Pp, and at Q by Qq, while at N the potential is zero. The difference of potential between any two points is represented by the difference in height of the figure or figures at the two points. It will be seen that the operation of measuring the value of R is in nowise altered by the introduction of the earth-plate at N, and consists, as before, in so altering the relative values of R_1, R_2, and R_3, that the heights Pp and Qq of the potential diagrams at P and Q are exactly equal, in which case the galvanometer needle will show no deflection, and we shall have, as before,

$$R = R_1 \times \frac{R_3}{R_2}.$$

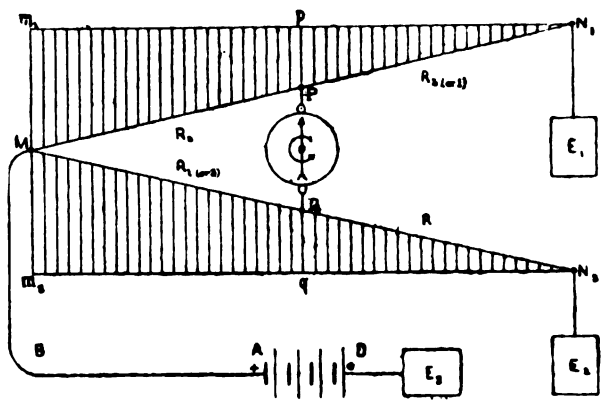

FIG. 43.—Wheatstone's Bridge Circuit (opened), with Earth Connections.

But since the potential of the earth is the same at all places, as we have already seen, the conditions of the test will not be altered, although the three conductors which are shown meeting at N in Fig. 42—namely, R_3 (or 1), R, and the negative pole, D, of the battery—are all separated, as illustrated in Fig. 43, provided each of them is efficiently connected to earth as indicated. The diagrams of potential will be represented by the vertically-shaded figures shown in Fig. 43, which are precisely similar in character to those in Fig. 42, and the galvanometer will show no deflection when the heights Pp and Qq are equal as before, in which case we shall again have

$$R = R_1 \times \frac{R_3}{R_2}.$$

In practice it is usual to make one earth-plate serve for connecting to both N_1 and the battery pole D, thus fulfilling the functions of E_1 and E_3; while N_2, the further end of the cable or wire under test, is generally at a considerable distance, and is connected to a second earth-plate, E_2.

(To be continued.)

THE THEORY AND DESIGN OF THE CLOSED-COIL CONSTANT-CURRENT DYNAMO.*

BY HENRY S. CARHART.

(Concluded from page 176.)

Quoting again from Prof. Ryan: "The air-gap is made of such a depth that the ampere-turns required to set up the magnetisation through the armature, without current,

* Paper read before the Franklin Institute, December 26, 1893.

Digitized by Google

and for the production of the highest E.M.F. that the machine will be called on to give, shall be a little more than the armature ampere-turns when it furnishes its normal current. Then as long as the brushes are kept under the pole faces, the non-sparking point will be wherever the brushes are placed. This will be the case whether the armature is or is not saturated." Again: "The impressed field ampere-turns are in excess of the armature ampere-turns by that amount which is just sufficient to produce a weak positive field that will reverse the current in the coil when its terminal bars at the commutator pass under the brush." This latter statement appears to be borne out by the data given, but the machine experimented upon was one giving a maximum of only 35 volts and 22 amperes, and its performance can scarcely be considered a sufficient guide for the design of machines required to furnish several thousand volts and a current of from 9·5 to 10 amperes. Again, I have known a 40-light machine converted into a 50-light without any change in the field whatever. The armature either contained more iron, or was wound with a larger number of turns of wire. Both methods have been followed without effect on the sparking. The first method leaves the armature ampere-turns the same; the second increases them 25 per cent. If the relation pointed out by Prof. Ryan holds in the first armature, it cannot also hold in the second with such a material increase in armature-turns.

Further, if this relation does hold, there still remains unanswered the question of relative cross-section of iron in armature and field. Shall the core of the armature be saturated or not? Mr. Esson says that 17,000 lines per square centimetre is the best practice in England for constant-potential machines.

I know of one constant-current machine in which the armature core is forced well up toward the highest saturation obtainable in a dynamo machine. It is able to produce very high E.M.F., but it does not govern sparklessly by means of a single pair of brushes. Two other types of machine of which I have data work with about 11,000 lines per square centimetre in the armature. In both of these recent changes are along the line of increasing iron and decreasing copper in the armature. I have explicitly advised the use of more iron in the armature for two years. One manufacturer recently told me that he is now following my advice with most gratifying results. With the same number of turns on the armature the output is greatly increased. To what extent the iron in the armature can be increased is an open question. It has now been carried beyond a cross-section equal to 75 per cent. of the wrought iron in the field cores. If increased cross-section of the core introduces sparking, this can be avoided by increasing the number of bars on the commutator, so as to decrease the self-induction in the section under short-circuit by the brush. Indeed, if the output is kept the same, increase of iron decreases turns of wire, and to that extent decreases self-induction. In a machine with two pairs of brushes, the effect is to diminish the angular embrace of each pair.

It is interesting to compare two machines of almost exactly the same capacity, but differing widely in relative core section and armature-turns. Let the two machines be represented by A and B. The data of the two are given in the following table:

Machine.	Total volts.	Revs. per min.	Segments in commutator.	Turns per segment.	Total turns.	Cross-section of iron, sq. in.	Lines per sq. in.
A.....	2,900	1,000	132	36	4,752	26·5	70,800
B.....	2,800	875	120	72	8,640	14·0	79,000

The maximum number of lines of force running through the armature of the A machine is 3,650,000; of the B machine, 2,213,000. The two machines are designed for the same current of a little under 10 amperes. The ratio of the ampere-turns on the armatures of the two is nearly inversely as the cross-section of their iron cores. The ampere-turns on the B armature is 82 per cent. greater than on the A armature. It is not probable that the field ampere-turns on B is 82 per cent. in excess of those on A. Unfortunately those particular data are lacking, but the magnetic circuit of A is quite as good as that of B. It does not appear at all probable, therefore, that Prof. Ryan's rule applies to both machines. It is gratifying to our national pride that American designers have successfully carried the Gramme ring constant-current dynamo to an output far beyond what some foreign electricians with more theory and less practice in this direction still declare to be impracticable. The writer of a series of articles in the London *Electrical Review* says: "Beyond about 1,000 volts it is found, in general, to be impracticable to work a closed-coil armature, for either there will be a wasteful lead, or there will be vicious sparking under the brushes, or the current will flash from strip to strip, and will destroy the commutator. . . . . It seems more than probable that machines of this kind will not stand any serious alteration of load if worked at higher voltages, owing to the great range of lead which would be required, and the consequent sparking and flashing over." Again he says: "There is of necessity a large armature reaction in certain forms of arc light machines, and when this is the case, the brushes would require to be shifted right into the centre of the pole arc before sparking would cease, if there were very many turns on each section. The wastefulness of this practice consists in the large number of back-turns and cross-turns which it involves." But in the face of such declarations as these, a large number of American machines are now running at an output of 9·6 amperes, and from 5,000 to 10,000 volts. A very considerable number of closed-coil Gramme rings, giving 5,000 volts, are in actual use without breakdown and without any of the fatal drawbacks predicted by the writer quoted.

The design of closed-coil Gramme rings for high-potential arc lighting has thus far been limited to the two-pole type of field magnet. This involves the maintenance of higher speeds than engineers find desirable. The conditions of present practice and the requirements for the immediate future demand a new departure in this class of dynamo design. All indications point toward a multipolar machine of about 50 kilowatts capacity and slow speed. The armature will contain a liberal amount of iron, much larger than would be found desirable for constant-potential machines. Such a dynamo is already in demand, and it will find an immediate field for the lighting of large cities.

INSTITUTION OF ELECTRICAL ENGINEERS, Feb. 22.

Mr. Alex. Siemens, President, in the chair.

At last night's meeting of the Institution the following candidates were balloted for:

Foreign Member.—Knud Bryn, Central Telephone Station, Christiania.

Members.—Benjamin Walter Deakin, 2, Raeburn-street, The Avenue, Brixton, S.W.; George William Locock, 2, St. James-square, Manchester.

Associates.—Henry Abrahams, Faraday House, Charing Cross-road; Edward Neville Bray, Manor House, Shere, Guildford; Alfred Collyer, McGill University, Montreal; Thomas W. Ellison, 82, Weinbergstrasse, Zürich, Switzerland; William Eversley Hardy, Park View, Alexander-road, Norwood; George William Hodder, St. Aubyn's, South Lowestoft; Chas. Henry Blackwood Longworth, McGill College, Montreal; Charles Picton Martin, 66, Victoria-street, Westminster, S.W.; John Willoughby Meares, Clive Hall, Shrewsbury; John William Morris, Wallace, N.S., Canada; John Walker Parr, "Wonham," Worsley-road, Hampstead; Evan Parry, 52, Glengarry-road, East Dulwich, S.E.; Gerard S. Peek, 11, Pavilion-square, Scarborough; Frank Henry Pitcher, 767, Wellington-street, Montreal; H. B. Price, The Arc Works, Chelmsford; Alexander Brodribb Randall, Archer's-road, Southampton; William Seymour, 94, Walton-street, Lennox-gardens, S.W.; Hilliard S. Stephens, 1, Wellington-chambers, Westminster, S.W.; James Roberts Sykes, jun., 15, Garville-avenue, Rathgar, Dublin; Lieut Oswald T. O. K. Webber, R.E.; Gilbert Winslow, B.A., "Crake Hall," Wimbledon Common, S.W.

Students.—Henry Chas. Ashton, 6, Ashmore-road, Harrow-road; Chas. Frederick Haswell Bayly, Moreton House, Kentish Town-road; Ernest E. Benham, 26, Church-gate, Loughborough; Leonard Harry Combe, Faraday House, Charing Cross-road, W.C.; Kenelm Edgcumbe, 33, Tedworth-square, Chelsea, S.W; Herbert Tyndale Haws, 29, Gladstone-road, Croydon; C. F. Hesketh, Penywern House, Earl's Court, S.W.; Leonard Johnstone, 3, Katharine-street, Croydon; Gustave Lemmens, High View, Anerley-road, Upper Norwood; G. P. Roy, the Royal Indian

Engineering College, Cooper's Hill; Percy S. Sheardown, 107, Mildmay-road, N.; R. Valle, Penywern House, Earl's Court, S.W.; Harman Wigan, Cromwell House, East Sheen; J. G. Wilson, B.A., Penywern House, Earl's Court, S.W.; Thomas Parry-Osborne Yale, Faraday House, Charing Cross-road, W.C.

The following paper was then read:

ON METHODS OF TESTING THE MAGNETIC QUALITIES OF IRON.

BY GISBERT KAPP, MEMBER.

The industry generally comprised under the term "heavy electrical engineering" has of late years made such rapid progress that the question as to the kind of materials to be used has become of great importance. As regards the copper wire required in the construction of electrical machinery, certain standards regarding the size and conductivity have from the very first been adopted. The metal of commutator plates, size of wearing surface, type and number of brushes, dimensions of resistance coils, and other purely electrical parts of the machinery, have also, as a rule, been specified; but as regards the iron used no attempt was at first made to define it by specification. Makers of dynamos, for instance, broadly distinguished between cast-iron and wrought-iron field magnets, and got out their designs with reference to the magnetic properties each of these two kinds of iron was assumed to possess; but there was no certainty that the iron obtained did actually possess these properties. If the machines turned out according to design, well and good; if not, then the speed or excitation had to be altered so as to get the output right. This was the old and unscientific method of building electrical machinery. The modern method is very different, and far more certain. The manufacturer of a dynamo knows exactly what kind of iron he is using, and he is thus able to predetermine the performance of the machine with a degree of accuracy which formerly was impossible. This is especially of importance in large machines, as experimental runs to determine the characteristic at full load are not easily made, and are always expensive. In such cases it is preferable to cut a sample from the magnets, test it magnetically, and use the results of this test in designing the winding.

In some cases it is not even necessary to cut off samples and test them, as the manufacturers of forgings and castings for magnets offer now to supply these so as to conform to a certain magnetic standard, commonly defined by means of a curve in which the abscissæ represent magnetising force and the ordinates induction. Provided, then, the ironmaker supplies exactly the material which he has promised, the winding of the machine can be designed without any preliminary experimenting. Ironmakers are now keenly alive to the importance of this subject, and produce most excellent material. The testing of iron plates intended for use in alternators and transformers is another of those questions which had to be faced by manufacturers who wished to attain perfection in their work. As regards transformers, it will probably be admitted by all that the quality of the iron is the most important factor in the whole design. To make a good dynamo with inferior iron is still possible. We need only use enough of it, and spend enough money on the copper to make up for the deficiency in the iron. With transformers this cannot be done. If the iron is bad, no increase in its bulk, and no amount of money we may spend on copper, will enable us to turn out a good transformer. The important point with transformer plates is not the higher or lower permeability, but the waste of power by hysteresis and eddy currents; although to a certain extent the two go together, in the sense that a very soft iron having high permeability also has, as a rule, a small hysteresis loss. Plate-makers, recognising the importance of small hysteresis, now offer their material with a guarantee that the loss with a given induction and frequency shall not exceed a certain amount per pound.

Admitting, then, the necessity for magnetic tests of iron, the question as to method arises. There can be no doubt that the methods adopted by Dr. Hopkinson and Prof. Ewing in their classical researches give the most accurate results; but the very perfection of these methods forms a drawback to their adoption in engineering works where highly-trained experimenters cannot be found. I have therefore adopted other methods, which do not aim at absolute accuracy, but which can be used by any one of the staff generally found in the test-room of electrical engineering works. The apparatus required is on the table, and I venture to bring it before you because it has been in use for some years, and has given results which were always found sufficiently accurate for all practical purposes. It will be convenient to divide the subject into two parts—one dealing with the testing of magnet iron, and the other with the testing of transformer plates.

Testing-machine for Iron Bars.

This is shown twice full size in the wall diagram. For the principle on which it is based I am indebted to a little instrument devised some four years ago by Prof. Silvanus Thompson, and called by him a "permeameter." In it the induction through the sample bar is measured by the force required to pull the bar away from another piece of iron, and as the induction is proportional to the square root of this force, it is clear that any small error in the measurement of this force results in a still smaller error in the determination of the induction. Thus, if his spring balance were wrong by 2 per cent., the error in estimating the induction would only be 1 per cent. So far, then, as the determination of B was concerned, the permeameter appeared to be an exceedingly accurate instrument, but this alone is not sufficient. We must have the relation of B and H, and, as part of the total ampere-turns applied is required for the magnetic circuit outside of the sample, certain corrections must be applied in the determination of H. It was mainly with the object of making these corrections both small and definite that I altered the design of the Thompson permeameter and made it in the form shown on the diagram. The instrument consists of a heavy rectangular frame, made of the best Lowmoor iron, well annealed. Within the frame is fixed a solenoid with subdivided winding, so that a variable, but known, number of turns can be placed in circuit by using the various terminals provided on the instrument. The object of this arrangement is to keep the current within such limits as will ensure the greatest accuracy in its measurement, whilst the magnetising force is varied between very wide limits. A reversing switch is inserted to facilitate the investigation of the complete cycle.

The sample consists of a bar accurately turned and faced at the lower end. The bar is kept larger at the upper end, where it passes through a hole in the frame—a fairly tight fit—and it is centred near the lower end by a little gunmetal ferrule. Below the bar is a soft iron plunger, guided in a hole in the frame, and provided with an attachment for holding a scale-pan and weights. The plunger is made larger than the bar, and has a fine hole drilled through it to ensure good contact over the rest of the surface. The dimensions of the plunger and the hole in the frame being accurately measured, it is of course quite easy to determine by calculation how much of the ampere-turns provided is required to overcome the resistance of the annular air-space; and this is the only important correction required. The other corrections—such as the magnetic resistance of the frame, or that of the joint between the sample and the frame at the top—are quite trifling. Even the correction for the resistance of the air-space is only important for low inductions. For inductions above 10,000 it becomes relatively small, and above 15,000 quite negligible. The method of using the instrument is as follows: The sample, with its end carefully faced, is inserted from the top, and a small current sent through the solenoid, using the smallest number of turns. The plunger flies up against the sample and sticks there. The scale-pan is attached, and weighted until the plunger comes off. The exact point at which the weight overcomes the magnetic attraction is best determined by slightly varying the current by means of a rheostat; and I may mention that it is necessary to use a storage battery to provide the current. To work directly from a dynamo is impossible, as the slight variation in current produced by the irregularity in speed of the engine, or the flicking of a belt, is quite sufficient to make the tearing-off point uncertain. The current, number of turns in the solenoid, and the weight are now increased step by step, then decreased again to zero. The current is then reversed, and the operation repeated, so as to obtain the complete cycle. The values recorded are ampere-turns and tearing-off weight, in which is, of course, included the weight of the plunger and scale-pan. The greatest weight supported by a ¼in sample bar of good iron is about 45lb. I need not detain you by giving in detail the calculations for finding the relations between ampere-turns and H, or weight and B, nor the values of the corrections,* since these are purely elementary matters, and can be worked out for any testing-machine of this type if its dimensions are known. The time occupied in testing a sample through a complete cycle is about an hour; one man manipulating the weights, and the other the current. The latter also books the readings.

I have used the apparatus before you in testing large numbers of samples of cast iron, wrought iron, and mild steel submitted to me for investigation by different ironmakers, and some of the curves obtained are on the table. For obvious reasons I do not mention any particular maker of magnet steel; but I may say generally that the samples of steel submitted to me were very good, and in some cases better than wrought iron. The good qualities of mild steel as revealed by the testing machine were fully confirmed when the same material was used in dynamos, and thus tested on a large scale.

Testing-machine for Transformer Plates.

My first attempt to make such a machine was a failure, but as failures are sometimes as instructive as successes, I have placed the machine on the table for your inspection. In this machine I did not measure the power lost in the sample, but endeavoured to get an approximate means for comparing the permeability of different samples. An iron ribbon is coiled up to form a closed ring, and this is wound on opposite sides with coils so connected as to produce consequent poles over the two sides kept free from winding. The sample is made up of narrow strips into a flat bar, which is laid across the poles to form a magnetic bridge. The sample is surrounded by a pilot coil, and this is connected with an electrostatic voltmeter. If the same current is always sent through the main coils, and at the same frequency, then the volts produced by the pilot coil are supposed to give, roughly, an indication of the comparative value of the samples. The method

* In the instruments exhibited the corrections for top of sample, frame, piston, and air resistance collectively amount to $\frac{2{\cdot}37}{1{,}000}$ B ampere-turns, to be deducted from the total ampere-turns. Thus, for B = 12,000, which would be the lowest induction of practical importance, 28·5 ampere-turns would have to be deducted from a total of about 300; whilst for B = 15,000 the corrections would be 35·5 to be deducted from a total of about 1,500, and for higher inductions the correction becomes quite negligible. If P is the tearing-off weight in pounds, $B = 2{,}973\sqrt{P}$, and if X represents the corrected ampere-turns $H = \frac{X}{20{\cdot}2}$.

Digitized by Google

was a failure, partly because permeability is not an absolutely reliable guide in estimating hysteresis loss, but chiefly because the uncertainty in estimating the magnetic resistance of the joints completely swamped any small differences that might have existed in the permeabilities of the samples. I therefore promptly abandoned this instrument, and set to work on another which would give directly that which we want to measure—namely, the losses at given inductions.

This instrument is shown on the table, and twice full size in the wall diagram. It consists essentially of a closed magnetic circuit of rectangular shape, the two longer limbs being enclosed in exciting coils. One long limb and the two uprights are composed of plates in one piece; the other long limb is formed by the sample plates, which are laid together so as to make up a certain weight, and are then bound together with tape and inserted through the top coil. The sample is fixed by wooden wedges. The coils are connected with a source of alternating E.M.F. through a wattmeter, and the instrument is thus ready for use without further preparation beyond making up a bundle of plates into a sample bar and inserting the latter. The instrument is calibrated once for all by making the sample and the fixed part, or yoke, of the magnetic circuit out of the same quality of plates, measuring the loss of power at different inductions, and apportioning the losses between the yoke and sample according to their weights. When testing other samples the total loss is measured by the wattmeter, and from this is deducted that portion of the loss which is occasioned by the iron which forms part of the instrument, the remainder being the loss in the sample. A correction must be made for the loss of power resulting from the ohmic resistance of the two coils, but this is exceedingly small. The induction is found from the E.M.F. applied to the coils and the frequency. In order to have a wide range of induction, and yet keep the measurements of current and E.M.F. within the limits most convenient for the instruments at hand, the coils are subdivided, and suitable terminals are provided. The resistance of the joints between the sample and the yoke is immaterial, as it influences only the current, but not the power.

The upper curve in the third diagram shows average results obtained in testing samples of plates furnished by several different suppliers of transformer iron. I say advisedly "suppliers," and not makers, because it sometimes happens that the same brand of iron, under different names, is supplied by different iron merchants. In fact, I have had a case in which two samples supplied by rival merchants gave precisely the same curve, and on making enquiries I found that the iron came indeed from the same maker, but was sold under different names. The lower curve shows the results obtained with the best sample I ever tested. As it is not my purpose, and as it would indeed be improper to advertise any particular maker in a paper of this kind, I trust you will not expect me to give his name. The curves are, for convenience in use, plotted under the supposition that the frequency is 100. The abscissæ give induction, and the ordinates loss of power in watts per pound of iron. The thickness of plates varied between 10 and 13 mils. Within these limits I believe that the thickness has only a very small influence on the loss—at any rate, I have not been able to detect any such influence; and this confirms an admirable investigation by Prof. Ewing, in which he showed, on theoretical grounds, that a reduction of thickness below about 13 mils is of no advantage. It is, of course, quite easy to test transformer plates by taking a known weight of stampings and making them up in a transformer with only one coil (preferably a low-pressure coil). If the same coil be always used for this purpose, the results will be perfectly reliable. The method is, however, tedious when a number of samples has to be tested, as time is wasted in building up and taking to pieces again the plates between each set of tests. With my testing-machine all the samples can be prepared beforehand and slipped in quickly one after another, so that the whole series of tests can be performed under the same conditions and by the same men. The facility with which samples can be changed is also of value if it should be necessary to verify any doubtful point in the curve obtained in a previous test.

There is another and very obvious method of testing transformer iron, and that consists in making up a complete transformer with the sample plates to be tested. Apart from the waste of labour entailed if the iron should turn out bad, this method is very uncertain. The reason for this uncertainty is that we test, not the iron alone, but the complete transformer, and we are thus left in doubt as to how much of the measured loss is really due to the iron. Theoretically, the whole loss is due to the iron, but in practice this is seldom the case. When testing a transformer immediately it is completed, and again after some weeks during which it has been regularly at work, you will find that its losses have become less. This I believe to be due to the coils having become thoroughly dry, and their insulation higher. A very small electrical leak in the high-pressure winding may easily lead to a waste of power, which, although small in itself, and not capable of doing any damage, is still appreciable when compared with the true iron loss. Take, for instance, a four-kilowatt transformer wound for 2,000 volts. Its iron loss would be about 2 per cent., or, say, 80 watts. Suppose, on testing this transformer, you find that the loss is not 80, but 100 watts. You might then conclude that the iron has 25 per cent. more loss than it ought to have, and you would condemn the sample. This might, however, be an unjust verdict. The extra 20 watts measured might very well be due to a general leakage of current across the turns of the coil. The leakage surface is large, and the pressure is large, so that the current density of the leak is very small, and no damage will be done. The leak vanishes as the transformer gets dry, and thus may be explained the curious fact that transformers get better after use. The moral of this is that to do justice to a transformer the final test should only be taken after it has been at work for some time.

In conclusion, I wish to express my thanks to Messrs. Johnson and Phillips for the loan of the testing-machines here exhibited.

DISCUSSION.

The discussion was opened by **Prof. D. E. Hughes**, who pleaded that he possessed no such great experience of testing the inductive qualities of iron as to qualify him to speak with authority. With the small instruments and appliances used in telegraph and similar work, he had found it most essential to secure great exactness in all the measurements. Of course, with the large powers involved in dynamo and transformer work such exactness was not so much required. Mr. Kapp's method seemed to him to have much to recommend it.

Prof. S. P. Thompson felt obliged to say that although Mr. Kapp had put his device in its first form to good practical use, yet he himself had also made considerable improvements in it, so much so indeed that its later form was to his mind even better than that employed by Mr. Kapp. The most recent type which he had used was constructed with a mass of iron surrounding the coil, having a cross-section not less than 200 times that of the test piece. The latter was the plunger itself, and was made much longer and thinner to eliminate sources of error due to magnetic reluctance. With regard to the transformer iron tests, he thought that the corrections which were necessary would vary considerably at different degrees of saturation. Prof. Thompson then went on to give the results of researches he had made upon the behaviour of large masses of iron serving—*e.g.*, as yokes in instruments or machines, and detailed some extremely interesting conclusions to which he had been led. For instance, in the case of a large sheet of good soft iron—large enough to be regarded practically of infinite area in comparison with the rest of the appliance—and not less than 10mm. thick, he had found it to act in all respects as a magnetic mirror. By placing a coil near such a plate he found that the latter acted as though it doubled the action of the coil, and by setting two such plates parallel with a coil between them, he obtained an effect similar to that given in optics by a like arrangement of glass mirrors—an endless coil in the one case, just as an endless image in the other. Prof. Thompson finally made a suggestion for measuring the inductive qualities of iron by means of an ebonite plate containing thin flat coils—entirely separated—placed between two blocks or masses of the metal to be tested.

Mr. Steele stated that a long series of tests had been made at Johnson and Phillips with strong steel and iron used in transformers and dynamos, and that the instrument devised by Mr. Kapp had yielded very accurate results. Two hours only were required in making and testing a sample.

Dr. Fleming observed that the paper was exceedingly important from the point of view of makers and of central-station people. Whilst the author's instrument might become extremely valuable, unless one had an opportunity of comparing the results of testing samples of iron with his instrument with those of the samples when made up in transformers, one would hesitate to accept them. Had Mr. Kapp tested them?

Mr. Sparks remarked that the results obtained with small samples cut from one sheet greatly varied, and marked differences were noticeable in one ton and in another ton of iron.

Prof. Perry informed Dr. Fleming that if he wanted pure iron, he should ask the cast-iron makers of Sheffield, who supplied real charcoal Swedish iron.

Mr. Mordey, who congratulated the author, said there was no more important question at the moment than that of getting good iron. The Brush Company had established a specification for the iron makers, and that answered well.

The **President** having made a few observations, the author replied to the discussion, and a vote of thanks to Mr. Kapp concluded the proceedings.

ELECTRIC SIGNALLING WITHOUT WIRES.*

BY W. H. PREECE, C.B., F.R.S.

What is electricity? Few venture to reply boldly to this question, first, because they do not know; secondly, because they do not agree with their neighbours, even if they think they know; thirdly, because their neighbours do not agree among themselves even as to what to apply the term. The physicist applies it to one thing, the engineer to another. The former regards his electricity as a form of ether, the latter as a form of energy. I cannot grasp the concept of the physicist, but electricity as a form of energy is to me a concrete fact. The electricity of the engineer is something that is generated and supplied, transformed and utilised, economised and wasted, meted out and paid for. It produces motion

* Abstract of paper read before the Society of Arts on Feb. 21.

of matter, heat, light, chemical decomposition, and sound; while these effects are reversible, sound, chemical decomposition, light, heat, and motion reproduce those effects which are called electricity. Faraday's immortal researches, Clerk Maxwell's prophetic investigations, and Hertz's convincing experiments, have definitely and conclusively proved the existence of one medium throughout all space, called the ether, through which waves of energy, called radiations, are propagated with the same velocity, but in different forms and with different frequencies, although all of the same character. At one end of the scale we have actinic disturbances producing photographic impressions; at the other end of the scale electric waves producing elec tromagnetic disturbances, while the intermediate radiations give light and heat. Actinic waves are extremely minute, and number many millions per second, electric waves are very long and may number only hundreds per second. Like light waves, they are propagated in straight lines, they obey the laws of reflection, they are refracted, they are subject to interference, and they may be even polarised.

We have to consider electric waves to-night, and I want to show you how we are gradually, by patient plodding, creeping along towards the period when I hope we shall be able to make real practical use of such electromagnetic disturbances. If we take a conductor through which a rapidly alternating current is being supported by any means, it throws the ether which surrounds it into oscillations. Energy is thus radiated away in electric waves. These electric waves spread out in all directions, as do waves of light, and if they fall on similar conductors properly placed and sympathetically prepared, these waves of energy are transformed back again into alternating currents which give evidence of their presence. Their presence is indicated by a telephone if the frequency of the alternating currents is brought within the range of the ear. Hertz and his followers experimented with waves of much shorter length, and with sparks in air, but all my experiments have been made with telephones and with waves comparable in frequency with those of sound. The prime source of energy has been either a steam-engine or a galvanic battery. This has produced, by suitable machinery, rapidly intermittent or alternating currents, which have been transmitted through a primary circuit. At some distance away from this circuit there has been a secondary telephone circuit, and between these two circuits the only connecting medium has been the ether, which has been thrown into electric oscillation, and it has been across this space that I have been signalling without wires. In all cases, the primary currents were of such a frequency as to produce a musical note in the telephones fixed in the secondary circuit, which could easily be read, if sent in the dots and dashes of the Morse code. Signalling through space is very fascinating. I have now for 10 years been steadily investigating the subject.

[The author then referred to experiments made in this direction by himself and by others on his behalf. The results of these experiments were given in a paper read by Mr. Preece "On the Transmission of Electric Signals through Space," before the Electrical Congress at Chicago on August 23, 1893. This paper, together with illustrations, was reproduced in the *Electrical Engineer* of August 25 and September 1, 1893, and to which we refer our readers.]

As the laws governing these effects [those observed in the case of the experiments referred to] were by no means so clear and conclusive as such probing and enquiring deserved, Mr. Gavey and Mr. Kempe conducted for me a very careful series of experiments near Frodsham, on the estuary of the Dee, which was found to be a more convenient locality than Conway, and the very satisfactory results obtained will shortly be published. The conditions are now so clear that, given the localities between which it is desired to communicate, it is a mere matter of calculation to show what has to be done. It would be quite easy to speak between France and England across the Straits of Dover. There happens to be a convenient and accessible loch in the Highlands — Loch Ness — forming part of the route of the Caledonian Canal between Inverness and Bannavie, having a line of telegraph on each side of it. Five miles on each side of this loch were taken and so arranged that any fractional length of telegraph wire on either side could be taken for trial. Ordinary and not special apparatus was employed, sending messages, as before, by Morse signals, and speaking by telephone across a space of one and a quarter miles was found practical, and, in fact, easy; indeed, the sounds were so loud that they were found sufficient to form a call-for attention. The following apparatus was in use on each side of the loch for the transmission of Morse signals: A set of batteries, consisting of 100 dry cells, giving a maximum voltage of 140; a rapidly-revolving rheotome, which broke up the current into a musical note; a Morse key, by which these musical notes could be transformed into Morse signals; resistance coil and ampere-meters to vary the primary current; two Bell telephones joined in multiple arc to act as receivers. For the transmission of actual speech simple granular carbon microphones, known as the Deckert's, were used as transmitters, and a current of two amperes was maintained through these and two Bell telephones in circuit with the line wire. Any lingering fear that earth conduction had principally to do with these results was removed by making the earth's terminals on the primary circuit at one end at Inverness nine miles away, and at the other end in two directions in a parallel glen about six miles away. The early experiments of 1886, in the valley of the Severn, had placed this question of earth interference beyond the region of doubt, but earth conduction, as a main factor in the results, is still believed in by critics. The function performed by the earth has been thoroughly developed in the Frodsham experiments, and will be discussed subsequently.

One very interesting fact observed at Loch Ness was that there was one particular frequency in the primary circuit that gave a decided maximum effect upon the telephones in the secondary circuit. This proves the presence of resonance, and is, of itself, a fact sufficient alone to prove the effects as being due to the transformation of electric waves into electric currents. It is well known that every telephone has one particular note—the natural note of the disc—to which it responds better than to any other, but this resonant effect far exceeded in magnitude any difference due to the natural pitch of the disc. It was not the natural note. Conversation by telephone, though possible, was not, however, practical. Still, it is something to have transmitted speech by electricity across an air-space of 1¼ miles. We had this curious condition, that at some intermediate point the energy of the human voice was found side by side in two different forms—sonorous vibrations in the air, and electric waves in the ether. There is now no difficulty in communicating with outlying islands if the conditions are favourable. The Northern Commissioners of Lights are anxious to establish electrical communication with the Muckle Flugga lighthouse, at the extreme north of the Shetland Islands, but the place is so inaccessible that, though the conditions are favourable and signalling without wires is possible and simple, it would be more prudent to adopt the more expensive plan of a submerged cable. I would rather inaugurate the system nearer home, where it could be watched, nursed, and improved. Anyhow, it is something to be able to report that we have now acquired a practical system of signalling across space without the necessity of using wires.

Although this short paper is confined to a description of a simple practical system of communicating across terrestrial space, one cannot help speculating as to what may occur through planetary space. Strange, mysterious sounds are heard on all long telephone lines when the earth is used as a return, especially in the calm stillness of night. Earth currents are found in telegraph circuits, and auroræ borealis light up our northern sky when the sun's photosphere is disturbed by spots. The sun's surface must at such times be violently disturbed by electrical storms, and if oscillations are set up and radiated through space, in sympathy with those required to affect telephones, it is not a wild dream to say that we may hear on this earth a thunderstorm in the sun.

SOME NOTES ON THE ELECTRIC LIGHTING OF THE CITY OF LONDON.*

BY MAJOR-GENERAL WEBBER, R.E., C.B.

(Continued from page 204.)

Distribution.

Outside the postal telegraph and the city engineer's offices there was no one who could form any accurate idea of the condition of things below the surface of the City streets. The subways in Victoria-street, in Arthur-street, and in the Holborn-viaduct, although suitable for through mains of supply of any kind, were eminently not so for electric distribution conductors, which have to be tapped at frequent intervals for the supply of current for public and private lighting. Although forced to use them, the cost of such mains and services to a supply company is higher than if the lines were laid under the footway on either side.

In March, 1890, the London County Council, with the approval of the Board of Trade, and the confirmation of the Home Secretary, under the terms of the Metropolitan Subways and Government Acts of 1868 and 1888, had published by-laws for regulating the use of subways. These, while in force in the Queen Victoria-street subway, are not so in those under the Holborn-viaduct and Arthur-street. Anyone who has used street subways for electrical conductors in common with gas, water, and other companies, will understand that, except for primaries, the electrical engineer would much rather remain outside. The by-laws are excellent for the regulation of this user, but the panacea, which excellently-intentioned persons believe exists in street subways falls short of theirs and the public's expectations. The law allows the local authority to oblige us to use them where they exist, and to charge us a rental for that use; but as the word "pipe" in the Act includes a "tube for wires," and as the rental, irrespective of the number of wires, is £16 per annum for a 3in. pipe for the 1,200 yards of the Queen Victoria-street subway, and £49 per annum for one under 18in. diameter for the same length, the way-leave is not very costly, but the cost of using it is extremely so. Sections of some of the subways, with the conduits placed in each for electric light conductors, are shown. In each case, the obligation to use the subway instead of the ground under the footways entailed one excessive expenditure common to both—namely, the works in breaking through the massive arches and deep cuttings in the roadways to get at the street lamps, and, in many places, to obtain access to the houses, in some places 30ft. away. In the Arthur-street and Holborn-viaduct subways a large number of "ways" in Callender-Webber casing have been secured at a very little cost. In the Queen Victoria-street subway, cast-iron troughing on wall brackets, as first designed, proved an awkward and costly arrangement in many ways; the weight of the structure was nearly 3cwt. per yard. Lighter troughing designed by me was adopted, of which follow sections. The trough contains cables—six of 1·9in. external diameter, three of 1·5in. external diameter, and four of 0·7in. external diameter;

objections to working in such subways (apart from maintenance) are (1) the difficulties, physical and otherwise, of access to them, both for *personnel*, material, and plant; (2) the delays to work, due (*a*) to defective lighting, (*b*) time required to communicate with the authority and other occupiers, (*c*) to foul atmosphere; (3) the engineering obstacle due to the works of previous occupiers, and to the cutting in and out where necessary to reach side streets.

My own postal telegraph experience in 1871 and 1872 had been in the difficult ground in thoroughfares like Cornhill; and although in 1891 and 1892 places were come upon where hardly a single conduit could be laid, the task, owing to the system adopted, proved, on the whole, less difficult than was anticipated; and, as was expected generally, the thoroughfares running north and south were easier than those east and west, for the reason that most water, gas, and telegraph mains tend from the City towards outside centres in those directions. The pioneer work included the opening of certain main thoroughfares, so that the arc lighting might be got forward. In these, the most thronged streets of the City, it was essential not to have to repeat the inconvenience of opening the ground. Whatever was laid down at the first operation had to form a portion of, and suffice for, the completed scheme. In a matter so long under my own consideration I had no hesitation in recommending that sufficient conduit accommodation should be provided, and that it should take the following form—viz.:* (*a*) iron pipes for concentric high-tension mains from the generating to the transforming stations; (*b*) iron pipes for continuous-current high-tension mains for the public arc lighting; (*c*) bitumen concrete casing for three ways, to accommodate the conductors of a low-tension distributing system, both feeders and distributors.

The future needs of the great whole had, as I shall describe further on, to be thought out before March of 1891, so that each part of the work, however preliminary, should eventually fit in to the permanent system. The future need for spare conduits, possibly for telephones, had also to be thought of, and it was provided for as far as the very limited space under the footways of those thoroughfares which were first treated would permit. The question of interference, through the neighbourhood of alternating-current working, with telegraph and telephone circuits was at that time under public discussion. I had very little time, and had to be satisfied with one experiment having the object of observing the screening effect which was anticipated would exist through the interposition of what might be called "faggots" of iron pipes, lying in the same trench as the non-conducting conduits, into which the low-tension distributing mains were to be drawn. For the experiment, conduits and pipes were laid on trestles under nearly the same conditions as in the trench, and a 200-volt current with 100 frequency (obtained by transformation) and 100 amperes was passed through two of the three ways of a bitumen

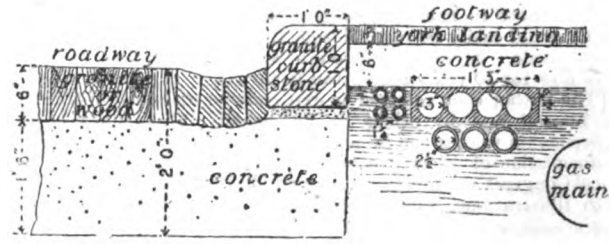

FIG. 9.—Sections of Road.

concrete conduit in conductors having a sectional area of copper of about one-tenth of an inch. Telephone circuits with metallic† returns laid parallel were tried. The iron tubes were placed at various distances and in various numbers. Imperfect as the trial was, it gave us security that at a distance of 12in. from the Callender-Webber casing, twin telephone circuits in iron pipes would be fairly secure from trouble. But, as an additional precaution, it was decided to sheath the casing with iron. Within a distance of about 6in. a very slight disturbance could be still heard. A sample of casing thus treated is on the table amongst the other samples illustrated.

The choice was further justified, because the Duke of Marlborough, with his usual foresight, asked several practical engineers to meet him in a friendly way soon after this advice had been given and adopted, in order to discuss the whole question. From my notes of that meeting, held on March 23 and 24, 1891, I find the conclusions then come to coincided with the system above referred to, which was already in course of execution. Those present at this meeting were the Duke of Marlborough; Messrs. T. Callender, Gordon, Gray, Heaviside, Mavor, Raworth, A. Siemens, Wharton, and Major-General Webber. It is not to be assumed that unanimity on matters of detail was expected or arrived at. As regards anticipated electrical troubles, the avoidance of interruption of telegraph and telephone circuits was the only thing dealt with at those consultations. Those present had till then had, I must presume, no practical experience of the

* The entire responsibility of thus advising the pioneer company rests with me. As the pioneer contracts (with the making of which I had nothing to do) had only provided conduits sufficient for the cables from the pioneer generating stations, and had specified nothing as regards the underground conditions, it was necessary, in order to prevent the consequent waste of having to excavate the same ground twice, to make additional provision. And as the isolated areas treated by these pioneer contracts had to be considered as forming a part of the great whole, the whole of the details of the completed work had to be gone into.

† Experiments made in 1880 with telephone circuits with and without earth returns, between Paddington and Westbourne Stations, laid in the same wooden troughs as 40 or 50 working single and double current telegraph circuits, saved me from having to make any trial with earth return for the telephones.

Digitized by Google

resistance due to skin effect, or self-induction, in the case of single conductors of over one-third of an inch section of copper used to convey alternating currents at low pressure. The use of concentric lead-covered cables laid in the earth, with iron split-tube protection where joints have to be made, was discussed with the advocates of that system as used in Germany, and its advantages, both as to reliability, manageability, and first cost, in comparison with two or more highly-insulated conductors in one iron pipe, were weighed, especially in view of the claim that, wherever laid, it is everlasting. The question of influence on telegraphs and telephone, and the means of screening or damping down the magnetic field, was discussed, and various experiences at Bath, Newcastle, and in London were quoted.

The following recommendations were formulated, with general concurrence: (1) that a separate way should be provided for each separate conductor, for the purpose of drawing in and out between flush boxes; (2) that the high-tension primary alternating currents should have concentric conductors with vulcanised rubber dielectric, and be drawn into iron ways; (3) that the arc lighting continuous current conductors should be concentric, and drawn into an iron way, except in the lengths where the circuit is connected with lamps, when the 7/16 conductors should be separate, so as to avoid joints.

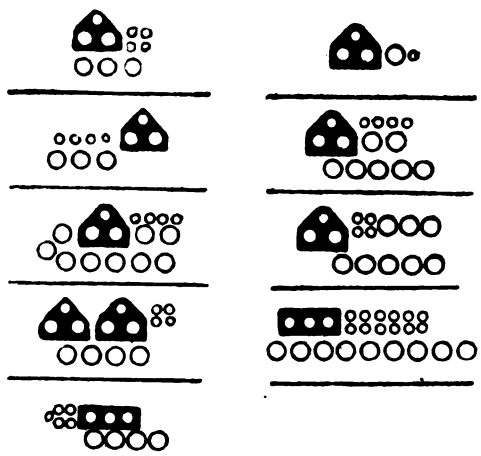

FIG. 10.—Various Typical Examples of Sections of Conduits.

In connection with the secondary distributing conductors, the use of the three-wire system having been admitted, various means of laying were examined—such as large iron pipes, with and without interior separate ways for the cable; the use of paper tubes in iron cases; iron tubes lined with bitumen: and earthenware cases, with ways similar to the Callender-Webber bitumen concrete cases. After carefully considering the conditions of the City streets, and all the circumstances of difficulty that were being met with and known to exist, the use of bitumen concrete cases with separate ways; and, in view of the experience and evidence of its efficiency, the use of Callender's bitumen insulation for the secondary distributors, met with approval. After hearing all that was to be said as to the conditions for providing drawing-in and joint boxes in the City streets, no doubt remained as to the necessity for using a common box in most situations for all main circuits and their joints, and of making them as large as the space below the surface would permit.

The justification of the adoption of these resolutions was, both from the engineering and financial point of view, as follows: The use of footways wherever possible had been prescribed by the Commissioners. In spite of having to keep 6in. under the lower side of the paving-stones, it entailed less labour in excavating. In the lines where they had to be carried under roadways, the conduits had to be below paving and concrete, sometimes 2ft. in thickness; with a surface subject to such traffic the numerous draw, service, and other flush boxes would have been impossible.

The following figures give an idea of the traffic in the City—by bridges, streets, railway stations, landing piers, and subways there are 81 means of public access. By these the daily traffic was:

	1881.		1891.
Vehicular—During 16 hours ...	66,909	.....	85,286
During 8 hours.....	4,984	.....	6,546
Pedestrian—During 16 hours...	739,640	.....	1,100,636
During 8 hours.....	57,923	.....	85,458

The space available below the surface was occasionally entirely occupied by cellars, areas, and other pipes, and the work had to be carried out in the presence of officials representing (1) the Commissioners of Sewers, (2) the Postmaster-General, (3) the gas-light company, (4) the water company, (5) the hydraulic main company, (6) the district surveyor. The condition, exacted rigorously—namely, that no pipe or conduit should be placed vertically over, or within 6in. horizontally of, an existing pipe—was a most arduous one to fulfil.

My procedure in the most difficult streets was as follows: Having decided on the maximum number of "ways" that should, and if possible be, laid under the footway, I began by examining it personally, having first obtained from the authorities I have named all possible information as to their pipes—information that was sometimes very imperfect. I then measured carefully all cellars, arches, and areas, and had trial holes opened wherever exceptional difficulty was anticipated. In many cases, such as in King William-street, so contracted was the space that several ways which were actually necessary had to be omitted and taken another way, and occasionally a deviation under the roadway was obligatory. The intricacies of the trench opened under such conditions could not, I believe, have been followed with any other system of ways—namely, the combination of Callender-Webber casing and wrought-iron tubes. Both these are capable of being bent on the ground to any reasonable curve—in the case of the iron pipes by the ordinary means, and in the case of the bitumen-concrete cases either by warming the case and bending it when soft, or by laying short lengths and setting them at an angle to one another with mitred ends; the length of the short pieces and the angle of the mitres being, of course, dependent on the radius of the segment of the curve that has to be followed.

The difficult problem that faced the company in August, 1891, was the obligation to lay down their mains and complete the public lighting in all parts of 53 streets by February, 1892, requiring approximately 17 miles of trench; and that the Commissioners were likely to be very stiff as to punctuality. A careful consideration of the case in its various aspects had led me, when acting (up to and before 1890) as technical adviser to the Brush Company, to regard the adoption of alternating currents, delivered at high pressure and distributed at low pressure, as the service most suitable for private lighting in the City. There was no hesitation on the part of all concerned to adopt it, particularly as in the case of the contractors the Mordey and Thomson-Houston systems had in in 1890 reached considerable perfection. The conditions which emphasised this view in my mind were geographical and local as regards the City. Whatever may have been the ultimate practice they were paramount during the preliminary stage. They were, first, on account of cost of ground, that the generating stations should be at a distance; second, on account of the exceptional difficulties in the streets for laying mains, the desirable frequency of converting stations might be impossible to achieve. When the *concessionaires—i.e.*, the contractors—had the matter in their own hands, the sites already named for the generating stations were secured in, or in close proximity to, the City. Although this was a reversal of conditions, the selections were probably wisely influenced by question of facilities for sea-borne coal and condensing water, and largely controlled by the difficulty created by the Electric Light Acts in getting way-leaves through the areas of neighbouring local authorities. For instance, negotiations extending over three years, with that object only, that I had conducted for the Brush Company with some local authorities on the Surrey side, ended only in obliging the company to seek and obtain a provisional order for the St. Saviour's district.

(To be continued.)

COMPANIES' MEETINGS.

CITY OF LONDON ELECTRIC LIGHTING COMPANY, LIMITED.

The ordinary general meeting of the above Company was held at Winchester House, Old Broad-street, yesterday (Thursday) afternoon, to receive the directors' report and accounts, which were given in our last issue. Sir David L. Salomons, Bart. (chairman of the Company), presided.

The **Chairman**, in moving the adoption of the report, stated that impartial people would agree that it gave a fair and impartial view of what had taken place. They did not regret the absence of fog during the winter, for it had enabled them to get their machinery erected. It was the pioneer station which had brought in the revenue, and they had increased from having 20,241 8-c.p. lamps on their system at the beginning of the past year, with a capacity of 34,000, to 65,341 8-c.p. lamps at the end of the year, with a capacity of 64,000. At the present time 76,000 lamps were connected, and the machinery had a capacity of 100,000. In addition, 25,000 lamps had been applied for, but they were not yet connected; they would be when the transformer stations were equipped. All the sub-stations should be ready by April, but allowing for delays they would in any case be completed by the end of the year. Taken on the basis of the present nine areas supplied, the other 13 areas should bring up the number of lamps to 180,000. The directors had started, apart from the ordinary reserve, a fund for the mains which was invested in consols. The total extinctions during two years' working only amounted to one hour. In order that the streets should not be placed in darkness by any accident, the arc lamps on different sides of the streets were fed from separate circuits. The City authorities had now ordered the gas-lamps to be removed from the thoroughfares lighted by the Company, and that showed that they had confidence in them. There would now be 23 miles of streets in the City lighted by electricity alone. They had received an order to light Smithfield Market, and hoped to receive one to light the lesser streets. The proposed issue of £100,000 in debenture stock at 5 per cent. would be revenue-earning. The directors were thinking of publishing quarterly returns like the railway companies. There were now 1,700 shareholders in the Company. Sir David Salomons, in conclusion, acknowledged the merits of the whole technical staff, who had worked most excellently.

Mr. Joseph B. Braithwaite, jun., seconded the adoption of the report, and pointed out that the cost of production of electricity had decreased by 32 per cent. as compared with the

Digitized by Google

preceding year. With regard to the issue of debenture stock, this had not taken them by surprise, for it had been anticipated in the original prospectus. The directors had pursued a steady and fixed policy from the beginning. The debentures would not only earn their own interest, but probably 15 to 20 cent. in addition.

The motion was then put to the meeting and carried.

The **Chairman**, in reply to Mr. W. Cooper, who drew attention to the returns of the Westminster Company with almost the same output and the same revenue, but which had a far smaller capital, pointed out that the Westminster Company was at its zenith, while they were engaged in initial work. In reply to other questions, he stated that the debentures would be issued in a few days at the price of £115, redeemable at £125 after the year 1911.

Sir David Salomons moved, and **Mr. Edward Lucas** seconded, the payment of a dividend at the rate of 6 per cent. on the preference shares, which was agreed to.

Mr. J. W. Reynolds moved, and **Colonel H. B. Martindale** seconded, the re-election of Sir David Salomons as chairman. This motion was adopted. Messrs. W. H. Pannell and Co. were re-appointed auditors, at a fee of 100 guineas, this terminating the proceedings.

WESTMINSTER ELECTRIC SUPPLY CORPORATION.

The ordinary general meeting was held at Eccleston-place, Westminster, on Wednesday, Lord Suffield in the chair.

The **Chairman**, in moving the adoption of the report, which was published in our last issue, congratulated the shareholders on the steady increase that had been going on in the business of the Corporation, and also in its income and dividends. He was glad to say that their revenue had largely increased, notwithstanding the adverse circumstances which had had to be encountered, and which included, first, the strong competition to which the Corporation had been exposed; in the second place, the fact that the charge per unit had been reduced by 1d. for nine months of the year; and thirdly, the abnormal amount of light that had prevailed during the winter to the almost entire absence of fogs. The aim of the Board had been to pay dividends out of actual profits, and to put the business of the Corporation on a sound basis rather than pay large dividends at the commencement. They were, however, highly pleased to be able to declare an increased dividend over the corresponding period of the previous year, after having written off several liberal amounts for preliminary expenses and patents, and making provision for depreciation, sinking fund, working expenses, and bad debts—the last-named item being small in amount. During the past year, in conjunction with other low-tension companies in London, the Board had come to terms with the Westinghouse Electric Company for the use of the Hopkinson patents for the three-wire system of distribution, and had obtained a license for the remaining term of the patents and any extension thereof. The cost of the license had been £3,878, and as the issue of the patents had saved a much larger expenditure in copper for the mains, the amount had been charged to capital. There was no likelihood of their having to incur any further outlay for patents of any kind. No item chargeable to revenue had been carried to the capital account, the plant, machinery, etc., being fully maintained out of the revenue of the year. The Corporation had been but little affected by the coal strike, as they had provided a large supply beforehand, which had carried them over the bad period. The installation of current to the mains for the supply of the Foreign Office had been satisfactorily accomplished. The Government authorities had decided on doing away with the plant previously supplied for lighting the Houses of Parliament, and would now take the whole supply for those buildings from the Corporation mains. It was hoped before long other large Government departments would be added.

Mr. J. H. Powell seconded the motion for the adoption of the report, which was agreed to unanimously.

On the motion of the **Chairman**, seconded by **Mr. Martin**, a dividend at the rate of 5 per cent. per annum was declared for the past half-year, and the chairman and Mr. Hayes Fisher, the retiring directors, having been re-elected, and the auditors, Messrs. Cooper Bros. and Co., having been reappointed, a vote of thanks to the chairman closed the proceedings.

ORIENTAL TELEPHONE AND ELECTRIC COMPANY.

An extraordinary general meeting of the Oriental Telephone and Electric Company, Limited, was held on Wednesday at the Cannon-street Hotel.

Mr. W. Addison, who presided, said that since the present Board had been directing the affairs of the Company, they had from time to time endeavoured to arrive at an understanding by which the two classes of shares into which the share capital was divided should be assimilated, thus abolishing the liability on the partly paid-up shares, and bringing in the vendors' shares for immediate dividend for reduced capital. A provisional agreement had now been arrived at, and though it was true that the ordinary shareholders would have to submit to a reduction of 1s. per share, it must be borne in mind that the vendors also reduced their 20s. shares by 4s. 6d. each. The paid-up capital would thus be reduced from £199,746 to £171,497. The ordinary shareholders would be relieved from all liability as to calls, and the holders of vendors' shares would come in for immediate dividend.

The **Solicitor** (Mr. J. Addison) having explained the proposal, resolutions were passed, after some discussion, providing for the voluntary winding-up and reconstruction of the Company for the purpose of carrying the scheme into effect.

CHELSEA ELECTRICITY SUPPLY COMPANY, LIMITED.

Directors: J. Irving Courtenay, Esq., chairman; Major-General Webber, C.B. (retired, R.E.) deputy-chairman; Nugent Daniell, Esq., Emile Garcke, Esq., Sir George Prescott, Bart. Managing engineer, Frank King, Esq. Secretary, S. J. Cluer.

Directors' Report.

The directors have pleasure in submitting to the shareholders the report and statement of accounts for the year ended December 31, 1893. The net profits of the year on the ordinary business of the Company, after payment of interest on debentures, amount to £4,004. 4s. 6d. This sum, together with the balance from the sale of the South Kensington district, gives a net balance of £6,605. 2s. 7d. To meet the wishes of the Board of Trade, the sum of £4,674. 3s. has been deducted from the item of "preliminary expenses" in capital account, and transferred to a suspense account, which account it has been decided to reduce by writing off £2,500. A further sum of £1,000 has been placed to renewals and depreciation fund account, leaving a balance of £3,105. 2s. 7d. available for distribution. The directors recommend the payment of a dividend on the ordinary shares of 5 per cent. for the year, and that the balance of £619. 4s. 3d. be carried forward to next account. In May last, the purchase of the works, machinery, and mains of the Cadogan Electric Light Company was concluded. The generating station, situated in Manor-street, Cheyne-walk, is of sufficient dimensions to contain plant to meet a large increase in the demand. Extensive improvements and additions are in progress at this station. During the year about 20,000 yards of new conductors have been laid. The increase in the number of lamps connected to the service during the year is 10,665; and, deducting the number of lamps transferred with the South Kensington district, the total number on the Company's mains on December 31, 1893, was 40,665. The transfer of the South Kensington district, authorised at the extraordinary general meetings held last year, was completed in June. The satisfactory reduction made in the last few years in the working cost is shown in the following statement of the cost per Board of Trade unit sold:

Year.	Coal.	Stores and water.	Wages.	Maintenance.	Rent, rates, and taxes.	Management.	Renewals and depreciation fund.	Total.	Capital expenditure.	Board of Trade units sold.
	d.	d.	d.	d.	d.	d.	d.	d.	£	
1891	2·22	·74	1·11	·93	·21	1·56	—	6·67	74,721	290,458
1892	1·63	·59	·95	·71	·21	1·26	·67	6·02	81,364	357,162
1893	1·11	·35	·80	·53	·48	1·17	·59	5·03	99,483	402,848

The retiring directors are Mr. J. Irving Courtenay and Mr. Nugent Daniell, who, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Bros. and Co., also offer themselves for re-election.

The annual ordinary general meeting of this Company was held on Tuesday at the central station, Draycott-place, Chelsea, Mr. J. Irving Courtenay, the chairman, presiding.

In moving the adoption of the report, the **Chairman** stated that the progress made during the past year had been so satisfactory that there was a considerable increase in the profits, the dividend of 5 per cent. recommended on the ordinary shares being double that paid last year on a paid-up capital over 10 per cent. larger than that of 1892. The dividend came out of the ordinary business of supplying current, and was independent of the exceptional item of £2,600, the balance from the sale of the rights of the South Kensington district. Considerable expenditure had been due to an extension in the mains, and a large area had been covered extending from the Chelsea-embankment on the south to the Fulham-road on the north. This area, it was expected, would develop in the future in the same way as the area previously occupied by the Company's mains. They had been fortunate in purchasing the works of the Cadogan Company at a time when an increase in their generating power was necessary. They were being arranged for 1,000 effective horse-power, which could supply power for 75,000 lamps of 8 c.p. fixed, or, say, 30,000 lamps in use at one time. The total number of lamps on the Company's mains at the end of the year was 40,665. The number of customers in the new area in which the mains had been laid was rapidly increasing, and there was also a large increase in the area previous supplied, and the Cheyne-walk station was about to be used to assist the Draycott-place station as well as to supply the new area. The condition of the plant was excellent, and its efficiency well maintained. The report showed that the cost of production had been reduced within the last three years by the amount of 1¾d. per Board of Trade unit sold, and there was last year a sale of 402,848 units. The number of units sold would have been larger still had it not been for the unusual absence of fog. The increase in capital expenditure had resulted in a much larger proportion of profits, as there were certain fixed charges which barely increased at all while the revenue increased, and adequate capital enabled the Company to provide and arrange their plant so as to give the best results. Fresh capital would have to be raised for the additional machinery and plant necessary to meet the growth of the Company's business. The directors consequently intended to exercise the powers already given them by the shareholders, and would at an early date make an issue of preference capital.

Major-General Webber, in seconding the adoption of the report, said that had there been seven more foggy days, with a consumption of six hours by three fourths of their lights, an extra 1 per cent. dividend could have been paid. This showed the possibility of future receipts, and current might also be bought in the daytime for motive power purposes.

In reply to Mr. J. King, **Major-General Webber** stated that part of the plant of the Cadogan station had been found useful, but it had been bought under the expectation of less than a moiety being of any service.

The motion was then put and adopted unanimously.

The retiring directors, Mr. J. Irving Courtenay and Mr. Nugent Daniell, were re-elected on the motion of Mr. Emile Garcke, seconded by Mr. J. King. Messrs. Cooper Bros. and Co. were reappointed auditors, their fee being increased from 25 guineas to 35 guineas.

In acknowledging a vote of thanks, the **Chairman** said that it had been a long pull to get the Company through, but he hoped they had now reached a secure position.

CHARING CROSS AND STRAND ELECTRICITY SUPPLY CORPORATION, LIMITED.

Directors: G. H. Brougham Glazier, Esq., 7, St. James's-street, S.W., chairman; Richard Chadwick, Esq., 34, St. Martin's-lane, W.C.; I. P. Mendoza, Esq., 4A, King-street, St. James's, S.W.; Agostino Gatti, Esq., and Stefano Gatti, Esq, 436, Strand, managing directors. General manager and secretary: E. Wilmot Seale, Esq. Chief engineer: W. H. Patchell, A.M.I.C.E, M.I.E.E.

Directors' Report.

The directors have to announce to the shareholders with very great regret the death of their chairman, the late Mr. Spencer Chadwick. Mr. George H. Brougham Glazier, the deputy chairman, has been chosen to fill the office of chairman, and Mr. Richard Chadwick (brother of the late Mr. Spencer Chadwick) has been elected a director until the ordinary general meeting. The Corporation was on December 31, 1893, supplying energy to 34,570 8-c.p. lamps, an increase of 17½ per cent. on the number supplied at the end of the year 1892. With the mains added during the past year, there are now upwards of 19½ miles laid. Two actions were brought against the Corporation for injunctions and damages, both of which resulted in judgments in favour of the Corporation on all points with costs The directors have given special attention to the question of maintenance, renewals, and repairs, and have expended a considerable sum in keeping the station in all respects in a very high state of efficiency; they have written £200 off preliminary expenses, made provision for bad debts, carried £700 to depreciation account, £200 to reserve fund, and carried forward £43. 0s. 1d. The net earnings during the past year amounted to £8,654. 8s. 4d; £2,685. 8s. 5d has been paid in respect of interest on debentures up to December 31, 1893, and £3,648. 7s. 11d. was distributed in payment of an interim dividend for the half-year ended June 30, 1893. A sum of £2,955. 10s. 1d. now remains, which the directors propose to deal with as follows: To payment of a dividend of 4½ per cent. for the

year 1893 (less tax)	£6,560	17	11
Interim dividend paid August, 1893	3,648	7	11
	2,912	10	0
Carried forward	43	0	1
	£2,955	10	1

Mr. Agostino Gatti and Mr. Stefano Gatti, the managing directors, are the directors who retire by rotation, and being eligible, offer themselves for re-election. Mr. Richard Chadwick being eligible also offers himself for re election as a director. The auditors, Messrs. O. R. Johnson and Son, also retire and offer themselves for re-election.

The annual ordinary general meeting of this Company was held at St. Martin's Town Hall on Tuesday, Mr. G. H. Brougham Glasier occupying the chair.

Before moving the adoption of the report, the **Chairman** expressed his regret at the death of the chairman of the Company, the late Mr. Spencer Chadwick. Continuing, he said that it was satisfactory to note that the Corporation had been successful in two actions brought against them for injunctions and damages. He then moved the adoption of the report, which recommended the payment of a dividend of 4½ per cent., less the interim dividend paid in August last.

Mr. J. P. Mendoza seconded the adoption of the report.

In reply to questions, the **Chairman** explained that the item of £6.041 against sundry debtors for current supplied to December 31, 1893, was due to the accounts being closed with the end of the year. A very large proportion of this amount had now been received. Asked as to why the dividend was only 4½ per cent., as against 5 per cent. in the preceding year, he attributed this mainly to the cutting of the rates by another company having rights in the parish. They had been obliged to lower the charges to be on an equal footing with them to secure customers, and it would have been useless to try and obtain higher rates than the other company. Had it not been for this cutting, a dividend of 6½ or possibly 7 per cent. might have been declared. He, however, believed that this competition in rates would not continue.

The motion was then put to the meeting and agreed to.

Mr. Agostino Gatti and Mr. Stefano Gatti, the managing directors, who retired by rotation, were re-elected, and Mr. Richard Chadwick was re-elected a director.

Messrs. O. R. Johnson and Son were reappointed auditors at a fee of 50 guineas.

DOVER ELECTRIC SUPPLY COMPANY.

The statutory meeting of this Company was held last week at the Company's Office, Castle-street, Dover, Sir William Crundall, J.P., chairman, presiding.

The **Chairman** stated that the meeting was held in compliance with the statute, and, to a certain extent, it was merely formal. The directors had gone to allotment, and a certain number of shares had been allotted; not so many as the directors would have wished, but there had been sufficient shares allotted to go on with the business. The directors would meet directly after this meeting, and would receive and decide tenders for the erection of the works. In conjunction with the works at once to be commenced, they would concurrently begin to lay mains along the roads, so that no time would be lost, and they hoped to begin to supply the current by August or September next. The directors proposed to hold in the course of a few weeks an electrical exhibition in the Town Hall. He thought that so far as Dover was concerned, there was a good prospect in view, as there is every probability of large customers.

A vote of thanks to the chairman terminated the proceedings.

Digitized by Google

GUERNSEY RAILWAY COMPANY, LIMITED.

The fifth annual general meeting of this Company was held last week at Hougue-à-la-Perre. A dividend of 2½ per cent. per annum was recommended by the directors to be paid upon the ordinary shares. This provoked some criticism as to the advisability of paying a dividend while the balance-sheet showed a total indebtedness of about £5,000, including debenture, preference, and loan interests due and unpaid to December 31. It was also pointed out that the total interest already to be paid annually, entirely irrespective of any return on the ordinary capital, was, according to the figures of the balance-sheet, about £700, but the motion was supported by several shareholders on the ground that the payment of a small dividend would act as an inducement to the shareholders to take up the remaining portion of the authorised capital. Subsequently the shareholders inspected the machinery and plant, and afterwards were conveyed to town by a special car.

COMPANIES' REPORTS.

SCARBOROUGH ELECTRIC SUPPLY COMPANY, LIMITED.

Directors: Lieutenant-Colonel R. F. Steble, chairman; G. Alderson-Smith, Esq.; John Dale, Esq.; John Woodall Woodall, Esq.; George Lord Beeforth, Esq.; John Bell Simpson, Esq.; the Hon. Charles A. Parsons; A. A. Campbell Swinton, Esq., managing director.

Report of the directors to be presented to the shareholders at the second ordinary meeting to be held at the offices of the Company on Thursday, March 1, at 11 a.m.

The directors have pleasure in reporting that the Company's electric supply station is now in full working order, that the business of the Company is steadily increasing, and that its prospects are most encouraging. On September 1 last, when the regular supply of electricity was commenced, there were connected to the Company's mains 468 8-c.p. lamps. By December 31 this number had increased to 4,114, and at the date of this report to 4,489. By the end of March it is anticipated that nearly 6,000 lamps will be connected. The present capacity of the generating plant provides for about 10,000 lamps, and it is therefore expected that the works will be fully employed before long. Seeing that it would have been inexpedient to commence a profit and loss account with only a small portion of the machinery at work, the directors have deemed it advisable to place all receipts up to December 31 to the credit of formation and preliminary management account. Mr. G. L. Beeforth, the Hon. C. A. Parsons, and Mr. G. Alderson-Smith retire by rotation, but are eligible and offer themselves for re-election as directors. The auditor, Mr. C. E. Bradley, C.A., also offers himself for re-election.

BALANCE-SHEET ON DEC. 31, 1893.

Electrical Engineering in Australia.—According to *Industries*, the city of Launceston, Tasmania, has accepted contracts for the lighting of the streets by electricity, and the work is expected to be completed by the end of June. Seven tenders in all were received, ranging from that of Messrs. W. T. Glover and Co., of London, for £10,119, to the tender of the Electric Construction Company, Wolverhampton, for £38,335. The city surveyor has also been instructed to submit his views as to the best route for a tramcar service for the city.

BUSINESS NOTES.

Aberdeen.—It appears that the pillars in Union-street for electric lighting cost £4. 10s. each.

Personal.—The address of Mr. E. C. B. Tudor, engineer and surveyor, is now West House, Goole.

Western and Brazilian Telegraph Company.—The receipts for the week ended February 16 were £3,287.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 18th inst. amounted to £671.

Yarmouth.—The Town Council have accepted the tender of Mr. J. F. W. Bray to construct an electric lighting station for £2,620.

West India and Panama Telegraph Company.—The receipts of this Company for the half-month ended February 15 were £2,615, as against £3,009.

Fleetwood.—At a meeting of the Improvement Commissioners the clerk mentioned that certain slight alterations made would enable the Brush Company to complete the plans straight away.

Lighting of Engineering Works.—The engineering works recently acquired by Messrs. Baird, Thompson, and Co., almost opposite to the Agricultural Hall, Islington, N., are to be lighted by electricity.

Tenders for Ballymena (Ireland).—As mentioned in our last issue, tenders are invited by the 3rd proximo for lighting the town, either by gas or electricity, from August 16, 1894, until May 16, 1895, for the Town Council.

Ayr.—The Town Council have had outlined two schemes for lighting the town by electricity, the initial cost being between £16,000 and £18,000. The Council have agreed to get a further report regarding the matter.

Telephony.—The police stations at Cowbridge, St. Nicholas, Penarth, and Barry Dock have just been connected by means of telephonic communication, St. Nicholas serving as a kind of private exchange between the different places named.

City and South London Railway.—The receipts of the Company for the week ending February 18 were £938, against £938 for the same period last year. The total receipts for the first half-year of 1894 show a decrease of £135 compared with those for the corresponding period of 1893.

The Islington Tenders.—As stated fully in our last issue, the Vestry of St. Mary, Islington, invite tenders by March 21 for supplying and erecting the necessary plant and machinery for the supply of electricity in the parish, and for supplying the conduits and mains, which will be laid by the Vestry.

Withdrawal from Partnership.—Messrs. Wm. Peto and Radford inform us that they have purchased from Mr. Charles H. Cathcart his entire share and rights in the firm of Messrs. Cathcart, Peto, and Radford, and that they intend to carry on the firm as before, under the title of Messrs. Peto and Radford.

Lavatory Ventilation.—The two large underground lavatories at the London and Westminster Bank head office are now ventilated by means of an electrically-driven fan, run off the generating plant used for lighting the bank. This ventilating work was carried out by Messrs. Allpress and Co., of 55, Victoria-street, Westminster.

Halifax.—It is suggested that the Corporation, which is about to erect a central electric lighting station, should make a trial of the Livet process of generating power by the combustion of rubbish, and to which reference was made in our last issue. It is said to be understood that the Electric Lighting Committee will put down one of the Livet furnaces as an experiment.

Office-Lighting at Burnley.—The clerk to the Board of Guardians mentioned at a meeting last week that the Finance Committee had met that morning, and resolved to recommend the Board to light certain of the rooms in that building with the electric light, and to accept a tender at an estimated cost of £45. The proposition that Mr. Fletcher's tender be accepted was carried.

Tenders Wanted for Bury.—As stated in our advertisement columns, the Technical School Committee of the Corporation of Bury invite tenders for the supply of electric light fittings, including switchboards, lamps, wiring, etc., for lighting the technical school now in course of construction in Broad-street, Bury. Tenders to be delivered to the borough engineer by March 10.

Newcastle.—The Board of Guardians have agreed that the Workhouse Committee should obtain the opinion of an expert as to the probable cost of illuminating the workhouse by electricity. The electric lighting of Eldon-buildings (whichare now being erected on an important site in Newcastle-on-Tyne) is being carried out by Messrs. Allpress and Co., of 55, Victoria-street, Westminster.

Electric Tramway at Reading.—The tramways company contemplate applying to the Corporation of Reading for permission to lay down an electric tramway shortly. The company hope to adopt the overhead system, which Mr. J. Clifton Robinson, C.E., the manager of the Southern Tramways Company, a gentleman also interested in the Reading tramway, has persuaded the Bristol Company to introduce.

Adjustable or "Perfect" Pendant.—Reports having been spread that the patent term of this well-known fitting had expired, Messrs. Faraday and Son, of 3, Berners-street, W., think it worth while to make known that the renewal conditions have been periodically complied with. They hold exclusive rights

Digitized by Google

from the patentee to manufacture, and many years must elapse before the patent becomes void.

Morecambe Electric Light and Power Company.—The revenue account from November 16, 1892, to December 31, 1893, shows an expenditure of £1,361, and revenue £1,546, leaving a gross profit of £189, reduced by £92 for interest on borrowed capital and bad debts (£9), leaving a balance of £88, which the directors recommend to be applied to the payment of a dividend of 2 per cent. per annum on the paid-up share capital.

Wiring Tenders Required — Tenders are required for the electric light wiring of the town hall in course of erection at Morley (Yorks.). Specifications, plans, and particulars may be obtained from Messrs. Holtom and Fox, architects, Dewsbury, on deposit of £1, which will be returned on receipt of a *bonâ fide* tender. Sealed tenders, endorsed "Wiring," to be sent in to Mr. R. Borrough Hopkins, town clerk, Morley, by 26th inst.

Keighley.—At a meeting of the Town Council this week Mr. Foulds asked, in regard to the proposal to apply for powers to provide the electric light, whether it had been definitely settled to make an installation, and suggested that a separate committee should be constituted to deal with the subject. It was explained that the present steps were only provisional, and that due notice would have to be given before powers were applied for.

The Brush Company's Dividend.—The directors of the Brush Electrical Engineering Company, Limited, have declared an interim dividend at the rate of 6 per cent. per annum on the preference shares, and at the rate of 5 per cent. (the maximum which, according to the articles of association, can be paid on an interim dividend) on the ordinary shares of the Company for the six months ended December 31, 1893, payable March 1, 1894.

Penistone.—At a meeting of the Local Board the clerk read a letter from the Electrical Engineering Company, Limited. The letter pointed out that they had carefully examined the map and general conditions furnished by the Board, and had come to the conclusion that it was not practicable to submit a scheme of lighting by electricity a total of less than 200 lamps of 16 c.p., distributed over 4¼ miles of road, which would be a commercial success.

Edinburgh.—The Cleaning and Lighting Committee of the Town Council made recommendations on Tuesday on the subject of electric lighting: (1) that if four of the 160 lamps already authorised for the first installation in the city were available, the Lawnmarket should be lighted by electricity; (2) that no action should be taken in the meantime as to the lighting of George-street and St. Andrew-square and the cross streets from Princes-street with electricity. The recommendations were approved.

Tenders for Harrogate.—As well be seen from our advertisement columns, the Corporation of Harrogate invite tenders for the following plant in connection with the proposed electricity works: refuse sorting and drying plant, with accessories, steam-boilers and accessories, steam and exhaust pipes, transformers and accessories, distribution mains. Specifications for all or any section may be obtained on application to Mr. Samuel Stead, borough surveyor, Municipal Offices, Harrogate, on payment of £1. 1s. Tenders must be sent in by March 14.

A Cornish Boiler Required.—Tenders are invited by the 26th inst. for the supply of a Cornish boiler for the electric light station, Abercorn Basin, for the Belfast Harbour Commissioners. Copies of specification, forms of tender, and any further information required may be obtained from the harbour engineer, Mr. G. F. L. Giles. Sealed tenders, on the special forms provided for the purpose (accompanied by drawings), to be addressed to Mr. A. W. Currie, secretary, Harbour Office, Belfast, endorsed "Tender for Boiler," and sent in by 26th inst.

Ince.—The second meeting of the Gas Enquiry Committee of the Local Board was held on the 26th ult. Some discussion took place as to the adoption of the electric light for street and general lighting. It was agreed to make enquiries at places where electricity is employed as to the cost and advantages of the system, and for this purpose representatives are to be appointed to visit the districts where information on the matter can be obtained. It was decided to hold a meeting on March 2 to receive the reports of the deputation.

Sheffield.—The Improvement Committee of Sheffield City Council on Monday passed the following resolution: "That provision be made for a supply of electricity throughout the new Town Hall, and for a modified supply of gas to light the corridors and staircases; that the architect be requested to report to what extent this modification of gas supply will reduce the contract; and also to report whether, in his opinion, it would be desirable to dispense with gas altogether, and in that case what further reduction would be effected."

Insulated Cables Required.—Tenders are invited by the 26th inst. for providing and fixing, in lieu of existing wires, insulated cables for electric lighting purposes, on portions of their property, for the Swansea Harbour Trustees. Particulars, information, and forms of tender may be obtained on application to the Trustees' engineer, Mr. A. J. Schenk. Tenders, addressed to Mr. Talfourd Strick, clerk, Harbour Offices, Swansea, and marked on the outside "Tender—Electric Lighting," should be delivered at the Harbour Offices, Swansea, by the date mentioned.

Tenders for St. Pancras.—The St. Pancras Vestry invite, as stated in our advertisement columns, tenders for the following works: (1) Lancashire boilers, economiser, feed pumps, etc.; (2) engines, dynamos, condensing plant, etc. The drawings can be inspected, and copies of the specifications, bills of quantities, and general conditions can be obtained at the offices of Prof. Henry Robinson, C.E., 13, Victoria-street, Westminster, on payment of 10s. for each. Tenders are to be sent in to Mr. Albert E. Pycraft, chief clerk, Electricity and Public Lighting Department, Vestry Hall, Pancras-road, N., by March 5.

Wakefield.—The committee having in hand the question of electric lighting met on the 22nd ult. The town clerk read letters from Messrs. Harrison, Beaumont, and Smith, acting on behalf of the Wakefield Union Rural Sanitary Authority, requesting to have a clause inserted in the electric lighting provisional order to the effect that without the consent in writing of that Authority, the Corporation should not, either directly or indirectly, supply energy or power within the Authority's district, and forwarding draft of clause as proposed by them. The committee resolved to object to the insertion of such clause in the order, and the town clerk has been instructed to oppose its insertion.

Tenders Required for Edinburgh.—The Corporation of Edinburgh invite tenders, as stated in our advertisement columns, for the following work in connection with the electric lighting of the city: Contract No. 5, construction of concrete culverts and laying of stoneware and iron pipes and casings; No. 6, supply of cast-iron pipes, casings, and road service boxes; No. 7, supply of stoneware casings and insulators; No. 8, supply of copper strip; No. 9, supply of armoured and unarmoured insulated cable. All information will be supplied by Prof. Alex. B. W. Kennedy, the consulting electrical engineer to the Corporation, at his office, 14, Old Queen-street, Westminster, London, S.W.

Telegraph Construction and Maintenance Company.—The report for 1893 states that the accounts show a net profit of £99,435, after charging the interest on the debentures. To this is added £41,433 brought forward from 1892, making a total of £140,868. From this sum is deducted the interim dividend of 5 per cent., paid in July, amounting to £22,410, leaving £118,458 to be dealt with. It is proposed to distribute a dividend of £1. 16s. per share, absorbing £67,230, being at the rate of 15s. per cent., and making, with the amount already paid, a total dividend for the year of £2. 8s. per share, or 20 per cent., free of income tax, leaving £51,228 to be carried forward to the next account.

Hanley.—The Electric Lighting Sub-Committee of the Town Council have recommended that various tenders, amounting to £207. 10s., be accepted for instruments and tools, and other tenders, amounting to £1,000, for meters, switches, cables, fuses, and general stores; also the tenders of Messrs. Spagnoletti and Crookes for the electric wiring and fittings required in the Corporation buildings, amounting to £3,034. 14s. 1d. This sum is divided as follows: Town Hall and Victoria Hall, £1,408; free library and boys' reading-room, £129; museum and technical schools, £155; public baths, £144; market hall and fish market, £878; butchers' market, £176; the electricity works, £110. The recommendations have been adopted.

Electro-Chemical Company, Limited.—This Company has been registered with a capital of £200,000, divided into 26,000 £10 per cent. preference and 14,000 ordinary shares of £5 each. The object is to acquire from the Electrolytic Caustic Soda and Chlorine Trust Limited, British patent No. 2,296 of 1890, for improvements in the electrolytic production of caustic soda, caustic potash, and other products from their salts, and other patents for inventions relating to electrolytic and electro-chemical operations and apparatus therefor; to manufacture, prepare, sell, and deal in caustic soda, caustic potash, sulphuric and hydrochloric acids, etc. The first signatories are Messrs. Lewis Evans, Leopold Field, Thos. M. Dunster, Wm. S. Wakefield, Wm. G. Taylor, Thos. Hitchcock, Randal Vogan.

Tynemouth.—On Wednesday the Trade and Commerce Committee of the Town Council reported that the borough surveyor had submitted to them a report of a sub-committee in reference to electric lighting in the borough. The sub-committee's report stated that Messrs. C. A. Parsons and Co. only had tendered for the carrying out of such works as were necessary to retain the powers conferred by the provisional order; that the tender for laying electric mains in Saville and Howard streets amounted to £1,355; for a dynamo which will energise 700 10-c.p. lamps, £445; and for lighting the Town Hall Buildings, £162; making a total of £1,962. The sub-committee recommended that application be made to the Local Government Board for sanction to borrow £2,000 to carry out the scheme, but that only £1,355 for electric cables be expended at present. The report was adopted.

Presentations.—Mr. Cutler, assistant engineer at the Bath Electric Light Works, has been presented with a handsome barometer by Mr. F. Hallows, on behalf of the staff, on the occasion of his resignation as assistant engineer. On Saturday a large company assembled at the Park Hotel, De Grey-street, Newcastle, the occasion being a presentation to Mr. Jos. Askew, who has been employed as a foreman in the Elswick Ordnance Works for upwards of 15 years, and who is leaving to fulfil an important situation in the electrical engineering works of the Fowler Waring Cables Company, North Woolwich. The presentation, which consisted of a handsome gold watch, was made by Mr. Curry. Mr. Arthur Watts, local manager of the National Telephone Company's Newcastle district, was the recipient the other evening of a handsome silver tea and coffee service, presented by the local staff.

Lighting of Newspaper Offices.—The offices of the *Morning* newspaper are to be lighted by electricity, and Messrs. Drake and Gorham have been commissioned to carry out the work. The plant will consist of a Crossley "Otto" high-speed gas-engine of 14 brake horse-power, fitted with patent tube ignition and the latest improvements. The generator will be an Electric Construction Company dynamo wound for 90 amperes at

Digitized by Google

105 volts for direct running. Spring contact main switches, the patents for which are held by the firm, will be adopted. The lights at present to be arranged for are 140, but this number will probably be increased later on to 200. A special bracket for outside use has been designed by the firm for carrying an arc lamp containing a device of the *Morning*. In addition to the electric light installation, a complete system of electric bells is being fitted.

Ossett.—On Monday a meeting was held at the Ossett Technical School, convened by resolution of the Ossett Tradesmen's Association, to take into consideration the price and quality of the gas supplied to Ossett and Horbury by the Ossett Gas Company. Mr. Frankland mentioned that, as the electric light was the light of the future, the town ought not to be saddled with the gas plant. The ex-Mayor (Mr. F. L. Fothergill) stated that, in consequence of the quality and price of the gas, he had recently followed the example of two other millowners in the borough by putting down an electric lighting plant. The Ossett Co-operative Society would, he believed, shortly do the same thing unless some alteration was made. An application was also intended to be made for a provisional order authorising the supply of electricity for lighting purposes in Ossett, and that application would go forward unless the Corporation made a similar one.

Llandudno.—The engineer to the Improvement Commissioners reported on Wednesday that he and the gas manager had looked into the question of supplying an additional six millions of gas per annum to the proposed electric light company, and he estimated that in case the electric light would be well received it would make a difference in the output of gas to the extent of one and a half millions. The Gas Committee recommended that the Board sanction the scheme for the proposed electric lighting, and consent to the application by the company for a provisional order, satisfactory terms being first agreed upon with respect to the sale to the Commissioners with a specified time of the undertaking, the committee to at once enter into negotiations with the promoters. On the motion of Mr. Elias Jones, the electric light and water-supply questions were referred to a committee of the whole Board and the promoters of the company.

Lighting in the City.—At a meeting on Tuesday of the Commissioners of Sewers, Mr. Burmester, the chairman of the Streets Committee, presented a report on the subject of an application by Mr. Bibra, of the Champion Hotel, 15, Aldersgate street, to erect two standard electric lamps on the kerb in front of his premises, and recommended that the application should not be complied with. Mr. Deputy Dowling moved as an amendment that the application should be complied with. Mr. Deputy White, in seconding the amendment, said he thought some consideration should be given to the fact that the applicant had spent between £3,000 and £4,000 on improvements at the Champion Hotel. Eventually, the application was referred back to the committee At the same meeting, Mr. King enquired whether anything had been done on the question as to the appointment of an electric light inspector. In reply, Mr. Burmester stated that the matter had been referred by the committee to Mr. W. H. Preece, and a report on the subject would be shortly presented to the Court.

Lighting in Jersey.—At a States meeting an Act of the committee for the lighting of the town of St. Helier with respect to the illumination of the town was read. There had been communication from the Aurora Electric Lighting Company, which offered to supply light at certain fixed charges, but the committee had come to no conclusion on the matter. The Constable of St. Helier thought they should also discuss at the same time a petition concerning electric lighting in Jersey from Messrs. Allbright, Grand, Binet, Howell, and Hoyle, of London; also a bill thereon, and correspondence as to the protection of telegraph wires, etc. He thought it would be better to refer all three documents, which really formed one subject, to a committee which would seriously consider the same. The Deputy of St. Saviour pointed out that these certain petitioners asked for a 42 years' concession and the right to sell the same. The Rector of Grouville said the Asylum Committee was thinking of lighting the institution by electricity. Why not refer the subject to them? The matters were referred ultimately to a special committee.

Birmingham Market Hall.—On Tuesday, at a meeting of the City Council, Mr. Parkes moved that the scheme (to which reference was made in our issue of the 9th inst.) for lighting the Market Hall by electricity be adopted, and that the Finance Committee be instructed to borrow £1,000 for providing the necessary lamps, fittings, etc. He explained that for some time past the lighting of the market had been very unsatisfactory. He had to make what, he said, might be regarded as a startling statement—namely, that the electricity would come out cheaper than gas. The first reason for this was because of the wasteful character of the gas lighting of the Market Hall, and the second because they had special terms from the electrical supply company. For the £525, which was the estimated cost of the electric light, they would light the outside as well as the inside of the market. Inside there would be 32 lamps, and outside eight lamps—two at the Bull Ring end, two at the Worcester-street end, two in Philip-street, and two in Bell-street. It had been said that the tenants did not desire the electric light, but that was a mistake. The tenants would pay for it as they had paid for the gas. The committee were perfectly prepared to stand by the figures they had given. The motion having been seconded, was adopted after some discussion.

Lighting at Taunton.—It was reported at a meeting of the Town Council last week that the cables had been laid, as arranged with Dr. Fleming, from the No. 1 sub-centre, which is formed under the town clerk's office, and tested to 4,000 volts, and that the transformer would shortly be fixed and at work. The electrical engineer reported that, with the assistance of the borough surveyor, they had laid the low-tension network and feeders, and were laying the high-tension cable for the first sub-station They had received the Davey-Paxman "Economic" boiler. Since December 17 one-half of the public arc lamps had been alight until 6.30 a.m. They had fixed meters on all the larger consumers' mains, and were awaiting Dr. Fleming's report on the small meters to obtain and fix them. The Electric Lighting Committee stated that a letter had been received from Messrs. Newton, offering to make a 30 kilowatt transformer, and to let the Council have it on loan; also to make and send a second transformer to the same specification to Dr. Fleming to test, on the understanding that if they proved satisfactory the Council would purchase both of them as soon as it is decided to start another sub-station, at the price of £183 each. The committee recommended that their offer be accepted. The committee asked the Council to empower them to accept Messrs. Babcock and Wilcox's estimate for cross drains and the steam-piping necessary to connect them with the engines and boilers at the electric lighting station, at the price of £170, subject to the approval of Dr. Fleming. These reports were adopted.

Lighting at Maidstone.—The Electric Lighting Committee of the Local Board reported last week that they had considered the schemes and proposals submitted to the Board by various companies and private individuals for taking over the Maidstone electric lighting order, and that they were of opinion that those of Messrs. Bourne and Grant were the most advantageous. The committee therefore recommended that further negotiations be entered into with that firm with a view to coming to satisfactory terms and arranging for a transfer of the order. Alderman Ellis (chairman of the committee) said that this question had been before the Board from time to time, and now, after inviting proposals from various firms for taking over the electric lighting order, the committee had come to the conclusion that that of Messrs. Bourne and Grant was the most favourable. The offer of Messrs. Bourne and Grant was to supply, not only the streets set down in the order, but a number of other streets. The Authority were to be at liberty to purchase at the end of 21 years, or at the end of another five years, up to the forty-first year, on paying the fair market value as a going concern, and excluding any consideration for future profits, such market value to be obtained by arbitration. Alderman Long thought they ought to have a little more time to consider the matter before voting upon it. He only received a copy of the report the previous night. Mr. Barker supported the adoption of the report, because as a member of the Lighting Committee he felt it was the best thing they could do. Eventually the matter was postponed for a fortnight.

Electric Lighting at Cardiff.—A meeting of the Electric Lighting Committee of the Cardiff Corporation was held on Tuesday, Councillor Vaughan presiding. Alderman Jacobs said that now Mr. Massey, the consulting electrical engineer, was present, he would draw attention to an article which appeared in a local paper suggesting the utilisation of a destructor for the purpose of generating electricity in connection with the lighting of the town. The matter was mentioned to Mr. Massey when they visited the various towns some years ago, and at that time he (Mr. Massey) thought that it would not apply under the circumstances then. They had learned that at Halifax the idea had been a great success. They had been thinking of erecting a refuse destructor in Cardiff, and he thought it would be worth while considering whether they could use the destructor for lighting purposes. Mr. Massey reminded the committee that the use of a destructor had been thought of in all the reports presented to the committee. With regard to the destructor at Halifax, after carefully reading that article in the local paper, and speaking seriously of the schemes, he thought it an attempt to impose upon the British public. Mr. Harpur, the borough engineer, said that in those matters they were continually putting the cart before the horse. It did not follow that because they were erecting electric lighting works that they must erect a destructor as well. Mr. Massey wished it to be understood that his remarks with regard to the imposition on the public referred to Halifax. He intimated that so far 10,329 yards of pipework had been executed. A new system had been created, which would prevent such accidents as occurred at Bournemouth some time ago. The work in connection with the electric lighting is progressing. Three boilers are in place, brick seatings finished, engine and dynamo foundations completed, and floor laid. The travelling crane has been up now for some time, and the condensing apparatus is delivered and ready for erection.

Elmore Guaranteed Dividends.—In the City of London Court, on Monday, before Mr. Commissioner Kerr, the case of McGeagh *v.* Elmore's Foreign and Colonial Patent Copper Depositing Company, Limited, came on for hearing. Mr. H. C. Richards appeared for the plaintiff; the defendant company was unrepresented by counsel. Mr. Richards said his client was induced to take shares in Elmore's French Patent Copper Depositing Company by seeing a statement in the prospectus that a dividend of 10 per cent. would be guaranteed for the first year by Elmore's Foreign and Colonial Patent Copper Depositing Company, and that there would also be a participation in further profits. The amount guaranteed had not been paid. The secretary to the French company (Mr. J. Shurmur) was also secretary to the guaranteeing company, and the defence set up was that the prospectus making the statement was issued without the authority of the guaranteeing company. Mr. Shurmur was then put into the box. Mr. Richards: You were secretary to the guaranteeing company when the prospectus was issued?—Yes. Was that prospectus true when you put your name to it as secre-

Digitized by Google

tary?—I believe so. Was that paragraph true that the 10 per cent. had been guaranteed by the Elmore's Foreign and Colonial Company? Quite true. You have paid the guaranteed dividend to a good many of the shareholders?—The French company has. Where has it got the money from?—From the guaranteeing company. Why have you declined to pay Mr. Forster McGeagh?—His shares were of an issue upon which the dividend had not matured at the time we paid those dividends that did mature. In reply to Mr. Commissioner Kerr, witness said the prospectus was not issued actually by the foreign company; they were not responsible for the actual working of it. The Elmores had guaranteed the dividend under certain conditions. Plaintiff's claim, he thought, was amply satisfied by the scheme of resuscitation. Mr. Richards said the case was a test case, and other shareholders were awaiting the result of it before themselves taking action. Mr. Commissioner Kerr (to witness): You must bring the money into the court. Mr. Shurmur: Every other contributory has come into the scheme; they have not been paid their dividends. The case was adjourned for a week.

PROVISIONAL PATENTS, 1894.

FEBRUARY 12.

2990. **Improvements in electric tramways.** Thomas Parker, Tettenhall, Wolverhampton.

3013. **Improvements in apparatus for drawing through electrical or other cables or conductors in underground pipes or conduits.** S. A. Mahood, 4, Bagnall-street, Hanley, Staffordshire.

3020. **Improvements in induction electrical machines.** Frederick Tudsbury, 15, St. James's-row, Sheffield. (Complete specification.)

FEBRUARY 13.

3052. **Improved method of advertising by means of an electric lamp.** John William Ewart, 23, Ampthill-square, London.

3056. **Improvements in and relating to electrical safety fuses.** Alexander Marr, 70, Market-street, Manchester.

3072. **Improvement in arc lamps.** John Edward Woolverton, 154, St. Vincent-street, Glasgow. (Complete specification.)

3079. **An electric bell indicator.** Henry Sanders, 272, Summer-lane, Birmingham.

3080. **Improved method of fixing electric call-bells.** William Paul Theermann, Walter Crookell, and George Christopher Elliott, 2, Great Ducie-street, Manchester.

3101. **Improvements in armatures for dynamo-electric machines.** William Brooks Sayers, Henry Alexander Mavor, William Arthur Coulson, and Samuel Mavor, 46, Lincoln's-inn-fields, London.

3108. **Electric railways.** Paul William Leffler and Charles Eugene Corrigan, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

3109. **An electric locomotive for combined adhesion and rack traction.** John Imray, 28, Southampton-buildings, Chancery-lane, London. (Francis Rinecker, Germany.)

3111. **Improvements in electric signalling devices.** Reginald Haddan, 18, Buckingham-street, Strand, London. (Alexander Scott Williams, United States.) (Complete specification.)

3118. **Improvements in the regulation of electric motors.** Illius Augustus Timmis and Alfred Ivor Smith, 2, Great George-street, Westminster.

3125. **Improvements in armature connections for dynamos.** Oza Dufault, 53, Chancery-lane, London.

FEBRUARY 14.

3155. **Combined casings and insulators for electric wires.** William Williams and Thomas Bertram Johnston, 2, John-street, Bristol.

3166. **Improvements in underground conductors of electrical tramways.** John Brierley Howard, Penny Bank-chambers, Halifax. (Wilhelm Simon, Wolfgang Beissbarth, and Julius Beissbarth, Germany.)

3217. **Improvements in electric arc lamps.** Henry Francis Joel, 44, Lavender-grove, Dalston, London.

3223. **Improvements in heating of gases by electricity.** William Donaldson, 1, Queen Victoria-street, London. (Complete specification.)

FEBRUARY 15.

3245. **Improvements in lead-covered electric cables.** David Cook, 30, Lancaster-park, Richmond, Surrey.

3273. **Improvements connected with arc lamps.** Arthur Chester and John James Rathbone, 166, Fleet-street, London. (Complete specification.)

3277. **Improvements in the construction and methods of manufacture of electrical cables.** George Hinde Nisbett, 248, Stanstead-road, Forest Hill, London.

3291. **Improvements in electric arc lamps.** Alfred William Money and Herbert Nash, 23, Southampton-buildings, Chancery-lane, London.

3294. **Improvements in electric lighting apparatus for gas burners.** Mortimer Peterson, 46, Lincoln's-inn-fields, London.

3312. **Improvements in electric arc lamps.** Henry Hayes Cooper and the Electrical Installation Company, Limited, 53, Chancery-lane, London.

FEBRUARY 16.

3363. **Improvements in arc lamps.** Samuel Sealy Allin and William Henry Wood, 52, Woodstock-road, Bedford-park, London.

3376. **Improvements in appliances or means for securing the covers to the casings of electric light wires, applicable also to other purposes.** John Bailey Holroyde, 6, Bank-street, Manchester. (Charles James Holroyde, Australia.)

3384. **Improvements in incandescent electric lamps.** Joseph Walter Turnbull, 77, Chancery-lane, London. (Complete specification.)

FEBRUARY 17.

3422. **Improved method of and means for generating steam by electricity.** William Rockcliffe, 3, St. Nicholas-buildings, Newcastle-on-Tyne.

3426. **Improvements in electric lamps and in the holders or sockets therefor.** David Hunter and William Alexander Jack, 70, Wellington-street, Glasgow.

3450. **An improved flexible and electrically insulating shaft coupling.** William Richard Wynne, 5, New-court, London. (Complete specification.)

3468. **Hygienic safety device or guard for telephones.** Emil Pollak, 28, Southampton-buildings, Chancery-lane, London.

3469. **Improvements in dynamo-electric and electro-dynamic machines.** Paul Pöschmann and Richard Hanisch, 191, Fleet-street, London.

3476. **Improvements in and connected with electric bells.** Howard Blain Little, 115, Cannon-street, London.

SPECIFICATIONS PUBLISHED.

1886.

1999. **Electric lamps.** Swan. (Second edition.)

1889.

10640. **Arc lamps.** Crampton and another. (Second edition.)

1891.

19704. **Application of depolarisers in electrolysis.** Richardson. (Second edition.)

1892.

18039. **Electrolytic cells, etc.** Hargreaves and Bird. (Second edition.)

19194. **Telephones.** Langdon-Davies.

21480. **Measuring electricity.** Anders and Kottgen.

1893.

2267. **Electrolytical separation of bases of salts, etc., from saline solutions.** Vautin.

NOTES.

Prof. Tyndall's Will.—The value has been sworn at £21,866 of the personal estate of Prof. John Tyndall, who died on December 4 last.

Private Bill Legislation.—The Bills dealing with the Central London, and Charing Cross, Euston, and Hampstead Electric Railways will first come before the Commons.

Liverpool.—The Liverpool Electric Supply Company had connected to the mains on December 31 last 25,784 16-c.p. lamps, as against 20,254 lamps at the end of the previous year.

"Street Railway Journal."—The offices of the *Street Railway Journal* have been removed from the World Building to the Havemeyer Building, 26, Cortlandt-street, New York City.

Lighting of Omnibuses.—A new competitor in the field of lighting omnibuses by electricity has just made his appearance in the Metropolis, and to which reference is made in another column.

Croydon.—The Croydon County Council on Monday referred back to committee a motion that application be made to the Local Government Board for sanction to borrow £25,000 for electric lighting purposes.

Students of the Institution.—A students' meeting of the Institution of Electrical Engineers will be held this (Friday) evening at 28, Victoria-street, Westminster. Mr. E. H. Bowyer will read a paper on "Lightning."

The Institution.—The note by Mr. Mordey on "Parallel Working through Long Lines," the reading of which was postponed on the 22nd ult., will be presented at a meeting of the Institution on Thursday next, the 8th inst.

Communication between Passengers and Train Staff.—The Great Indian Peninsula Railway authorities have recently tried on local trains an electrical system designed for this purpose by their late telegraph superintendent, Mr. A. R. Simkins.

Book Received.—A copy of "The Engineer's Year-Book of Formulæ, Rules, Tables, Data, and Memoranda in Civil, Mechanical, Electrical, Marine, and Mine Engineering," by Mr. H. R. Kempe, A.M.I.C.E., M.I.E.E., has reached us from Messrs. Crosby Lockwood and Son."

Electrical Specialities.—A list of electrical specialities has been issued by Messrs. Miller and Woods, of 2, Gray's-inn-road, W.C. The list deals with transformers for heating medical cauteries, sub-divided transformers, lamp water (coffee) heaters, medical battery boxes, etc.

Crystal Palace Order.—With regard to the Crystal Palace and district electric lighting provisional order, which is practically in substitution for the license recently granted to the company extending its area of supply, the London County Council have decided to take no action in the matter.

Lighting Cold-Air Stores.—The extensive cold-air stores now being erected in Water-street for the Manchester Corporation at a cost of £100,000, are to be lighted by electricity produced by generators laid down on the premises. In addition to this, electric motors will be used for driving fans for circulating air throughout the buildings.

The Junior Engineering Society.—The fifth ordinary meeting will take place on Friday evening, the 9th inst., at the Westminster Palace Hotel, Victoria-street, S.W. The paper to be read and discussed is on "The Design, Construction, and Working of Boilers for Locomotive Engines," by Mr. G. Frank Burtt, G.I.Mech.E., member.

Traction at Bristol.—The Bristol Town Council on Tuesday sanctioned a proposed tram extension, which the Bristol Tramways and Carriage Company are undertaking at a cost of £50,000. The new branch will extend 3½ miles to St. George, which has a population of 70,000 people. Overhead electric wires will be used on the same principle as at Walsall.

The Victoria Embankment.—The London County Council postponed on Tuesday the Highways Committee's recommendation that the Victoria-embankment should be lighted from the centre of the roadway, the work to be carried out by the Works Committee. This matter had previously been referred back to the committee for reconsideration, as stated in our issue of the 16th ult.

City Lamp Figures.—At the beginning of 1893 the City of London Electric Lighting Company had 20,241 lamps connected to the system, with a current-supplying capacity equal to 32,000 lamps; in the middle of the year the figures were respectively 45,919 and 34,000; at the end of the year, 65,341 and 64,000; and at the present moment the figures are respectively 76,000 and 100,000.

Communication between Lightships and the Shore.—The land wires for the connection of the North Sands Head lightship on the Goodwins with the shore are completed, and nothing now remains to be done but to run the cable from the lightship to the shore at Ramsgate, a distance of about five miles. A telephone similar to those used in the postal service will be fitted up on the lightship.

Electrical Standards Committee.—A meeting of the Electrical Standards Committee was held last week at the Board of Trade, at which the following members were present: Sir Courtenay Boyle (in the chair), Mr. F. J. Hopwood, Major Cardew, Lord Kelvin, Mr. W. H. Preece, Lord Rayleigh, Prof. G. Carey Foster, Mr. R. T. Glazebrook, Dr. John Hopkinson, Prof. W. E. Ayrton, and Sir T. W. P. Blomefield, secretary.

Lighting in Notting Hill.—The directors of the Notting Hill Electric Lighting Company state that the prime cost of the generation of current during the second half of last year was lower than that appearing in any of the accounts of other London companies for 1893. The company has now been placed on a dividend-earning basis. The number of houses supplied has increased from 124 in 1892 to 173 in 1893, and the number of lights from 9,438 to 12,153 respectively.

Extensions of Mains.—The London County Council have sanctioned the laying by the House-to-House Electric Light Supply Company of mains in a part of Evelyn-gardens and on the east side of Drayton-gardens; by the Kensington and Knightsbridge Electric Lighting Company, of mains in Egerton-gardens and St. Michael's-grove; by the Westminster Electric Supply Corporation, of mains across Belgrave-road; and by the Charing Cross and Strand Electricity Supply Corporation, of mains in Green-street.

Electric to Compete with Steam Railways.—It is probable that the cities of Washington and Baltimore will soon be united by an electric railway in addition to the ordinary railways in existence. Work on this new line has commenced. The distance is about 35 miles. It is the purpose of the company to equip the line with model vestibule trains, making the journey in an hour, and charging one dollar for the round trip; that is, the same fare that is charged for the single journey by the steam railways.

Signalling between Ships at Night.—With a view to overcome the difficulties experienced in distinguishing between long and short flashes with incandescent lamps arranged on mastheads, experiments have been carried out in the "Undaunted," cruiser, and the "Hecla," torpedo storeship, with lamps in which each globe contained several filaments. The naval electrical experts are now reported to have invented a lamp, to be known as the multiple-fibre lamp, by which all difficulties are overcome, and the Admiralty have ordered all ships in the service larger than third-class cruisers to be supplied with these lamps.

Telegraphy in South Africa.—The British South Africa Company have been informed that a telegraph office has been opened at Tati, on the Matabeleland border. Information has been received at Cape Town that the Portuguese officials, acting on instructions from Lisbon, threaten to oppose the construction of telegraph lines between the British spheres of influence and Tete, on the Zambesi. This is the route which, it was intended, should be followed by the sections of Mr. Rhodes's projected overland telegraph line, to connect Matabeleland to the south of Portuguese Zambesia with Nyasaland to the north.

"The Book of the Fair."—Under this title the Bancroft Company, Auditorium Building, Chicago, are reproducing in book form, in the highest style of art, the features of the recent Chicago Exhibition. The book traces the evolution of the fair in all details, shows how it was built, who were its chief founders, and then pictures it not only in its general but in its special features. The book, which is being issued in 25 parts, at the price of one dollar each, will not be complete until the end of the summer. Two parts, Nos. 10 and 11, referring to the electrical section, have reached us. The illustrations are of the high-class kind characteristic of American ingenuity.

Transmission of Power.—This subject is engaging more attention every day, and the pamphlet issued by the Westinghouse Electric Company, Limited, entitled "Transmission of Power," comes at an opportune moment. Whilst this *brochure* is essentially a description of systems and apparatus furnished by the Westinghouse Company, the author (Mr. L. B. Stillwell) has embodied in it valuable information concerning the direct and alternating current systems of distribution. The numerous illustrations are excellent. The Tesla polyphase system is also fully illustrated and described, and the pamphlet concludes with details of auxiliary apparatus and switchboard instruments.

The Douglas Tramway.—It is reported that the directors of the Isle of Man Tramway Company have recommended the shareholders to accept an offer from the Douglas and Laxey Electric Tramway Company to purchase their property for £38,000. They point out that four years hence the Douglas Commissioners have power to acquire the undertaking at the then value, exclusive of all allowance for past or future profits or compensation. In the face of this statement, it is difficult to understand why the electric tramway company wish to acquire the line. If the Commissioners, as stated, may compulsorily take possession of the tramway in four years, how is the line to prove a commercial undertaking to the proposed new owners?

The Aberdeen Central Station.—As foreshadowed in our last issue, this central station was set in operation on Tuesday. The ceremony of turning on the light took place in the Joint Town and County Hall, and was performed by Mrs. Stewart. The works now completed are capable of supplying 10,000 lamps of 8 c.p. The total cost of the installation, including buildings, machinery, etc., has been £21,500, which is under the estimate of Prof. Kennedy—set down at £24,000. After the ceremony the station was thrown open to the public, and large numbers of people availed themselves of the opportunity of inspecting the works. Mr. Ruthven Murray and his staff received the visitors.

New Issue by the City of London Company.—The City of London Electric Lighting Company, Limited, as will be seen from our advertisement columns, are inviting subscriptions for additional capital. The present issue is £100,000 5 per cent. debenture stock at the price of £115 per cent. (part of a total issue of £400,000), redeemable by the company at £125 by six months' notice after December 31, 1910. The subscriptions to the debenture stock are payable as follow: £10 on application, £25 on allotment, £40 on April 30, and the remaining £40 on June 30 next. The prospectus states that applications from preference and ordinary shareholders will be preferentially considered. The list of subscriptions opens to-day (Friday), and will close at four o'clock this afternoon.

"Spons's Architects' and Builders' Price-Book." Messrs. E. and F. N. Spon have just published the 1894 edition of this price-book, which is edited by Mr. W. Young, architect. The book contains, besides the information relating to prices, numerous memoranda and tables, and the handy arrangement of the matter in alphabetical sequence, thereby rendering it easy to turn up in a moment any desired formula, has been adhered to as in former editions. The present issue has been revised and enlarged, and among the additional information embodied in it may be mentioned a chapter on electricity and complete specifications and estimates of electric lighting installations carried out in different places. Moreover, extra divisions have been provided on concrete, fireproof floors, and granite.

Personal.—Many of our readers will doubtless be surprised to hear that two gentlemen well known in the electrical field are severing the connections they have held for so long in their respective avocations. We refer to Mr. Edwin J. Houston, professor of Physical Geography and Natural Philosophy in the Central High School of Philadelphia, who has held this chair for the past 26 years and who has just resigned; and Mr. A. E. Kennelly, who during the past six years has been Mr. Edison's right-hand man and chief electrician, and who is about to leave the latter's laboratory. These gentlemen have decided to establish in Philadelphia a firm of electrical experts to be known as Messrs. Houston and Kennelly. It is scarcely necessary to remind our readers that Prof. Houston is president and Mr. Kennelly is one of the vice-presidents of the American Institute of Electrical Engineers. We wish them success in their new undertaking.

"Waste Field" Measurements.—We recently came across an ingenious young electrical engineer who was a good deal employed in equipping and starting up the smaller types of self-contained lighting installations: and the method which he asserted was of great use to him in roughly comparing the qualities of different generators had at least an air of refreshing novelty. He was the proud possessor of a common easily-magnetised silver watch, whose movements were remarkably erratic according to the particular machine alongside which its owner would be working. The latter claimed that the waste field is very nearly proportional to the retarding effect upon his watch: Smith's machines are better designed than Brown's, because they only make it lose half an-hour a day instead of three-quarters. We advised him to develop the idea, and waste the product of his father's fields (he was a farmer's son) by taking out a patent for a pocket Aron meter, or horological magnetometer!

The Battersea Polytechnic.—The Prince of Wales on Saturday formally opened this polytechnic institute, to which reference has been made on previous occasions. The institute is under the direction of a governing body composed of representatives of the South London Polytechnics Committee, the London County Council, the City Parochial Charities, and the London School Board. The principal ornamental decorations consist of 10 statues, which represent Architecture, Painting, Engraving, Sculpture, Music, Poetry, Chemistry, Electricity, Mathematics, and Engineering. The institute embraces workshops for various trades, physical and chemical laboratories, art-room, photographic-rooms, and numerous classrooms and lecture-halls. Instruction in the following subjects is provided: carpentry, technology (including instruction applicable to plumbing), patternmaking, mechanical and electrical engineering, and the chemical trades; science generally, in accordance with the regulations of the Science and Art Department, etc.

New Form of Induction Balance.—Mr. M. Wien has described a new form of induction balance in a German contemporary. In this form of induction balance the arrangement is very simple, being that of a Wheatstone's bridge, two arms of which are coils having self-induction, and the other two inductionless resistances. A sine current of $\frac{n}{2\pi}$ periods per second flows through these arms, and the telephone which forms the bridge arm is silent when both resistances and self-induction are proportional. Now, if a piece of metal be brought near one of the coils, the balance is disturbed. The coil itself is disturbed, and not the mutual induction of two coils, as in the old form of balance. When balance is restored by suitable adjustment of a secondary coil inside the other inductive coil, the time constant of the metal piece is equal to that of the compensating secondary coil. From this datum the conductance of various metals of similar form may be compared. The paper is an interesting one, and contains an archipelago of experiments surrounded by a sea of mathematics, in which the navigator has some difficulty in keeping his bark afloat.

Loakage from Underground Cables.—Mr. Weir, M.P., is much concerned about high-tension circuits. On Monday, in the House of Commons, he asked the President of the Board of Trade whether his attention had been called to a letter in the newspapers by Mr. James Keith, C.E., stating that outside the precincts of the Houses of Parliament more than ordinary danger from high-tension electric currents had to be faced, seeing the public streets around or near the legislative chambers were intersected in almost every direction by underground high-voltage electric cables, and what could so easily happen under 2,000 volts in Bournemouth might, under certain conditions, and under a higher voltage, perhaps occur more easily in the streets of London; and whether any effective means of dealing with leakage of high-voltage electricity in underground cables had yet been placed at the disposal of the Board of Trade. In reply, Mr. Mundella said that he had seen the letter in question, and that in 1890 the Board of Trade made regulations with regard to high-tension electric currents, in consultation with the Council of the Institution of Electrical Engineers, and these were considered to be quite ample protection.

A Method of Cooling Transformers and Conductors.—In order to carry off the heat generated in transformers working under a heavy load, Prof. Henry A. Rowland, of Johns Hopkins University, has invented a method employing a current of liquid led through the iron in tubes so placed as not to be cut by the lines or magnetic induction, the tubes and iron laminæ alternating with one another. Water, or any other conducting liquid, may thus be employed without interfering with the proper working of the transformer. According to the *Electrical Engineer* of New York, another method employed by Prof. Rowland is to surround the transformer with a vessel containing a volatile liquid, which, by boiling, carries away the heat. The vapour may be recondensed in the upper part of the vessel or carried off through a condensing coil and returned to the vessel in a liquid state. He also provides means for reducing the pressure in the vessel, in order that the liquid may boil at a low temperature. To cool conductors carrying heavy currents, Prof. Rowland suggests making them hollow and passing a current of cooling liquid, such as water, through them from end to end, the liquid issuing in the form of spray to break the continuity of the stream and thus insulate it from the vessel into which it flows.

Mason College, Birmingham.—"Founder's Day" of this college was celebrated a few evenings ago by a dinner, under the presidency of Lord Kelvin. In proposing "The College," his lordship said engineering, mechanical, civil, and electric, formed one of the departments of Mason College. Under the able Prof. Robert Smith admirable work had been done. All admired the great energy, the great knowledge, and the great skill and capacity for acting with which that department was worked. But it wanted strengthening obviously. It wanted strengthening in the way of addition to its *personnel*. They could scarcely strengthen the *personnel* itself, but they wanted one more professor, and certainly additional lecturers, and the means and appliances for an engineering laboratory. The modern estimate for an engineering laboratory was £25,000. Surely £25,000 could be found for an engineering laboratory in the Midlands University. The chemistry department had good laboratories. When he turned to the physical laboratory he found there was still much to be done. They wanted a strong physical laboratory. He thought the citizens of Birmingham might take more advantage of the college than they did. Instead of there being the present inconsiderable number of students—600, or 700, or 800—there ought to be at least 2,000 in such a college.

An Electrical Parcel Van.—Following up the experiments made by Mr. Radcliffe Ward with electric vehicles for operation on our streets, another attempt is about to be made to render this method of traction popular and successful. This time it is Messrs. E. J. Clubbe and Co., of 16, Elm-street, Gray's-inn-road, W.C., who are interested in the matter, and who will shortly place on the streets an electrical parcels van fitted with Fitzgerald's improved secondary batteries. By a careful arrangement the working parts of the van are reduced to a minimum, leaving the whole of the interior of the body free for passengers or goods. The accumulators supplying the motive power are suspended in a special carrier beneath the body of the van, and a recharged set may be substituted in two minutes. The van is lighted by electricity, and is controlled by a single switch giving six degrees of speed. The company estimates that the cost of working a van by electricity equal to a two-horse vehicle, including charging, maintenance, etc., will be 2d. per mile run. The car will run a distance of about 30 miles before recharging of the batteries becomes necessary. The body of the vehicle was built by Messrs. Liversedge and Sons, the mechanical parts by Messrs. Easton and Anderson, Limited, the motors were supplied by Messrs. J. G. Statter and Co., and the vehicle was designed by Mr. Walter C. Bersey.

The Pacific Cable Question.—The Premier of Queensland (Sir Thomas M'Ilwraith) arrived in London on Wednesday. He will during his stay on this side attend

Digitized by Google

to the inter-colonial cable and mail route questions. Interviewed by a correspondent, Sir Thomas stated he had seen all the Canadian Ministers on the subject of the cable, and had also interviewed leading Americans. He said nothing but a British cable was contemplated, which, if established, would prevent an extension of the French cable from New Caledonia to Vancouver, as it was not intended to lay two cables. In this connection, the *Pall Mall Gazette* says: "Now that it is fixed that there is to be an intercolonial conference at Ottawa next June, one can only hope for one thing. That is, that the Imperial Government will show some interest, even a slight interest, in a meeting called in response to the unquestionable enthusiasm of the colonials. Canada, Australia, New Zealand, (and Hawaii) are to be represented. The main points for discussion are the new Pacific cable and the proposed Pacific Steamship Company which is to run (under subsidy) from Vancouver to Australia. Both will be obvious advantages to the Empire as the keen eyes of Younger England see plainly enough. It is ridiculous that a French monopoly should hold the only telegraphic bridge between Canada and Australia, and a very inefficient one. The sooner we bestir ourselves the better for our colonies and for us."

Sewage Purification at Worthing.—The experiments in electrical sanitation, to which we have referred in recent issues, commenced at Worthing on Monday. M. Hermite attended to explain to the mayor and Corporation the essential parts of his system. Arrangements have been for some weeks past in progress, the scene of the experiments being a row of small cottages in West-street. The experimental plant is erected in a contractor's yard near at hand, where a dynamo and engine are situated. To the mayor and Corporation, and to a number of local medical men, the system was explained by the inventor, and by Mr. Cooper, an electrical engineer who had been associated with him in his experiments in France. The necessary bacteriological and chemical analyses, which are to determine the practical value of the invention, are being undertaken by Sir Henry Roscoe and Dr. Armand Ruffer, the president and secretary respectively of the British Institute of Preventive Medicine. After an inspection of the operations, the party went to the Council-chamber, where a number of questions was put to the inventor. M. Hermite said as to the cost, it was found that the disinfecting solution could be brought to the houses for about one shilling per head per annum. This would give about nine gallons per head, which would suffice not only for flushing purposes, but also for washing floors, and for use in sick-chambers. By the adoption of the system, he believed it to be possible to do away with diseases of many sorts, and to make a perfectly healthy town; but to do that the electrolysed water must be distributed in every house. It might be supplied to consumers in the same way as gas or electricity, and thus become a source of municipal income. It was stated by the mayor that the representatives of a large number of municipal bodies in the kingdom were anxious to witness the system in operation, and it was understood that they would be communicated with, so that they might inspect the system in operation.

Are Horses "Peculiarly Susceptible to Electric Shock"?—This question has arisen in connection with the recent accident at Bournemouth. "The answer," the *Lancet* observes, "will depend upon the sense in which the word 'susceptible' is used. Used as it is here, it would seem to imply that an electric current on entering the body meets with some anatomical peculiarity or physiological 'susceptibility' that makes the horse more vulnerable than other animals to the action of such a current. In this sense it is difficult to see good grounds for the statement. If, however, it is intended to say that the conditions under which horses usually work facilitate the access of electric currents to the body the statement has doubtless good foundation. The hoof, and more particularly its crust and sole, is a good insulator, but, being shod, there is not only presented to the ground a large metallic contact, but this contact is in connection with metallic conductors in the shape of nails, which pierce the strongest part of its insulation and afford an easy electrical path into the body. The great superincumbent weight of the animal is another element in improving the contact with 'earth.' Further, it may often happen that in passing over wet ground the external surface of the hoof and the hair of the fetlock, especially in the case of untrimmed horses, may become sufficiently wet to form a good surface conductor, and so carry a current directly from the earth to the upper part of the body, thereby eliminating the safety afforded by the natural 'resistance' of the hoof. It is also to be remembered that a horse, covering more ground than a man, will be in contact with points of ground further apart, and thereby risk is increased. These considerations do not, of course, touch the question of accidents to horses during thunderstorms. In these cases the animal is often killed by what is known as 'return shock' (the sudden discharge of an insulated conductor), and here the insulation afforded by the hoof, so far from being protective, becomes an additional element of danger."

Experiments on Electro-Dynamic Screening and Electric Shadows.—A paper has been published in *Wiedemann's Annalen* by Messrs. H. Ebert and E. Wiedemann dealing with this subject. The authors have set themselves to thoroughly investigate the question already examined by Hertz and Stefan, and used for the purpose the parallel wires described by Lecher, connected by a conductor at one end, and at the other joined up to two condenser plates standing parallel to one another. When an exhausted and electrodeless tube is brought near the condenser, it is illuminated so long as the primary spark is passing, and consequently its extinction is a mark of screening from electrical oscillations. In the experiments described in the paper, the vacuum tube and the screening body were placed with their length parallel to the axis of the condenser, and away from the parallel wires; and the order in which they were arranged was either—condenser, screen, tube, or condenser, tube, screen—according as the experiments were on screening in front or behind. If the screen was not a wire or tube, but a metal plate, then the question of direction of its plane was also a factor to be noted. It was found that screens of metal, or of any substance which screens behind itself, shield also in front and alongside themselves. The thinnest sheets of metal, even when transparent (like gold leaf), are screens; tubes also filled with a solution of electrolyte, even when very weak; but insulators, such as glass and mica, do not screen. The dielectric in which the screening body is placed has not observable influence on the result. If the screen is to work at a distance of 1cm. from the tube, it must be at least one-third to one-half of the length of the column of light, and when moved further away must be longer still to entirely quench the light. Tubes filled with rarefied gases do not screen in themselves, but become shields if made to glow by electric oscillation. The authors sum up as follows: Round conductors there is produced under the influence of electrical oscillation a screened space, both in front, behind, and alongside; and excitable bodies placed in this space are not excited so long as their capacity for excitation is not too great in comparison with the screening

Digitized by Google

action at that point; and luminous gases take part in this property of conductors.

The Cultivation of the Inventive Faculty.—A pamphlet on this subject has been written by Mr. B. H. Thwaite, A.M.I.C.E., F.C.S., etc., who concludes that the cultivation of the inventive faculty in this country would be greatly assisted by the adoption of the following suggested list of reforms in our laws relating to patents for inventions: "(1) The reduction of the patent charges to the level of those of the United States of America, and to cover a period of 17 years instead of 14 as at present. The payments to be £2 on application and £5. 10s. on completion. (2) The provision of officially approved and Government paid agents in suitable centres of population to guide inventors in the preparation of their patent documents before lodgment. A nominal sum, depending upon the character of the invention, number of drawings, and length of specification, to be charged. Present chartered patent agents might be appointed to the official position. (3) A commission of experts shall, whenever possible, examine working inventions in actual, industrial, or other use. If such reasons are of a financial character, and if the commission of experts decide favourably, conditional financial advances are to be made to enable the invention to be worked. (4) The examination of the claims of the inventor to be made by officially appointed, highly technical, scientific and other experts. (5) Patent case disputes to be decided by a tribunal composed of technical or other experts, no legal counsel to be permitted on either side. List of interrogations to be drawn up by the expert tribunal. (6) If the inventor is aggrieved by an infringement, and he shall give satisfactory proof of his financial inability to obtain satisfaction, the Government shall be permitted to provide the necessary aid to enable the inventor to obtain justice. (7) In the event of the non-working of the invention after a specific period—to be determined—the inventor to show satisfactory reasons for such inaction. (8) Orders of merit to be granted every year for the best invention relating to every important industry or for the creation of a useful new one. (9) The Government shall issue a list of improvements required in different branches of industry, to the solution of which the faculty of invention might be usefully applied."

Hotel-Lighting.—Although some little surprise might naturally be felt at the installation of self-contained electric lighting plants within areas already supplied by street mains, it is hardly to be wondered at that such should still exist in places where they have worked efficiently and economically for some years. The authorised price per unit of supply from a public electric light company in nearly all cases proves much higher than the cost incurred by operating a plant of large size; and the owners of self-contained installations are not therefore likely to throw out their generating plant from a public-spirited wish to help in eventually reducing the price of supply from street mains to what it now costs them. Even in the centre of the Metropolis there are, therefore, many complete installations, some of which have been at work for years, and which will probably continue to be operated until the need for extensive repairs or additions make it preferable to take supply from outside. Amongst such may be mentioned the plant engaged in lighting the Cannon-street Hotel and offices. Here, in a small yard at the side of the railway station, is a very compact little building which contains a loco.-type steam-boiler by Hornsby—of 90 h.p.—with Berryman feed-water heater, Holden and Brooke's automatic injector, as well as a Worthington pump, supplying steam to a couple of Willans compound engines, one of 60 h.p. and the other of 38 h.p. These are coupled direct to two Castle dynamos by Holmes and Co.—one shunt wound, giving 300 amperes at 115 volts, the other compounded, with an output of 180 amperes at the same pressure. The latter machine is provided with a switch for throwing out of circuit the series winding when it is necessary at full load to run both dynamos in parallel. Six main circuits are taken into the hotel and station buildings, with sub-main boards and distribution boards. The Great Hall—measuring 80ft. by 40ft. by 40ft. high—is wired in ring fashion, with feeders brought in at six equidistant points, forming practically six separate sections, each governed by a switch. The current from the main switchboard in the generating station passes through an Aron meter capable of registering up to 800 amperes. The credit of designing and carrying out the entire installation—generating plant, distribution, wiring, etc.—is due to Mr. W. Durtnall, A.I.E.E., who acts as electrical engineer to the hotel proprietors.

The Tesla High-Potential Conductor.—In order to prevent loss by dissipation or interference by induction on line conductors carrying high-potential alternating currents, they have in some instances, such as at Deptford, London, been insulated and enclosed in a continuous conducting sheathing, which is connected with the ground by a good conducting path. The *Electrical Engineer* of New York states that, while conducing to the safety of the system, Mr. Tesla has found that the use of a conducting sheath or screen around the line conductors and well grounded, or even brought into proximity to external conductors or large bodies, is attended by an actual, and generally a serious, loss of energy, which is the greater the greater the number of alternations and the higher the potential. He therefore maintains the sheath entirely isolated or connected directly or inductively to the ground, through a path which will practically prevent the passage of currents over it. He has also found that when a continuous isolated sheath or screen is employed, there is greater liability to loss of energy by inductive action; for unless the sheath or screen be considerably shorter than the current waves passing in the conductor, E.M.F.'s will be set up between different points in the sheath, which will result in the passage between such points of induced currents. Mr. Tesla therefore divides up the sheath or screen into short lengths very much shorter than the wave lengths of the current used, so that the grounding of any one of such lengths or the approach thereto of a large body will result in an inappreciable loss, or at most a small local draining of the energy, while the tendency of currents to flow between different points in the sheath is effectually overcome. The function of the sheath as a static screen for preventing the dissipation of the electric energy, however, requires for its complete effectiveness an uninterrupted conducting partition or screen around the conductor. In the case of a sectional screen this is obtained by causing the ends of the insulated divisions or sections to overlap, and interposing insulating material between the overlapping portions. For transmitting currents of very high potential and very high frequency, Mr. Tesla provides between the sheath and the ground a path of very high ohmic resistance, or one containing a self-induction coil properly determined with respect to the existing conditions so that it will effect the desired result, or a condenser of very small capacity. In such cases the sheathing or screen for practical purposes may be regarded as isolated from the ground, since by the character of the connection employed no appreciable loss results from the passage of current from the sheath to the ground.

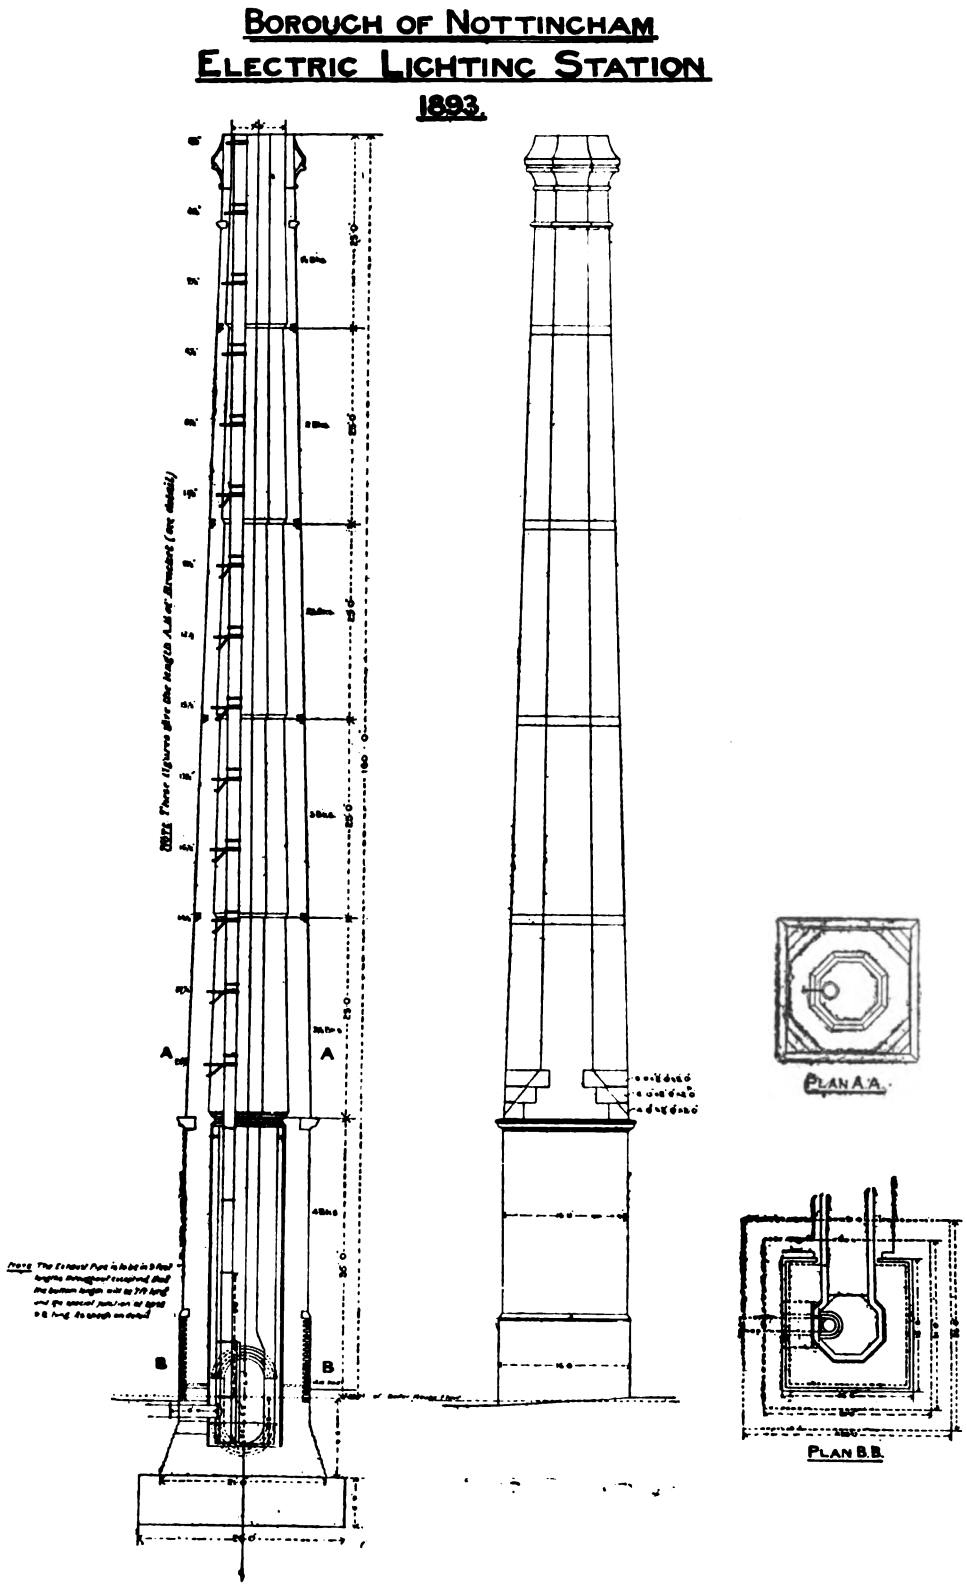
engine-house is 40ft. by 40ft. and 24ft. high to springing of roof. The foundation for the engines is composed of one concrete block 34ft. by 30ft. by 9ft. 6in. deep, and this is separated from the bottom bed of rock by four layers of felt. A subway 4ft. by 6ft. 6in. has been formed in the centre of the bed, with brackets built in the sides to facilitate the carrying of the cables from the dynamos to the switchboard.

There will be six machines of the following output: three dynamos, each of 370 amperes at 220 volts; three dynamos, each of 330 amperes at 145 volts. They will be mounted on combination frames and coupled direct to the fly-wheels of the engines. Copper pipes will be used for connecting the engines to the main steam and exhaust pipes. The three large dynamos will be used for running on to the outside feeders of the three-wire



Elevation and Section of Chimney Shaft, showing Exhaust-steam Pipe carried to the top.

The contract for the engines and dynamos has been placed with Messrs. Siemens Bros. and Co., Limited. The engines will be of the Willans central-valve compound type, single acting, having all brasses in constant thrust. There will be three engines of 80 h.p. each and three of 134 h.p. each, and space on the foundation for an additional one of each size. The dynamos will be of the Siemens type, shunt wound, with single magnetic circuits and bar armatures. system, and the smaller machines will be used for charging the batteries or for balancing between the middle cable and either of the outside distributors. The main switchboard is being supplied by the Electric Construction Company, and is arranged for manipulating the machines, batteries, and feeders. A five-ton traveller has also been supplied for the engine-room by Messrs. Marshall, Fleming, and Jack. The battery-room adjoins the engine-house, and is 40ft. by

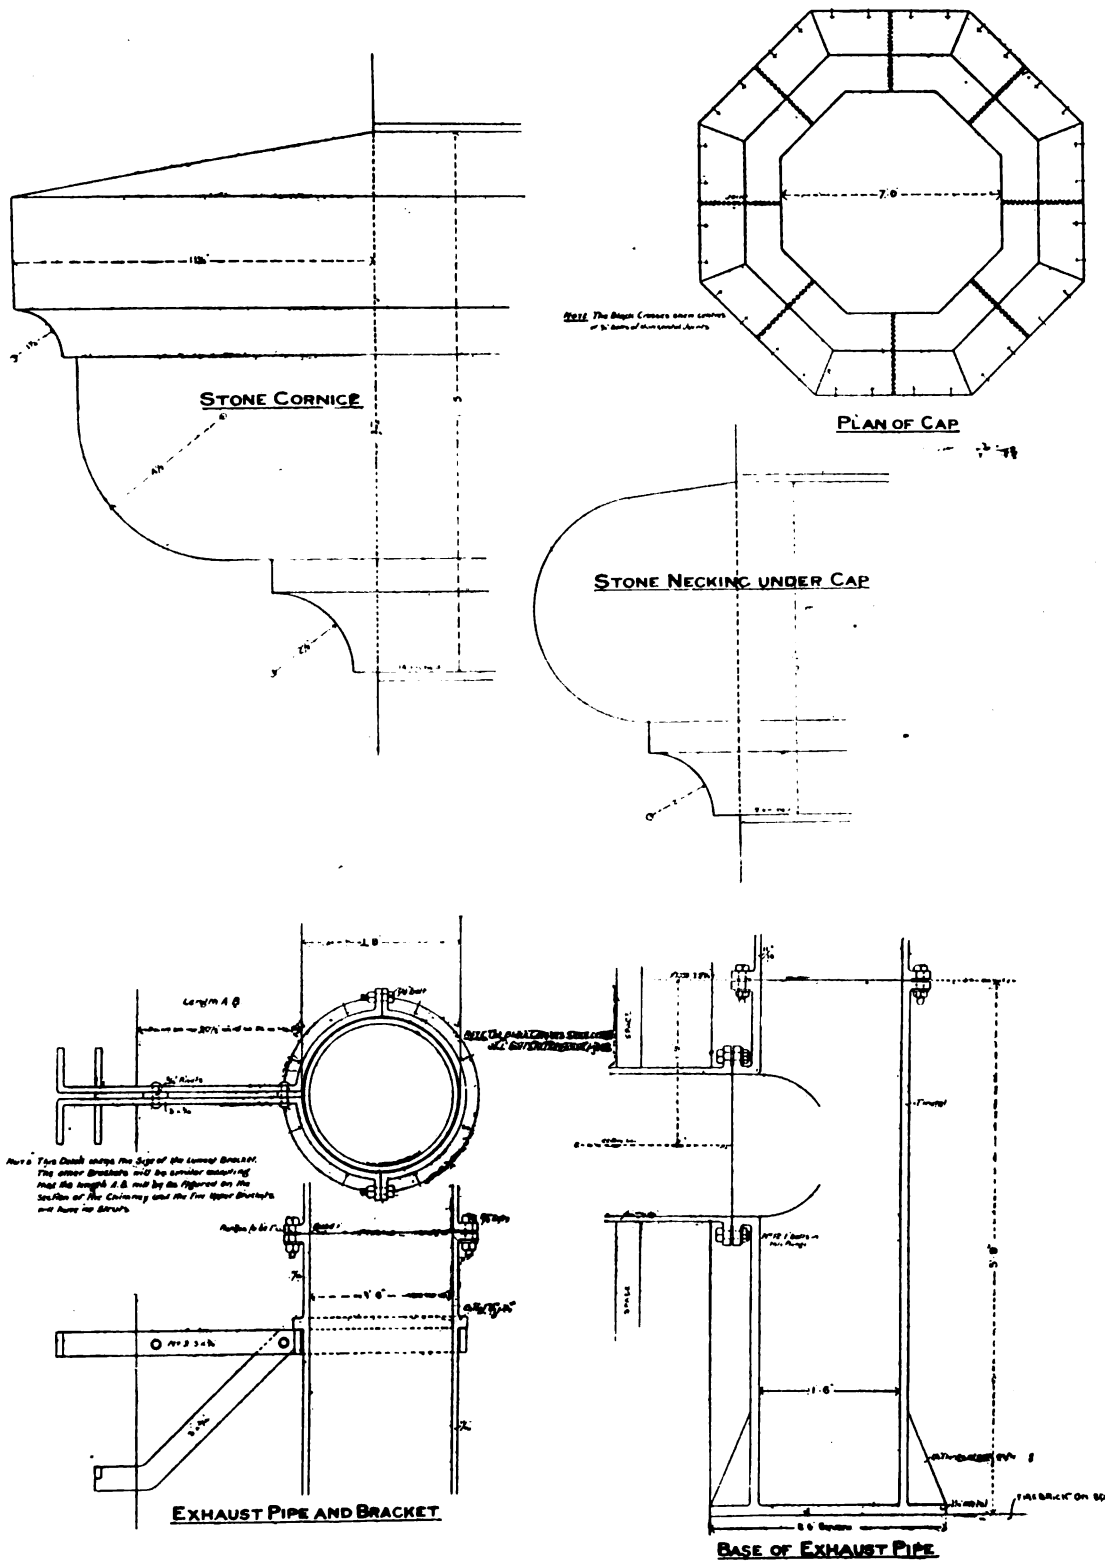
Digitized by Google

20ft., and the floor will be paved with Val de Travers asphalte. A battery of 112 K-type cells is being supplied by the Electrical Power Storage Company, Limited, and is to be capable of giving 150 amperes at 212 volts for seven hours, or 500 amperes at 210 volts for one hour.

From the main switchboard brick subways for cables have been laid to each street upon which the station abuts, and from thence along and through the 18 streets named in the order conduits have been laid on the Callender-Webber draw-in system. The contract for this work, including the laying of the conduits and the running of the cables, has been let to Messrs. Callender's Bitumen, Telegraph, and Waterproof Company.

The chimney will be 160ft. high above ground-level, and 16ft. 6in. square at the base; the flue will be 7ft. across the octagon at ground-level, and the main exhaust steam pipe, 18in. diameter, will be carried inside the chimney to the top.

The buildings are being constructed of brick with Derbyshire stone dressings, glazed bricks being used for facing the inside walls of engine and boiler house and battery-room. The buildings are so arranged that when the demand for light increases, the engine and boiler house may be extended on the west side thereof. The contract for the buildings and chimney was let to Mr. Messom, of Nottingham, and the work is now being very rapidly pushed forward. It is unfortunate, however, that there has been a delay of over three months in the erection of the buildings, as in consequence of the dispute in the coal trade it was impossible to obtain a supply of glazed bricks. It is expected, however, that the station will be completed by about next July.



Nottingham Electric Light Station—Plan of Cap, and Illustrations of Stone Cornice, etc.

TESTING CIRCUITS.

When the leakage current exceeds the fixed amount allowed, or when the insulation resistance falls below the fixed standard, whatever this amount or standard may be, then the circuit must be considered as faulty or defective, and should at once be tested so as to locate and remove the fault. Sometimes the falling away of the insulation resistance cannot be traced to any particular point. In that case, it is most probably a general deterioration of insulation throughout the circuit, and nothing can be done except take down what appears to be the worst section, and replace with new mains. Faults may be divided into two classes—(I.) partial earths, (II.) dead earths.
